Objectives: To describe geographical trends in suicide rates in Italy over the period 1997-2001.

Methods: Death rates were analysed as age-standardized mortality rates by gender and age, for regions and province. Mortality data, obtained from the Italian Population Register (ISTAT), are based on the ICD-9-CM.

Results: 20,944 suicides were reported (15,849 males and 5,095 females). Males had a higher risk than females (RR=3.11): the mean annual rate per 100,000 was 11.5 and 3.5, respectively. Rates showed a steady downward trend in the 5-year-period. Regional rates were highest in the north (by region, the highest rates were seen in Val d’Aosta 26.8/100,000 male and 7.6/100,000 female) and in Sardinia (20.8/100,000 only in males), followed by Trentino-Alto Adige, Friuli-Venezia Giulia, Piedmont (especially in the northern provinces), Emilia Romagna, Marche, Umbria with rates between 13.2 and 15.9/100,000 male and between 4.1 and 4.9/100,000 female. The South has the lowest overall risk in both sexes (8.9/100,000 males, 2.6/100,000 females). Rates increase gradually with age in both sexes and are highest among men aged 65 years and older. The most frequent method is hanging (46%) and firearms (18%) for men and jumping (39%) and hanging (30%) for females.

Conclusions: Biopsychosocial, environmental and sociocultural risk factors (sex, marital status, employment status, social class, social isolation, misuse of alcohol, substance abuse, prior suicide attempt, immigrant status, previous loss, bereavement, psychiatric illness or family history of psychiatric disorder, physical or sexual abuse, severely stressful life events) can act synergistically in vulnerable individuals at different ages in Italian regions.

EFFECTS OF rTMS AND ECT ON MEMORY OF DEPRESSIVE PATIENTS RESISTANT TO ANTIDEPRESSANTS TREATMENT

INSTITUTIONS
1. Moscow Research Institute of Psychiatry, Moscow, Russian Federation

AUTHORS
1. Olga Pugovkina¹, PhD, olgapugovkina@yandex.ru
2. Alla Kholomgorova¹, PhD, psylab2006@yandex.ru
3. Eduard Tsukarzi¹, MD, psylab2006@yandex.ru

Objectives: The aim of this study is to evaluate changes in cognitive functioning as possible side effect of ECT and rTMS in treatment resistant depressive patients.

Methods: 40 patients with recurrent depression (HAM-D > 17) meeting resistance criteria were randomized into 2 groups: group A was treated with ECT (20 patients), group B - rTMS (20 patients). Changes in memory activity related predominantly to the effect of applied therapy were studied by a battery of psychological tests, assessing verbal and non-verbal memory: Remembering a list of 10 words (Luria A.), Benton Visual Retention Test (BVRT). Test battery was applied before the course of stimulation, on 7th day, on 14th day - at the end, and a month later the end of the therapy.

Results: In group A we observed no considerable correlation between the level of cognitive functioning and Depression Scale’s scores by the end of therapy process. In spite of improvement of depressive symptoms (responders 65% of patients, decrease of depressive symptoms more than 50% at HAM-D), memory parameters in these patients could be impaired. In group B (responders 55% of patients) were marked significant improvement of non-verbal memory (BVRT - 30.4% increase, p<0.05), and verbal memory (8.7% increase, p<0.05). As compared with level of healthy persons, memory level of depressive patients was significantly low even after the course of rTMS (p<0.01).

Conclusions: rTMS have no negative effect on memory as contrasted to ECT.

LIFE EVENTS AND DEPRESSION IN A TUNISIAN POPULATION

INSTITUTIONS
1. Razi Hospital, Department of adult psychiatry C, La Manouba, Tunisia

AUTHORS
1. Lilia Zaghdoudi, Dr, PhD
2. Soumeyya Halayem Dhoubi, Mrs, MD, soumeyyadhoubi@yahoo.fr
3. Rym Rafrafi, Dr, PhD
4. Meriem Ben Ammar, Dr, MD
5. Raja Labbène, Dr, PhD

OBJECTIVES: Life events have been proved to be susceptibility as well as precipitating factors in depression. Previous studies have found more negative life events such as death in the family, couple difficulties, professional difficulties among depressed patients. This work aims to study the characteristics of precipitating life events in the two years preceding the beginning of depression in the Tunisian cultural context.

METHODOLOGY: It is a case-control study. The Patients assessment was conducted in the outpatients section of the department of Psychiatry C, in Razi Hospital La Manouba. Controls have been assessed in a community clinic in La Manouba. Patients suffering from major depression disorder according to DSM IV criteria were assessed. Were excluded patients suffering from: schizoaffective disorder, organic disorder responsible for depression, substance use or abuse, cognitive disorders, and also patients who have been hospitalised in a psychiatric department. Controls have been matched for gender and social parameters. They shared the same exclusion criteria. For all patients and controls: -A form was filled in to assess epidemiological, medical, family and personal antecedents, and therapeutic data. -The live events questionnaire of Amiel-Lebigre was filled in.

RESULTS: 150 patients and 150 controls were assessed. Life events were significantly more frequent in patients (p=0.00). The most frequent precipitating life events were: death in the family (34.43%), couple difficulties (28.5%), professional problems (12.58%), and being into debt (10.66%).

CONCLUSION: Our results are in accordance with the ones reported in previous literature.

SUICIDE RATES AND MACROECONOMIC INDICATORS IN INDIA: ECOLOGICAL STUDIES

INSTITUTIONS
1. Christian Medical College, Psychiatry, Vellore, India

AUTHORS
1. Anto Praveen Rajkumar, Dr, MD, DPM, antoprajkumar@cmcvellore.ac.in
2. P Senthilkumar, Mr, taskforce_cmcvellore@yahoo.co.in
3. G Shyamsundar, Dr, drsam_111@rediffmail.com
4. KS Jacob, Prof, MD, MRCPsych, PhD, ksjacob@cmcvellore.ac.in

Objective: We tested the hypothesis that annual national suicide rates and suicide rates in the different states and union territories in India are associated with macroeconomic and other indices.

Method: We compared suicide rates with macroeconomic, health and other indices using an ecological study design for India and for the different states and union territories. Available information from the following sources were employed: National Crime Records Bureau, Ministry of Finance, Labour Bureau, Government of India and of Tamil Nadu, population commission and planning commission official portals, world bank group and the United Nations.

Results: The ecological analysis of data from India documented a relationship between per capita Gross Domestic Product, economic inequality index (Gini coefficient), consumer price index and the Trade Balance. Data from the different states in India documented the relationship between suicide rates and per capita income, economic inequality index and literacy.

Conclusion: Macroeconomic indices are associated with suicide rates in India suggesting that macroeconomic policies may impact suicide rates.

According to recent findings, clinical symptoms in patients with disorder (OCD) may be related to dissociation. Aims: The aim of the present study was to evaluate relations between measures of dissociation, psychopathology and cognitive function in obsessive-compulsive disorder.

Methods: The study sample comprised of 33 patients with OCD (18 females). Obsessive-compulsive symptoms, anxiety and depression were assessed by objective and subjective rating scales. Dissociation was quantified by the Dissociative Experiences Scale (DES) and the Somatoform Dissociation Questionnaire-20 (SDQ-20). Attention, verbal memory and cognitive inhibition were evaluated by the Stroop Color and Word Test, the Continuous Performance Test (CPT-II) and the Auditory Verbal Learning Test (AVLT).

Results: Positive correlation was found between obsessive-compulsive symptoms as assessed by the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) and dissociation examined by DES and SDQ-20. Y-BOCS score correlated positively with severity of anxiety and depression. The level of dissociation assessed by both, DES and SDQ-20, correlated positively with anxiety and depression. Between OCD patients and normative population samples there were no differences in performance on AVLT and interference time of the Stroop task. No significant relationship was found between the neuropsychological assessments and dissociation.

Conclusion: Our results suggest a possible relationship between dissociative symptoms and severity of obsessions and compulsions. However, the question remains to determine whether and to what it may be mediated by anxiety and depressive symptoms.

ACTION OF ALPRAZOLAM ON CHEMICAL MEDIATORS OF ALLOSTATIC LOAD IN ANXIETY AND STRESS

INSTITUTIONS
1. Instituto de Biodiencia Henri Laborit, Córdoba, Cordoba, Argentina

AUTHORS
1. Carlos A Soria1, Dr., MD, csoria@infovia.com.ar
2. Carolina Remedi1, Dr., MD, cremedi@infovia.com.ar
3. Adriana Faletti1, Dr., adrianafaletti@yahoo.com.ar

Objective: Assessment of the action of Alprazolam (0.5 / TID) on chemical mediators of allostatic load, in anxiety and stress disorders.

Methods: Twenty six patients (16 female, 10 male), ages 18-71 (range 44), with three or more clinically or biochemically verified items of allostatic load, score of six or more on Hamilton Anxiety Scale (HAS), and score of 60 or more within dimension of neuroticism on NEO-FFI personality scale, were included within study. The previously mentioned battery was applied on days -7,0,7. Lab tests included plasma measures of total cholesterol, HDL, LDL, glucose, haemoglobin, dehydroepiandrosterone, testosterone, C reactive protein, albumin, fibrinogen and saliva samples of MHPG and cortisol and plasma cortisol.

Results: No relevant records within parameters between days -7 and 0. Significant reduction of anxiety as scored at day 7 (p<.001) by HAS which correlated ultimately with reduction of MHPG and saliva and plasma cortisol and plasmatic noradrenaline. Global assessment of allostatic parameters suggested different clusters.

Conclusions: Action of Alprazolam appears to go beyond its anxiolytic effects and shows impact on primary and secondary mediators of stress and anxiety. Further studies could validate or exclude its use as phenotypic marker and facilitate the integration of compound phenotypes, in relation with endophenotypes and allelic variables of interest.

COMBINATION THERAPY OF DEPRESSIVE DISORDERS BY ANTIDEPRESSANTS AND ATYPICAL NEUROLEPTICS.

INSTITUTIONS
1. Yaroslavl State Medical Academy, Russian Federation

AUTHORS
1. Irina V. Lobanova, Mrs.
2. Alexey S. Ritskov, Mr., PhD
3. Alexey L. Djakonov, Mr., PhD

95 patients at the age of 18 till 45 years recurrent depressive disorder have been surveyed. The duration of disease 7.20±1.03 years, amount of episodes 4.3±0.83. All patients were divided into 2 groups treated by: fluoxetine (40mg/day) with olanzapine (10-15mg/day) combination - 62 patients; sertraline (100-150mg/day) with amisulpride (50mg/day) combination. Depth of depression on HAM-D scale made, on average: at baseline - 29.1 in the first group, 28.09 - in second, on 10th day of therapy - 26.3 and 18.58 points; 20th - 19.7 and 15.06; 40th - 10.7 and 7.63, accordingly. By the 10 day of therapy statistically significant improvement of depressive symptoms was observed at treatment by sertraline and amisulpride combination, but the end of the third and sixth weeks of therapy results in both groups were leveled. By the 40 day of therapy in the first group of patients "very good" result (0-5) took place in 40.74% of cases, "good" (6-10 points) - 40.7 %, "fair" (HAM-D score: >10, but ≤ 50% improvement from baseline) - than 14.8%, "poor" (HAM-D score: >10, but ≤ 50% reduction from baseline) - 3.7%. In the second group "very good" result is revealed in 30.3%, "good" - 42.42%, "fair" - 12.12%, "poor" - 6.06%. Thus, at treatment of combination therapy by sertraline and amisulpride improvement of depressive semiology comes faster, results are leveled by third week of therapy and kept further. However at therapy by fluoxetine and olanzapine combination statistically significant more cases with "very good" and "good" results.

THE LANGUAGE OF SKIN - CASE STUDY OF PSYCHOGENIC PRURITUS

INSTITUTIONS
1. Magalhães Lemos Hospital, Portugal
2. Santo António Hospital, Dermatology Department, Portugal
3. Santo António Hospital, Liaison Psychiatry, Portugal

AUTHORS
1. Isabel Santos Rocha, Dr., mroca@sapo.pt
2. Alexandra Cavaliheiro, Dr., dexterhard@yahoo.com
3. Maria Del Rosário Santos, Dr., mroca@sapo.pt
4. Alice Lopes, Dr.

Objectives: On purpose of 2 clinical reports, the author’s propose a review about Psychogenic Pruritus and its classification in DSM-IV-TR and ICD-10.

Methods: A database review was made using a Medline and PubMed, from 1997 to 2007.

Results: Pruritus is a very frequent symptom in dermatologic patients, but its pathophysiology is not yet completely understood. For the physician, recognising the aetiology of the symptoms plays an important role, especially in mental field. Mental factors appear either as a precipitant or co-morbid to pruritus. We consider that there is much to know about its function as a language mechanism. In histamine induced pruritus, a psychological trauma can lower the baseline perception of pruritus, worsen its intensity and prolong its duration. Its interaction with the mental sphere is quite interesting, and proved to be pronounced in individuals with low coping capacity in face to stress, and in patients with depression. This interaction is due to the stimulation of the CRH, with rising of the opioid mechanisms in the cerebral field. We also remind the important role of Substance P, responding to stress. A psychopharmacological intervention can be made (Doxepin; ISRS’s (Fluoxetine, Paroxetine and Sertraline); Anxiolytic (Alprazolam and Buspirone) and Ondansetron. Moreover its treatment encloses behavioural therapy (namely “habit reversal training”). Relaxation techniques, Hypnosis and Biofeedback techniques.

Conclusion: We propose doctors to study the existence of psychological problems in patients with pruritus, to ensure them a more structured approach including a psychopharmacological and psychotherapeutic treatment.

Major depressive disorder (MDD) is the second cause of incapacity in Latin-America. A brief version would be as useful as the original but also easier and faster to apply.

Objective: To establish the validity of a Brief and Ultra-short Center for Epidemiological Studies Depression (CES-D) Scale in adolescents.

Methods: A representative sampling of 390 students adolescent from Colombia were evaluated both with CES-D and with the semi-structure clinical interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition. The ten items and the three items with the highest correlation with total score were selected to construct Brief scale and Ultra-short scale respectively, and construct validity, criterion validity and internal consistency was analyzed.

Results: The mean age was 14.8 ± 1.22 years old. The MDD prevalence was 11.5%. For the Brief CES-D Scale the Cronbach’s alpha was 0.86. The area under ROC curve was 0.831, with a sensitivity of 77.8%; specificity 74.1%; positive predictive value 28.5%, negative predictive value 96.2%. Two main factors were identified explaining the 55.81% of variance. For the Ultra-short Scale The Cronbach’s alpha was 0.76. The area under ROC curve was 0.802, with a sensitivity of 75.36%; specificity 70.67%; positive predictive value 25.37%, negative predictive value 95.63%. One main factor were identified explaining the 68.19% of variance.

Conclusion: The Brief and Ultra-Short CES-D Scale are good for the screening of MDD in adolescents; moreover, there are no statistical differences between the Original, Brief and Ultra-short CES-D Scale.

Aim: To examine the relationship between duration of a continuous therapeutic response and risk of relapse for the treatment of adults with generalized anxiety disorder (GAD).

Methods: Following 26-week open-label treatment with duloxetine 60-120 mg/day, patients with DSM-IV-TR-defined GAD who met treatment response criteria (Hamilton Anxiety Rating Scale total score reduction of ≥50% to ≤11 and ratings of “much” or “very much improved” at last 2 visits of open-label phase) were then randomized to duloxetine or placebo for 26-week double-blind continuation treatment. Relapse was defined by an increase in GAD illness severity rating ≥ moderate or discontinuation due to loss of efficacy. Time to relapse between treatments was compared using log-rank test for subgroups of patients who had met treatment response criteria continuously for 6, 10, and 14 weeks prior to randomization.

Results: Overall relapse rate was 44.5% for the placebo group (N=211) and 15.0% for the duloxetine group (N=213). Rate of relapse for placebo-treated patients ranged from 45.2% for the 6-week continuous responders (n=188) to 46.8% for the 14-week continuous responders (n=148). Among duloxetine-treated patients, rate of relapse ranged from 15.2% for the 6-week continuous responders (n=184) to 12.8% for the 14-week continuous responders (n=148). Time to relapse was significantly shorter for placebo-treated patients compared with duloxetine-treated patients within each continuous responder subgroup as well as for the overall sample (P< .001 all comparisons).

Conclusion: Duration of therapeutic response prior to randomization of withdrawal did not affect risk of relapse, suggesting benefit from continued long-term duloxetine treatment for GAD.

Aims: To provide an overview of the severity and response to treatment of painful physical symptoms associated with generalized anxiety disorder (GAD) from 3 independent duloxetine clinical trials.

Methods: All studies were conducted with adult outpatients with DSM-IV-defined GAD. Studies 1 and 2 were 9-10 week, placebo-controlled, double-blind studies of duloxetine (60 or 120 mg/day and 60-120 mg/day, respectively). Study 3 consisted of 6-month open-label duloxetine 60-120 mg/day treatment; responders were then randomized to duloxetine or placebo for 6-month double-blind continuation treatment. In each study, patients completed 6 Visual Analogue Scales (VAS) for degree (0-100) of overall pain, headache, back pain, shoulder pain, interference with daily activities, and time in pain while awake.

Results: In the overall pooled sample (N=1727), baseline Vas median scores were 28 for overall pain, 19 for headache, 20 for back pain, 15 for shoulder pain, 18 for interference with daily activity, and 31 for time in pain while awake. Combining data from Studies 1 and 2, duloxetine-treated patients (n=465) showed significantly more improvement on all Vas pain scores compared with placebo-treated patients (n=315, p≤.01 to ≤ .001). In Study 3, during open-label treatment, patients (n=739) reported improvement from baseline for each pain item (each p≤ .001); however, pain symptoms worsened during the double-blind continuation phase for patients switched to placebo (n=190) compared with those maintained with duloxetine (n=202, P≤ .05 to ≤ .001).

Conclusion: Painful physical symptoms occur within GAD, and they improve with both acute and long-term treatment with duloxetine.

Descriptive investigation done in teenage patients who were received and attended in the Suicidal Area of the Lorenzo Ponce Hospital of Guayaquil, Ecuador between 01.07.03 and 31.12.07

Objectives: 1. To analyze the effectiveness on the use of Mirtazapina, on a dosage of 1.5 mg and 30 mg per day after 8 and 12 weeks of application on depressive teenagers with suicidal tendencies. 2. To analyze the incidence and severances on the secondary effects on the use of the Mirtazapina in this group of patients. 3. To determine the daily doses of Mirtazapina effective enough according to the subtype of depression presented by these teenagers.

Materials and Methodology:
1. 276 Medical records of depressive suicidal teenage patients who received Mirtazapina as monotherapy
2. Hamilton Depression Rating Scale (HDRS)
3. Scale for Suicide Ideation (SSI)
4. Clinical Global Impression (CGI)
5. SPSS 10.0
6. Multiple Statistical study, Independence of Variables Hypothesis test and Homogeneity Analysis.

Results
1. After 8 weeks, 56.6 % of the patients with 15 mg of Mirtazapina per day, and 94,11% of the patients who received 30 mg per day, had greatly improved (HDRS)
2. The weight increase in the patients was minimal
3. There was no increase in sleeping hours
4. The dosage of 15 mg of Mirtazapina was effective for moderate and light depression by these patients.

Conclusion The use of the Mirtazapina in depressive teenagers with suicidal tendencies came out effective for the different types of depression, showing very few or almost none side effects.

Theoretical and Conceptual work on infanto-juvenile suicidal conducts and descriptive research done on infanto-juvenile patients of the Suicidology Area of the “Lorenzo Ponce” Psychiatric Hospital of Guayaquil - Ecuador.

OBJECTIVES:
1. Determine the effectiveness of the ecological program of intervention of the Infanto-Juvenile Suicidology Area in patients who display any form of suicide conception who consulted for the first time at the “Lorenzo Ponce” Psychiatric Hospital of Guayaquil-Ecuador between the 01.07.03 and 31.12.07.
2. To determine the etiologic factors of this suicide conception and the most frequent psychiatric pathologies in this age group.
3. To determine the past pathologic history of relatives of this group.

MATERIALS
1. 276 Clinical charts of infanto-juvenile patients who consulted between 01.07.03 and 31.12.07
2. Variable codification table

METHODOLOGY
1. Univariate, multivariate and hypothesis confirmation statistical study.
2. SPSS 10.0

RESULTS
1. Physical and verbal intra-familiar abuse is the most frequent cause for suicidal conception in the group of studied patients.
2. Most of the investigated patients presented/displayed more than a suicidal attempt in its history.
3. The most frequent past pathologic history of parents found in this population was Substance Dependency Disorder.
4. 117 of the 276 patients remarkably improved their individual psychiatric conditions after 8 weeks in the treatment program.

CONCLUSIONS: The ecological program of Suicidology has demonstrated an effectiveness in its four years lifetime since it concerned all the ecosystemic interrelation contexts.

3. José Queirós², Dr, MD

There have been increasing reports of Mania associated with administration of antibiotics. Some authors elected to name this syndrome “Antibiomania”. Antimicrobial-induced mania is a rare but important side effect of antibiotics and it is frequently under-recognized. Reviewing this topic, including published and anecdotal reports the authors acknowledge that clarithromycin and ciprofloxacin are the most frequently associated with the development of mania. The mechanism by which antimicrobials induce mania is still unknown, thus it is considered to be idiosyncratic in nature. Based on a case report, the authors review the mechanisms and the management of antimicrobial-induced mania. A female patient, 18 years old, with no previous history of mental illness or substance abuse, was admitted for psychiatric evaluation with elevated mood, extremely talkative, agitated, with the subjective sensation of increased energy and with flight of ideas and delusions. There was a clear relationship between the onset of psychiatric symptoms and clarithromycin treatment and initial signs of gradual recovery when the antibiotic was discontinued. The clinical remission was obtained after treatment with anti-psychotic and mood stabilizer, both discontinued during the follow up. The authors argue that a new onset of mania in adult patients without psychiatric history should prompt a clinician to search for reversible causes. Further research is needed to determine the incidence of antibiomania, the relative risk factors and the incidence of patients who continue to have persistent affective disorders after the initial episode of mania.

AUTHORS
1. Seda Sahin1
2. Ilker Ozylidirim1
3. Sibel Cakir1
4. Olcay Yazici1

OBJECTIVES: The postpartum period is an exceptionally high-risk time for recurrence of depression or mania for women with bipolar disorder. This study investigated the risk of recurrence of mood episodes among women with a history of bipolar disorder who continued or discontinued treatment with mood stabilizers during pregnancy and postpartum period.

METHODS: These case series comprised 13 women meeting the DSM IV-TR criteria for bipolar disorder, who became pregnant in our observation and therapy.

RESULTS: Nine (69.2%) of 13 patients were found to discontinue any medications, two (15.3%) patients to continue antipsychotic therapy and other two (15.3%) patients to continue carbamazepine. Only one (7.6%) patient had mixed episode during pregnancy but nine (69.2%) patients were found to have depressive, manic or mixed episodes in postpartum period.

CONCLUSION: Although some reports show that pregnancy carries a high risk, our results support that pregnancy is safe in women with bipolar disorder in terms of morbidity. However, the risk of recurrence of episodes in postpartum period is significant.

Introduction: Sertraline is an antidepressant used in the treatment of depression. Our investigation is comparative study efficacy of Sertraline in both psychotic and nonpsychotic depressed patients.

Methods: In our study we analysed 78 patients treated with Sertraline within a 12 week period on the Clinic of Psychiatry. For diagnostic criteria we used MKB10 and Hamilton Rating Scale that was repeated in two week period. The patients were divided in two groups. N=32 patients with psychotic features and N=36 patients with nonpsychotic depression. Medication dosage was started at 50mg daily raised up to 100mg daily after one week period. If patients had not remitted we raised 50mg every two weeks.

Results: Response rate was significantly higher in nonpsychotic depressive patients 75% than in psychotic depressive patients 42%. Nonpsychotic depressed patients responded earlier than patients with psychotic features.

Conclusion: Response rate in patients with psychotic depression to Sertraline therapy is lower than in nonpsychotic depressed patients. The psychotic features were a predictor of response independent on degree of depression.

AIMS: Heavy episodic drinking (HED) is a common harmful pattern of alcohol consumption. Bearing impulsivity in mind, the goal of this study is to examine the association between bipolar spectrum and HED in the general population.

METHODS: Data were derived from the Sao Paulo Epidemiological Catchment Area Study (N=1,464). 122 bipolar subjects were determined through CIDI 1.1 as DSM-III-R Bipolar Disorder (BD) I, II and -NOS. The latter were subdivided as subsyndromic hypomania (SSH) and manic symptoms (MS). HED was defined as a pattern of 12-month alcohol consumption of ≥ 5 drinks/drinking day for men and ≥ 4 drinks for women. The frequency of HED was calculated and an univariate regression analysis was performed in respect of bipolarity and sociodemographic variables. Final model was achieved by means of multivariate logistic regression, through stepwise backward elimination.

RESULTS: The prevalence of HED varied from 36.5% (BD) to 11% (non-affective controls), with a decreasing gradient throughout the bipolar spectrum. BD was associated with a greater chance of HED (OR 4.4). Among bipolar women, this association was even stronger (OR 16.9). The mere presence of manic symptoms didn’t predict HED. Being younger than 45 was the only significant sociodemographic predictor of HED (OR 2.6). Among men, neither bipolarity nor age reached statistical significance.

CONCLUSIONS: The significant association of HED with BD and SSH may play important implications for health policies and therapeutics. One should pay special attention to heavy drinking women since they have a greater chance of being bipolar.

POSTTRAUMATIC MANIA

INSTITUTIONS
1. Leon’s General Hospital, Psychiatry, León, Spain

AUTHORS
1. José de Santiago Sastre, Mr, MD, asuncionsanchezp@hotmail.com
2. Asunción Sánchez Peña, Mrs, Clinical Psychologist, asuncionsanchezp@hotmail.com

Objective: It is revised the concept of Posttraumatic Mania and it’s analyzed de controversy about if precipitant cause trigger an underlying bipolar disorder or is a pure organic disorder

Methodology: It’s presented one case of posttraumatic mania in a 66 years old man whist neither personal psychiatric history nor familiar genetic predisposition. It is revised bibliographic documentation

Conclusions: it is estimated that about 7% of patients who suffer from a cranioencebral trauma present affective disorder, being less frequent the mania cases which are 10% of the posttraumatic affective disorder. There is little bibliography about this theme and it is based on the description of patients and in small samples. The authors taking into account the current diagnostic manuals DSM IV-R y CIE 10 argue that the evaluated patient observed the criteria of a maniac episode of traumatic etiology

Aim: Findings from clinical and community studies have shown that subjects with a family history of suicidal behavior are at increased risk of both attempting and committing suicide. A family history of suicide has not previously been examined in prisoners.

Methods: A sample of 1,179 prisoners were assessed with a psychiatric interview and psychometric tools through the Brown-Goodwin Assessment for Lifetime History of Aggression (BGLHA), the Barratt Impulsivity Scale (BIS), Buss-Durkee Hostility Inventory (BDHI), and Eysenck Personality Questionnaire (EPQ). Prisoners with a family history of suicide were compared with prisoners without a family history of suicide on clinical and personality variables.

Results: 5.9% of the whole sample had a family history of suicide. Prisoners with a positive family history of suicide had significantly more frequent suicide attempts compared to the other group (36% vs 12%, p< 0.0001); they also had more often a previous history of convictions, a history of juvenile convictions, aggressive behavior in jail. They also scored higher on the scales for aggression (BGLHA), hostility (BDHI) and impulsivity (BIS), and had more frequently neuroticism features of personality on the EPQ.

Conclusion: Consideration of family history of suicide should be used in the assessment of prisoners as indicator of increased risk for suicidal behaviours, and possible issues related to psychopathological traits such as impulsivity and tendency to aggression.

Introduction: Theory of mind (ToM) is the ability to represent one’s own or another’s mental states such as beliefs, intentions, desires, and knowledge. ToM impairments have been associated with clinical symptoms of many psychiatric and neurological disorders, including autism and schizophrenia. The aim of this study was to evaluate ToM abilities of patients with obsessive-compulsive disorder (OCD) and compare their results with healthy controls.

Method: 20 OCD patients and age, sex and education matched 20 healthy controls were compared according to their performances on ToM tasks (first and second order false belief, hinting task and “advanced” Tom tasks such as double-bluffing), Verbal Memory Processes Test, Weschler Memory Test, Stroop Test.

Results: Patients’ performance was worse than healthy controls on all of the ToM tasks, but the results were significant for ToM total (p=0.009) and double-bluff total (p=0.000) scores. For all other neuropsychological tasks, patients’ performances were worse than healthy controls, but the results were significant for Visual Reproduction-immediate recall (p=0.003), Visual Reproduction-delayed recall (p=0.009), Verbal Fluency (p=0.003), Verbal Memory (p=0.033), Stroop 2 (p=0.04) and Stroop 4 (p=0.01). Patients’ performance on ToM tasks was not significantly correlated with clinical features such as illness duration and severity according to YBOCS, as well as different pharmacological treatments (monotherapy/combination), number and class of medications used. No significant correlation was found between performance on ToM tasks and other neuropsychological tasks.

Conclusion: Patients diagnosed with OCD may show significant impairments on advanced ToM abilities and these deficits seem to be independent of general cognitive deficits.

AFFECTIVE DISORDERS IN PATIENT WITH ACUTE MYOCARDIAL INFARCTION

INSTITUTIONS
1. Moscow Research Institute of Psychiatry, Moscow, Russian Federation

AUTHORS
1. Maria Semiglazova¹, Dr, MD, semmary@yandex.ru

Aims: an analysis of specific features of affective disorders and the effectiveness of complex therapy (cardiotropic drugs and anti-depressant (tianeptin) in patients after acute myocardial infarction

Methods: psychopathological (Hamilton Depression Rating Scale, Hamilton Anxiety Rating Scale, Toronto Alexithymia Scale(TAS), Symptom Cheklst-90 -SCL-90, Holms-Rahe scales,) 36-item short-form health survey (SF-36), ECG, exercise stress tolerance during 6-month follow-up study.

Results: 108 subjects after acute myocardial infarction were observed. Affective disorders were found in 44(40.8%). Depressive episode in 29(26.9%) thereof 19 patients were on tianeptine treatment. Adjustment disorders, anxiety disorders, chronic mood disorders were observed in 15(13,9%). The statistical analysis has discovered that group with affective disorders had significantly greater mental stress compare to group without any affective disorders (p=0.002). Patients with affective disorders had significantly lower health quality of life and higher alexithymia level (p=0.002). Patients with depression more often had post infarction angina pectoris (53,6% and 22,2%, p=0,017). A 6 month later angina pectoris were more frequent in group of patients with depression denied an anti-depressant therapy, the number of angina pectoris attack in this group were significantly higher as well as exercise stress tolerance was the lowest (p=0,036).

Conclusion: The presence of affective disorders in patients with acute myocardial infarction is associate with lower health quality of life. The tianeptin treatment not only impact beneficial on depressive syndrome but extend exercise stress tolerance and improve health quality of life. This data may be used for optimization of affective disorders therapy in patients after acute myocardial infarction.

DEPRESSIVE DISORDERS IN PALLIATIVE MEDICINE

INSTITUTIONS
1. Mental Health Research Institute, Russian Federation

AUTHORS
1. Nataliya Shakhurova¹

Objective: One of relevant tasks of palliative care is detection of states of physiological sadness typical for non-curable patients and disorders of depressive spectrum. This is why objective clinical assessment of mental state of patients acquires a special importance.

Methods and Material: Investigation included patients of unit Hospice with cancer pathology of IV clinical group and patients of unit House of nursing care with combined somatic pathology. Depressive disorders in patients of the hospital for palliative care were assessed with Hospital Anxiety and Depression Scale (HADS) and Geriatric Depression Scale (GDS-15). Total number of interviewed has constituted 100 persons, mean age 72,3±3,8 years. Inclusion criteria were as follows: ability to understand text of questionnaires and willingness to fill them. We excluded patients with aphasia, severe cognitive disorders, disturbances of conscience, poor hearing.

Results: According to ICD-10 criteria, depressive disorders have been revealed in 65 % of patients, including organic affective disorder in 32% of patients, recurrent depressive disorder in 16% of patients, dysthymia in 12%, and adjustment disorder in 5% of cases.

Conclusions: Thus, assessment with Psychodiagnostic scales has shown that used questionnaires are sensitive to revealing the disorders of depressive spectrum in these patients. There filling does not require great amount of time and allows obtaining qualitative assessment of severity of depression and anxiety without tiredness of patients. Attention to soul state of the patient improves psychological contact with medical staff, contributes to more comfortable stay in hospital.

Background/objective: Depression is prevalent among the elderly and can have serious negative outcomes in this age group. Researches show that psychotherapy may be beneficial in treating depression in the elderly. One type of psychotherapy is participation of the elderly in reminiscence groups which has proved to be cost-effective and relatively free from harmful effects. The purpose of this study was to assess the effect of group reminiscence on the depression of older adults in Shiraz Jahandidegan Center in Iran.

Material/methods: A quasi-experimental design was conducted, using purposive sampling. Forty-nine elderly participated in the study and were assigned to five groups. The selected elders participated in six group reminiscence sessions that were held twice weekly for a three week period. A comparison was conducted with repeated measures of depression before, immediately after, and one month after the intervention. Geriatric Depression Scale-Short Form (GDS-SF) which consists of 15 items was used as study instrument.

Results: Analysis of data revealed a significant decrease in depression in the elderly subjects after the intervention and one month after the intervention (p < 0.001).

Conclusion: The results of this study showed that group reminiscence is a useful treatment for older people with depression. This intervention can provide a pleasant and supportive environment for the elders to work out challenges posed at this stage of their life cycle.

Obsessive compulsive disorder (OCD) is a common psychiatric disorder amounting to significant losses in personal, financial, social, occupational and family domains. We attempt to quantify this disability, by means of WHO-disability assessment scale, in different severity of OCD. The results, interpretations, and the possible explanation shall be discussed in detail in the presentation.

Background: Few studies address the long-term follow-up of standardized, first line treatments for OCD. This study aimed to investigate the influence of the type of first treatment received (group cognitive behavioral therapy (GCBT) or fluoxetine) on the six-month outcome of OCD.

Methods: Sixty-four patients completed a randomized open trial of GCBT (n=22) or fluoxetine (n=42) for 12 weeks. Non-responders (reduction in YBOCS baseline score lower than 35%) to group CBT received fluoxetine for another 12 weeks (n=13; one patient remained in GCBT), whereas non-responders to fluoxetine (n=30) received additional GCBT (n=2) or augmentation therapy with quetiapine or clomipramine (n=16) or remained on SSRI monotherapy (n=12) for another 12 weeks. Response was assessed by blind raters at weeks 12 and 24. Response rates were compared for the two first-treatment groups using the Mann-Whitney test and the qui-square test.

Results: The average baseline YBOCS score reduction at week 12 was 22.24% for GCBT and 26.67% for fluoxetine (non-significant difference between groups, p-value=0.376). At week 24, 42.8% of non-responders to group CBT who received additional fluoxetine and the only patient who remained on GCBT became responders. Among non-responders to fluoxetine, 10% became responders to SSRl monotherapy, 10% responded to augmentation therapy with clomipramine or quetiapine and 3.3% responded to addition of GCBT. Forty-five percent of the GCBT group and 35.7% of the fluoxetine group were responders after 6 months of treatment (p=0.493).

Discussion: Response rates were lower than those reported in randomized clinical trials, possibly due to the adoption of wide inclusion criteria. Having received GCBT or fluoxetine as the first treatment did not lead to different outcomes after six months. A larger follow-up study exploring the addition of fluoxetine to GCBT, as well as the augmentation of fluoxetine with either clomipramine or quetiapine, is currently underway and should clarify if these are effective alternatives for resistant patients.

ATYPICAL ENDOGENIC DEPRESSIONS: CLINICAL PICTURE, DYNAMICS, THERAPY

INSTITUTIONS
1. Rostov State Medical University, Psychiatry and Narcology, Rostov-on-Don, Russian Federation

AUTHORS
1. Irina Shurkova¹, Dr, 2793665@mail.ru
2. Vladimir Mrykhin⁵, Dr, Phd, 2793665@mail.ru

Examined were 160 atypical endogenic depressive patients (36 males and 124 females) of 35.7±4 years’ mean age. The group comprised 72 patients diagnosed with a depressive episode and 88 patients suffering from recurrent depressive disorder. The typing of 107 patients showed moderately serious depression, while 53 patients depression was mildly serious. Studied were the socio-demographic characteristics, biomedical factors, constitutional predisposition, illness characteristics. The patients were divided into 4 groups of 40. The 1st group was prescribed sertralin, 200 mg as a daily dose; the 2nd group were treated with maprotilin, 200 mg as a daily dose; in groups 3 and 4 similar therapy was combined with 10 daily séances of endonasal infra-red laser radiation. The latter had the following parameters: wavelength - 0.89 microns; pulse capacity - 2.8 Vt; frequency of following of pulses - 3,000 Hz; exposition - 256 sec.

Combined antidepressant + laser therapy appeared more operati. Maprotilin application lead to faster symptomatology reduction, while sertralin caused less negative side-effects. The best therapeutic results were achieved with asthenic-depressive and larva-depressive patients; more therapy-resistant were hypochondriac and depersonalization-derealization disorders. A sooner therapeutic effect could be noted in the first depressive episode patients and low depressive disorder degree patients. The lower the affect strength and the greater the specific weight of the optional symptoms, the less successful the depression therapy. The less the illness duration, the greater the probability of drug resistance formation. The adequacy of treatment of the first depressive episode in many instances defined the further illness stereotype and the forecast.

RESULTS OF CEREBRAL MRI IN ATYPICAL ENDOGENIC DEPRESSIVE PATIENTS

INSTITUTIONS
1. Rostov State Medical University, Psychiatry and Narcology, Rostov-on-Don, Russian Federation

AUTHORS
1. Irina Shurkova1, Dr., 2793665@mail.ru
2. Vladimir Mrykhin1, Dr., PhD, 2793665@mail.ru

Examined were 70 patients (56 females and 14 males) suffering from atypical depressive disorders. Their mean age was 37.6±5. The studied group comprised 23 patients diagnosed with a depressive episode and 47 patients suffering from recurrent depressive disorder. 44 patients' typing showed moderately serious depression, and in 26 patients depression was mildly serious. In 59 patients (49 females and 10 males) revealed were pathological changes manifested as expanded lateral and 3rd ventricles, reduced frontal, orbital frontal, medial prefrontal, temporal and bregmatic cortex areas, ventral striatum, as well as gray and white matter of the hippocampus.

Evident reduction of the hippocampus volume in depressive patients (as compared to the group of sane probationers) after the first depressive episode reaches 10% for the gray matter and up to 25% for the white matter. The above cerebral changes were more frequent and frank in senior patients, who long suffered from the disease, in the patients with a large number of depressive phases in anamnesis, in the patients with chronic drug resistance, and in the patients with depersonalization-derealization and hypochondriac depressive disorders.

CHARACTERIZATION OF DEPRESSION COMORBID TO PTSD

INSTITUTIONS
1. Clinical Center, Clinic for Mental Health, Nis, Serbia and Montenegro

AUTHORS
1. Maja M Simonovic1, Mrs, MD, caslav.stefanovic@gmail.com
2. Grozdaniko B Grbesa1, Mr, PhD, grbesa@eunet.yu
3. Tatjana M Milenkovic1, Mrs, MD, minat@aunet.yu

Aim: The aim of the paper is to determine the severity of depression which is comorbid to posttraumatic stress disorder and to determine the group of symptoms which are most prominent in depression comorbid to posttraumatic stress disorder (PTSD).

Method: 60 patients were assessed in the experimental and in control group using SCID for DSM-IV. The presence and the severity of the disorders were assessed by means of the following instruments: Clinician-Administered PTSD Scale for DSM-IV, Montgomery-Asberg Depression Rating Scale and Hamilton Rating Scale for Depression. Differences between groups were evaluated using T-test and by means of the correlation analysis of the data.

Results: showed that depression which is comorbid to PTSD is of significant clinical severity. The group of symptoms: lassitude, inability to feel (p<0.001), suicidal thoughts (p<0.01) and inner tension (p<0.05) contributes mostly to the global severity of the depression which is comorbid to PTSD on MADRS instrument. The group of the symptoms: suicide and gastrointestinal symptoms (p<0.001), guilt, hypochondriasis, work and activity, anxiety psychic, agitation (p<0.01), and weight loss, genital symptoms and anxiety somatic (0.05) contributes mostly to the global severity of depression which is comorbid to PTSD on HAMD instrument.

Conclusion: Symptoms on MADRS instrument describe the nature of this type of depression. Symptoms of HAMD instrument indicate the development of the more severe forms of the disorder. Those results shed some light to the different patterns of brain activation related to comorbid depression occurring in the context of PTSD.

SEASONAL AFFECTIVE DISORDER IN SCHOOLCHILDREN

INSTITUTIONS
1. Mental Health Research Institute, Affective States Department, Tomsk, Russian Federation

AUTHORS
1. G. G. Simutkin¹, Dr., MD, niipz@sibmail.com
2. N. M. Popova¹, Mrs., niipz@sibmail.com

Objective: To study specific weight of seasonal affective disorders (SAD) and subsyndromal SAD (sub-SAD) in schoolchildren. Materials and methods: 242 schoolchildren (88 boys and 154 girls) of Tomsk (West Siberia) at the age 15.2 ± 1.5 years have been examined. As a tool of examination SPAQ-CA (Seasonal Pattern Assessment Questionnaire for Children and Adolescents) (Swedo S.E. et al., 1995) was used.

Results: In the course of screening examination of schoolchildren incidence of SAD has constituted 6.6% (n = 16 - 9 girls and 7 boys). Part of interviewed schoolchildren met criteria for sub-SAD (7.4% - 10 girls and 8 boys). Most frequently as the first month when schoolchildren felt “less energy” January was indicated (18.6%), were “more irritable” - March (11.6%), felt “worst” - January (11.6%). In 35.5% of cases (23 boys and 63 girls) examined schoolchildren rated seasonal fluctuations of their way they felt as a problem. Mood as the most changeable for a year characteristic closely correlated with seasonal changes of level of energy, irritability, school problems, sleep and appetite.

Conclusions: Seasonal cyclicity in mood, general activity, and behavior and school progress in schoolchildren can be associated with photoperiodic mechanisms; detection of this seasonal cyclicity can be useful for early diagnosis and prevention of SAD in child-adolescent age; in indicated cases positive influence of bright-light therapy is possible.

AN OPEN STUDY OF LOW FREQUENCY TRANSCRANIAL MAGNETIC STIMULATION FOR TREATMENT RESISTANT BIPOLAR DEPRESSION

INSTITUTIONS
1. Stanford University, Psychiatry, Stanford, AC, United States

AUTHORS
1. Hugh B Solvason¹, Dr, PhD MD, solvason@stanford.edu
2. Cecilia Nowakowska¹, Dr, MD
3. Rowena Gonzales¹, Dr, PHD
4. Maor Katz¹, Dr, MD
5. Jessica Hawkins¹, Ms, jhawk@stanford.edu
6. Charles Debattista¹, Dr, MD

Aims/Objectives: Bipolar disorder is characterized by periods of elevated mood and depression. Most of the time ill is spent in the depressive phase and therefore associated with the greatest disability and mortality. This study examined the efficacy of low frequency repetitive transcranial magnetic stimulation (rTMS) in an open trial of 28 subjects with treatment resistant bipolar depression.

Methods: Low frequency TMS was delivered 5 days a week for 4 weeks, over an approximation of the right dorsolateral prefrontal cortex based on external landmarks. The rTMS was performed at 1Hz, and set at 110% of the motor threshold, determined by direct stimulation of the right motor cortex in the area that induced movement in the left abductor pollicis brevis. Subjects were assessed at the end of week 1, 2, 3 and 4 with Hamilton Depression Rating Scale (HDRS), the Beck Depression Inventory (BDI), and the Clinical Global Improvement-severity (CGI-s) score.

Results: The average length of the current depressive episode was 2.7 years, with 14.6 prior medication failures. Fourteen of 26 had had ECT in the past. Baseline and end of week 4 (EOW4) scores were: HDRS 23.76 and 14.04 respectively; BDI 30.56 and 20.04 respectively; CGI-s 4.96, and 4.22; all of which were statistically significant improvements.

Conclusions: Given the clear marked treatment resistance of these subjects recruited for this study, these findings suggest that low frequency rTMS over the right dorsolateral prefrontal cortex may improve clinical symptoms over 4 weeks in subjects with depression that has failed aggressive pharmacotherapy treatment.

Aim: The study's aim was the comparison of efficacy and tolerance of the OCD patients treated with Sertraline toward those treated with Clomipramine.

Method: The study was focused on the inpatients and outpatients presented at Psychiatric Clinic, diagnosed with OCD during September 2005-March 2006. The criteria of being selected were randomization of those with > 20 points according to Yale-Brown Obsessive Compulsive Scale and > 4 points according to Clinical Global Impression Scale. There were two groups: first group was treated with clomipramine and the second with sertraline. Sertraline doses were 50 and 200 mg/day and clomipramine 100, 125 and 150 mg/day. The study was conducted during a period of 12 weeks including tree evaluations through YBOC scale and CGI.

Results: 91.8% of the patients completed the study. 18 were treated with sertraline and 16 with Clomipramine. Both treatments resulted with the same efficacy in treating the OCD symptoms. The patients treated with sertraline reported less side effects frequency and intensity and more tolerance than the patients treated with clomipramine.

Conclusions: Both treatments showed therapeutic efficacy in treating the OCD symptoms. Clomipramine caused more side effects and the number of patients dismissed from the study was higher in the group of clomipramine. Sertraline is as effective as clomipramine for treating the OCD but has more compliance and less side effects.

5. Jung Bum Kim⁴, Dr., MD,PhD

Objective: This study evaluated heavy metals and minerals with hair analysis, also evaluated severity of depressive symptoms. And we examined cross-sectional associations between heavy metals, minerals and depressive symptoms, severities, onset age and symptom duration.

Method: Subjects were 62 patients that were diagnosed as depressive disorder, including major depressive disorder, dysthymic disorder and depressive disorder NOS. Heavy metals and minerals were examined through hair analysis with patient's scalp hair in occipital area. Inductively coupled plasma-mass spectrometry (ICP-MS) was used in hair analysis. We measured 10 heavy metals, including Hg, Pb, Al, Ba, etc. and 16 minerals, including Na, K, Ca, Mg, Zn, S, P, Cr, Mn, Co, Fe, Cu, Se, Li, V, Mo. And also, we calculated several ratio, for example Zn/Cu, Zn/Mo, Zn/Pb etc.. Demographic data was collected from interview and depressive symptoms were evaluated with Beck depression inventory-II (BDI-II), Hamilton depression rating scale (HDRS), SCL-90-R, Hamilton anxiety rating scale.

Results: Depressive patients showed significant low level in some minerals, such as Zn, Cu, Mo (p<0.05). And also, differences among each depressive disorder were existed in Na/K and Zn/Cu. But, No difference were observed between groups, in terms of symptom severity, duration and onset age.

Conclusion: This study suggests that low level of some trace elements may be related to depression. But, it is unclear that these findings may contribute to onset or result of depression. Anyway, analysis of trace element may be useful method in evaluation of depressive patients. And, dietary supplement of diminished elements may be helpful to treatment of depression.

5. Antoni Florkowski¹, Mr., MD

Introduction: The problem of suicides, because of its social aspect, is the source of numerous researches. Suicidal attempts are more frequent in the group of patients hospitalized due to psychiatric disorders, while affective and personality disorders predispose to committing suicide attempts. In Poland, a male aged approximately 45, living in a village or small town, unemployed or working as a farmer or worker, committing suicide by hanging himself, is a typical suicide 4 to 5 times more often. Women more often commit unsuccessful suicide attempts using less drastic methods. An accurate analysis of the etiopathogenesis of suicides will allow to treat and prevent suicidal attempts more effectively.

Objective: The authors tried to established a sociodemographic profile of patients hospitalized in psychiatric hospitals who committed suicidal attempts; to establish the most frequent reasons and methods of committed suicidal attempts and to evaluate the general level of aggression and autoaggression in the studied group.

Material and methods: The patients hospitalized in the J. Babinski Memorial Hospital in Lodz were enrolled in the study. The following methods were used: sociodemographic and medical (developed by the authors) surveys, Kelley’s inventory, Moos’s test, SCID-II, and the Inventory Psychological Aggression Syndrome (IPSA II).

Results: The majority of enrolled patients were males. The examined patients achieved high results in all aggression inventories, particularly in autoaggression and hostility towards themselves. 90% of the studied patients had personality disorders. Their inability to cope with stress effectively was also established. Detailed results will be presented in the publication.

DEMENTIA AND SUICIDAL ATTEMPTS: DISCUSSION REGARDING DLB AND FTD CASES

INSTITUTIONS
1. Gifu University Graduate School of Medicine, Psychopathology, Gifu, Japan

AUTHORS
1. Tomoji Takata¹, Mr., MD, PhD, takatomo@gifu-u.ac.jp
2. Ken Takaoka¹, Mr., MD, PhD, takaoka@gifu-u.ac.jp

Aims: In Japan more than thirty thousand people have committed suicide every year since 1998. One third of them are elderly people’s cases. However, there are no case studies that include detailed description of attempted suicides with dementia.

Methods: Descriptive, psychopathological case studies of dementia. To protect the patients’ anonymity, their details of life history are eliminated.

Results:
Case 1. A 75-year-old woman exhibited a delusional state and entered hospital. Her essential features were disturbed consciousness, auto-sosie and visual hallucination. One month after the hospitalization, she attempted suicide. She was diagnosed to have a dementia with Levy body (DLB) as a result of clinical examinations. Her behavior was considered to be due to the slightly altered consciousness.

Case 2. A 71-year-old woman, who had previously suffered from cerebral infarction, began to apologize to her husband for no rational reasons. Her apologies were stereotyped and accompanied by no mood swings. A week after the journey with her family members to the famous scenic spot, named Toujinbo, she committed suicide at a nearby river. Toujinbo is known as the place where many people drown themselves in a sea. After her admission, she was diagnosed to have a fronto-temporal dementia (FTD). Her behavior was considered to be due to simplism without mood-congruent thinking.

Discussion and Conclusion: Suicidal attempts of two patients are caused by not major depression, but the psychopathology of DLB/FTD. Psychiatrists should take account of the psychopathology of dementia to provide appropriate precautions against suicides.

Objectives: Psychomotor disturbances in depressive patients are bidirectional - toward retardation or agitation. They are usually assessed by means of clinical observation. In order to introduce more objectivity in recording and measuring psychomotor activity, we have applied a new approach using an internationally patented motion analysis system (1). The aim of the present study was to compare the proportions of psychomotor retardation or agitation in relation to bipolar or unipolar depression.

Methods: 30 patients - 15 with bipolar and 15 with unipolar depression and 30 healthy controls were examined by means of computerized ultrasound cranio-corpo-graphy (CCG) for objective quantification of psychomotor activity. A standard clinical assessment was also performed. The severity of depression was evaluated by Montgomery-Asberg Depression Rating Scale and that of anxiety - by Hamilton Rating Scale for Anxiety. Patients were additionally divided into two subgroups - with inhibited or disinhibited CCG-patterns respectively, according to their velocity and spatial CCG-parameters.

Results: Both bipolar and unipolar depressive subgroups showed comparable clinical signs of psychomotor retardation or agitation but the majority of the bipolar subgroup exhibited mania-like CCG-disinhibition, being related to higher anxiety scores. Many bipolar patients presenting clinically with psychomotor inhibition, in fact showed CCG-disinhibition. This finding suggests that dissociation exists between clinical assessment and CCG-recording, the latter being more informative for the subjective state of the patient.

Conclusion: Some of the bipolar depressive patients presenting clinically as retarded are in fact anxious and mentally disinhibited.

4. Boon Hock Chia, Dr, MD

OBJECTIVE. Few studies were done that look at the risk factors for suicide for patients with schizophrenia in Asia. The aim of this study was to identify such factors in a sample of patients from the Institute of Mental Health in Singapore. The nature of their inpatient and outpatient treatment were also explored.

METHOD. This is a case-control study of 57 patients with schizophrenia who committed suicide from 2003-2004. Controls were 57 surviving patients with schizophrenia who were individually matched for age, gender and period of treatment.

RESULTS. Suicide was significantly associated with history of attempted suicide using lethal and non-lethal means, delusions (mainly persecutory), involuntary hospitalisation, defaulting treatment and side-effects (mainly extra-pyramidal side-effects) to medication. Periods soon after discharge and after an outpatient consult were identified as high risk periods. One finding is that few patients with schizophrenia expressed suicidal ideas to healthcare workers prior to suicide. Stepwise conditional logistic regression showed that the factor that best predicted suicide in schizophrenia was history of attempted suicide using lethal methods (adjusted relative risk of 65).

CONCLUSIONS: Singaporean patients with schizophrenia share some common risk factors for suicide identified in Western studies but the lower prevalence of substance abuse and comorbidity in Singaporean cases was one notable difference. Side-effects and default of treatment continues to be a common problem when treating individuals with schizophrenia. Abnormal or inhibited expression of suicidal ideation in schizophrenia patients may account for such warning signs not picked up prior to suicide.

BACKGROUND: Self-mutilation behaviors can occur in various psychiatric disorders, but reports of self-mutilation in obsessive-compulsive disorder (OCD), particularly self-inflicted eye injuries, are very rare in the literature (1).

METHOD: The case of a 41 year-old single OCD patient who became almost blind due to compulsive manipulation of his ocular cavities is reported.

RESULTS: The patient presented cleaning and ordering/symmetry rituals since he was 12 years-old and, 17 years later, he began to present persistent doubts regarding the shape of his ocular cavities, associated with a repetitive urge to touch them in order to check the exact format of the bones and cartilages. He developed glaucoma in the left eye that lead to impairment in his optic nerve and complete visual acuity loss. In his right eye, the cornea was injured, also leading to important loss in visual acuity. Differential diagnosis with tic disorders is discussed and the patient’s treatment approach at the University’s outpatient clinic over three months is also described.

CONCLUSIONS: Although rare, severe and irreversible clinical complications like this can occur in OCD and may considerably worsen the individual’s quality of life, also affecting family members. This report contributes to the important, but neglected discussion concerning severe self-mutilation behaviors in OCD, which may even characterize a specific subtype of this highly heterogeneous condition (2).

Objective: To evaluate possible gender-related differences in obsessive-compulsive disorder (OCD) clinical features in a large sample of Brazilian patients, because previous studies have shown differences in phenotypic expression between men and women, including mean age at onset of obsessive-compulsive symptoms (OCS), types of OCS, comorbid disorders, clinical course and prognosis.

Method: Three hundred and thirty OCD patients (DSM-IV criteria) assisted at three public Universities and at two private practice clinics were evaluated. The instruments used were: the Yale-Brown Obsessive-Compulsive Scale, the Beck Depression Inventory, the Yale Global Tics Severity Scale and the Structured Clinical Interview for DSM-IV Axis I Disorders (to assess psychiatric comorbidity).

Results: Fifty-five percent of the patients (n=182) were men, which were significantly more likely than women to present sexual, religious and symmetry obsessions, and mental rituals, as well as early onset of OCS. They also presented more comorbid tic disorders and post-traumatic stress disorder compared to women, and a tendency to present more social phobia and lower income levels. Besides showing a significantly higher mean score in the Beck Depression Inventory, women were more likely to present comorbid simple phobias, eating disorders in general (anorexia in particular), impulse control disorders in general, compulsive buying and skin picking in particular. There were no significant differences between genders concerning OCD global severity, neither in the obsession or compulsion subscales.

Conclusion: The present study confirms some gender-related differences described in other cultures and countries, which may have important implications for studies of OCD etiology and treatment.

Objective: About 80% of all psychiatric disorder diagnosed in the US population involved comorbid disorders and the most frequent are anxiety and mood disorders, and substance abuse. The aim of this study was to investigate the pattern of comorbidity among major depression patients.

Methods: The levels of anxiety, presence of chronic somatic illness or substance abuse, suicidal behaviour, cognitive impairment were evaluated among 50 patients with major depression. The levels of anxiety were evaluated using STAI, levels of depression with HAMD, cognitive impairment using Benton neurocognitive test.

Results: Major depression, chronic somatic illness and substance abuse were significantly more prevalent in major depression patients with high anxiety levels comparing with respondents with no anxiety increased levels. No significant relationship was observed between higher anxiety levels and cognitive impairment.

Conclusions: Major depression is often accompanied with other psychiatric disorders or symptoms. These association may result with social and occupational impairment, poorer response and higher risk of complications, such as suicidal behaviour.

AIMS: The aim of this study is to evaluate the incidence of depression among nurses in the stressful environment of the Psychiatric Hospital of Attica.

METHODS: In a study concerning the psychological status of psychiatric female nurses, 100 questionnaires were anonymously administered in December 2007. The questionnaire used was the Beck Depression Inventory II (BDI II).

RESULTS: From a group of 100 nurses, 43% were aged below 35, 35% were aged 35-45 and 22% were aged over 45. In the “below 35” age group, 46.5% scored normal, 18.6% scored for mild depression, 7% scored for moderate depression, while 46.5% scored “fake good”. In the “35-45” age group, 31.4% scored normal, 31.8% scored for mild depression, 18.2% scored for moderate depression, while 18.2% scored “fake good”. Psychiatric nurses younger than 35 score statistically significantly lower on BDI than 35-45 and over 45 year old nurses. Younger nurses also exhibited a significantly higher percentage of fake good scores.

CONCLUSION: Psychiatric nurses over 35 appear to exhibit a greater extent of work burden compared to the younger nurses’ group, as measured by their BDI depression scores. The older nurses’ increased frankness in questionnaire completion might indicate greater need to communicate their distress and greater trust towards their medical colleagues.

4. Annette Lam, Ms., MS, 5. Zhongyun Zhao, Dr., PhD

Objective: To examine incidence of suicidal ideation, violent behavior, and deliberate self-harm after switching to risperidone long-acting injection (RLAI) in patients with schizophrenia enrolled in the electronic-schizophrenia Treatment Adherence Registry (e-STAR) from Czech Republic and Slovakia.

Methods: e-STAR is an international, long-term, prospective, observational study of patients with schizophrenia who commence RLAI treatment. Data are collected both retrospectively for 1 year and prospectively every 3 months for 2 years. The treating physician evaluated whether there was a presence of suicidal ideation, violent behavior, and self-injury at baseline and prospectively at 3 monthly intervals. Pooled results presented are based on data from patients who have completed their 18-month follow-up visit.

Results: To date, total of 1324 patients have been enrolled in e-STAR from the Czech Republic and Slovakia; 296 patients with at least 18-months of data available (97.3% still on RLAI) were included in this analysis. Of the 296 patients, 53.7% were male with a mean age of 37.6±12.1 years and a mean time since diagnosis of 9.6±9.0 years. Compared to baseline, significant reductions were observed in the occurrence of suicidal ideation (21.0% to 0.0%, p<0.001), violent behavior (16.5% to 0.3%, p<0.001), and self-injury (8.2% to 0.3%, p<0.001).

Conclusions: This 18-month interim analysis of open-label observational data suggests that incidence of suicidal ideation, violent behavior, and self-injury was significantly reduced from baseline in patients with schizophrenia treated with risperidone long-acting injection.

Studies have showed that cognitive-behavior therapy (CBT) is the most effective treatment for children with anxiety disorders. However, a significant proportion of them do not respond or show only partial response. Prevention has been suggested as an effective way of reducing anxiety problems in children. However, very few study have examined its efficacy.

Objective: The objective of this study was to examine the efficacy of a CBT prevention program of anxiety disorders in young children (4-7 years old) that focus on parental psychopathology and parental behaviors.

Method: Parents were recruited from a sample of 50 parents. They completed a battery of questionnaires and took part to an interaction task with their child. The parents were selected by the Anxiety Disorders Interview Schedule. The program has the following objectives: help the parents coping with their own anxiety, develop a positive parent-child relationship, help the parents using efficient educative practices (especially those related to the anxious behaviors of their child), and to decrease avoidance behaviors of the children. The intervention was conducted in groups of 5 parents and lasted 8 weeks. Immediately after the program, the parents completed the same measures.

Results: Preliminary results from a small sample of parents that completed the follow-up (N = 8) showed changes in their own level of anxiety and significant changes in their parental behaviors, especially a decrease of over control and overprotection. But no changes were observed on the child anxiety.

Conclusion: Complete results will be presented and discussed with future directions suggested.

Anxiety disorders are among the most frequent psychiatric conditions in children and adolescents, with prevalence rates from 10 to 22%. The first part of this presentation will focus on empirically-based treatments, such as cognitive-behavioral therapy (CBT) and pharmacotherapy.

Objective: This study was designed to test the efficacy of a family-based treatment of childhood anxiety.

Method: After screening 2667 children in schools, 148 families were administered a series of questionnaires measuring anxiety, depression, parental attitudes, parental psychopathology, etc. From this sample, 84 families were selected and assigned to a family-based treatment or to a control group. The comparison group did not receive the intervention but could receive treatment in the community. The families were French-speaking, mainly single-parent families, from middle-class suburbs. The program consisted of 10 weekly two-hour sessions, in a group format of 5 to 8 families. Interventions with children included cognitive-behavioral strategies for coping with anxiety such as exposure, cognitive restructuring and relaxation. The parent sessions taught parents how to help their children cope with anxiety, how to cope with their own anxiety, and how to develop more effective parental skills.

Results: Results showed a decrease of anxiety, depression and externalizing symptoms in children of the intervention condition, as well as changes in parental behaviors such as overprotection. The 5 year follow-up indicated that parental behaviors such as overprotection have continued to decrease in the treatment group.

Conclusion: The discussion will examine some future directions in the treatment of anxiety disorders in children and adolescents.

Introduction: Repetitive transcranial magnetic stimulation (rTMS) is quite a new biological method for treatment of patients with depressive disorder. According to some studies rTMS could improve cognitive functions in these patients too, but our knowledge in this area is still insufficient.

Aim: The aim of this simple blind randomised study is to assess the ability of high-frequency rTMS to improve psychopathology and cognitive functions in patients with depressive disorder.

Methods: Forty male patients with depressive disorder were divided into two subgroups. One subgroup was treated with rTMS and the other subgroup with antidepressants of the third or fourth generation. rTMS was applied to the left dorsolateral prefrontal cortex. The stimulation frequency was 15 Hz and the stimulation intensity was 110% of the motor threshold. Each patient received 15 rTMS sessions and each session consisted of 1500 stimuli. The psychopathology was rated by HAMD-21 and MADRS and each patient underwent complete neuropsychological examination (consisting of Raven’s Progressive Matrices, TMT, CPT, CWT, testing of visual and auditory reaction times, WCST, VFT, WMS-III) before and after the treatment.

Results: Fourteen patients were responders (five of them achieved remission) in the rTMS subgroup. Thirteen patients were responders (six of them achieved remission) in the antidepressants subgroup. Results of neuropsychological tests showed that rTMS especially improved memory, thinking process and its flexibility, executive functions and verbal fluency.

Conclusion: Our simple blind study confirmed promising effect of high-frequency rTMS in influencing psychopathology and some cognitive functions in patients suffering from depressive disorder.

The study was supported by Ministry of Education of the Czech Republic (VZ MSM 0021622404).

INFLUENCE OF GENDER ON THE CLINICAL PRESENTATION OF GENERALIZED ANXIETY DISORDER (GAD), AND RESPONSE TO TREATMENT WITH PREGABALIN

INSTITUTIONS
1. McMaster University Medical Centre, Hamilton, Ontario, Canada
2. Columbia University, New York State Psychiatric Institute, New York, New York, United States
3. Pfizer Global Pharmaceuticals, Pfizer Inc, New York, New York, United States

AUTHORS
1. Michael Van Ameringen
2. Moira A. Rynn
3. Francine Mandel
4. Barry Herman

Aim/Objective: This retrospective analysis evaluated gender differences in the clinical presentation of GAD and response to treatment with pregabalin (PGB).

Methods: Data were pooled from six multicenter, double-blind, placebo-controlled, 4-6 week trials of outpatients with DSM-IV GAD and a minimum HAM-A total score >18. Treatment response was analyzed for three fixed-dosage groups, 150mg/d, 300-450mg/d, and 600mg/d.

Results: The baseline presentation of GAD was similar for women versus men, respectively, in terms of mean (+SD) age (38.6+12.3 vs 39.4+11.5 years) and severity of concurrent depressive symptoms (HAM-D score, 13.7+4.4 vs 13.4+4.3); however, women had a modest but significantly higher mean HAM-A somatic factor score (11.5+3.2 vs 10.8+3.1; P<0.01). For both women and men, treatment with PGB resulted in significantly higher LOCF-endpoint improvement in HAM-A total score: Women: PGB-150mg, -10.7+0.82; PGB-300/450mg, -11.8+0.62; PGB-600mg, -11.6+0.51 vs Placebo, -9.5+0.51 (P<0.0001 for all comparisons); Men: PGB-150mg, -10.8+0.81; PGB-300/450mg, -12.6+0.59; PGB-600mg, -11.6+0.51 vs Placebo, -8.7+0.47 (P<0.0001 for all comparisons). There were no between-dose differences in treatment response for either women or men in the recommended dosing range of 300-600 mg/day. CGI-I responder rates were significantly higher (P<0.001) on PGB versus placebo for both women (30% vs 35%) and men (33% vs 38%). There were no gender differences in attrition due to adverse events, or in proportion of severe adverse events.

Conclusion: Women and men with GAD showed similar clinical presentations, with the exception that women reported somewhat more somatic symptoms. Pregabalin was an effective and well tolerated treatment for GAD in both women and men.

CRISIS THERAPY INTERVENTION IN PANIC DISORDER

INSTITUTIONS
1. Clinical Emergency Central Military Hospital, Psychiatry, Bucharest, Romania

AUTHORS
1. Daniel Vasiile, Dr., MD, PhD
2. Octavian Vasiu, Dr., MD
3. Mihaela Vasiile, Ms., MD
4. Oana Cretu, Mrs., MD
5. Mihai Terpan, Mr., MD

Objective: Crisis therapy is an instrument that could improve prognosis of panic disorder patients when it is applied in the hospitals emergency rooms [1]. As objective of our study we focused upon the efficacy of early psychotherapeutic interventions in patients diagnosed with panic disorder.

Methods: A group of 37 patients, 23 female and 14 male, mean age 37.3, diagnosed with panic disorder, received psychiatric assistance in the emergency room of our department. We used crisis intervention, with focus on relaxation methods, normalizing, assurance and explanation of cognitive-behavioural panic model [2]. We assessed these patients using Acute Panic Inventory (API) and Hamilton Rating Scale for Anxiety (HAM-A) before the crisis intervention as well as after 48, 72 hours and after 7 days.

Results: The anxiety symptoms in patients with panic disorder decreased significantly after crisis intervention as API (-15.2 points) and HAMA (-5.4 points) scores showed after 48 hours. However, patients who didn't enter in a structured psychotherapeutic and/or anxiolytic drug treatment after the initial intervention presented a gradually increases in anxiety level, with API and HAMA scores greater than treated patients (+10.2 and +7.6, respectively, at 7 days).

Conclusion: Patients with panic disorder receiving crisis intervention improved significantly, but they also should be supported by a medium to long term psychotherapeutic and/or anxiolytic treatment.

3. Silvia Falconi1, Mrs., PhD
4. Vilma Vite1, Mrs., PhD
5. Freddy Alberto Vasquez1, Dr., MD, freddyalber@hotmail.com

OBJECTIVE: Study of suicide-filicide cases checking demographic and clinical features to understand this phenomenon.

METHODS: A prospective trial of cases of suicide-filicide behavior seeing last 5 years regarding demographic and lawful files, also clinical diagnosis adjusted to DSM IV criteria.

RESULTS: We studied 8 mothers with suicide-filicide profile, 5 of them survived and their children died, while in other 3, mothers and children survived. Mother's age was between 18 to 38 years old. Only 2 mothers were married. 4 mothers had a high school degree, 3 primary school and one a university degree. Major Depressive Disorder was diagnosed in 5,1 of them with psychotic features, other with Bipolar Disorder, in the latest 2 diagnosis was acute Psychosis. In all cases, psychological abuse was showed, familial crisis, and home escape by partners. 3 mothers justified their attitude evoking child suffering. In all cases method was poisoning. Age in died children was 2 to 5 years old, in survived 4 months and 8 years old. 3 filicides made a new suicide attempt because of guilty feeling, a hard stressor on judge's determination over child care, fear or shy

CONCLUSIONS: Common factors in suicide-filicide behavior in the study: young mothers, home crisis, all depressed worsened by partners' abuse or home escape, poisoning as the prevalent method and fear about the continuity on maternal care .A tragedy increasing in developing countries.

PROJECT OF INTERVENTION IN CORONARY PATIENTS WITH AND WITHOUT MAJOR DEPRESSION FROM ARZOBISPO LOAYZA NATIONAL HOSPITAL, LIMA, PERU

INSTITUTIONS
1. Arzobispo Loayza National Hospital, Psychiatry, Lima, Peru

AUTHORS
1. Isabel Vasquez1, Dr., MD, pochivasquez@yahoo.com
2. Pedro Nuñez1, Dr., MD, pedronuneztorres@yahoo.es

Aims - Know depressive major disorder (DMD) prevalence in coronary patients with or without IAM from HAL Cardiology External Consultation and Coronary Intensive Care Unit (UCICOR). - Follow two cohorts (patients with and without DMD) and offer psychiatric treatment for patients diagnosed ofDMD. - Evaluate rates of IAM-IAM2 cohorts with and without DMD. Later, in cohort with DMD, compare whose receive treatment against whose refused or left it. - With the results, design a program for DMD prevention, detection and treatment for HAL coronary patients.

Material and methods: - Included: patients with coronary disease of ambulatory consultation and UCICOR, with or without DMD. Excluded: with another mental disease. - Clinical interview, application of measurement and diagnosis scales (MINI, depression section and Hamilton's scale for depression). Assignment to cohorts: with and without DMD's diagnosis, and with DMD, whose conclude or not their treatment. - Pharmacological and psychotherapeutic treatment for patients with DMD. - UCICOR's report in case of revenue - Evaluation of exit after one year. - Comparison of the occurrence of coronary events between cohorts.

Results: We hope that patients without DMD will present a minor IAM-IAM2 rate that patients with DMD and, inside cohort with DMD, this rate will be minor in patients who conclude treatment.

Aims/objectives: The course and short-term treatment of depression disorders have been extensively studied. Since there is a high risk of recurrences in depression disorders and given the fact that there is a wide range of patients showing residual symptoms even after an adequate initial response to treatment, it is still necessary to study middle-term and long-term treatment of depression.

Methods: In the present study we identify clinical trials aiming to evaluate the long-term treatment of depression. We searched for all published double-blind randomized clinical trials including an acute-treatment phase that, after achieving an adequate treatment response and/or therapeutical remission in patients diagnosed of major depression disorder, randomized these patients to a pharmacological treatment-maintenance period of at least 24 months. Research of the published literature until October 2007 was performed both in Pubmed and the Cochrane Controlled Trials Register database.

Results: 13 clinical trials, published between 1982 and 2007 were selected. Three showed a duration of 36 months (one of them with a 60-months follow up extension), one showed a 25-months and the remaining nine, with a 24-months follow up period. Among the used drugs we found: tricyclic antidepressants (Imipramine (3), amitriptyline, nortriptyline (2) or similar (desipramine, dotiepine); MAOIs (phenelzine); SSRIs (fluvoxamine/sertraline, sertraline and paroxetine) and SSNRI's (venlafaxine).

Conclusion: Data in this systematic review show that there are very few studies regarding long-term treatment of depression. Future clinical trials should include longer maintenance treatment periods that contribute to understand the treatment of chronic depression.

DEPRESSION AND GLOBALISATION: THE PERSONAL REPRESENTATION OF A POLITICAL PROBLEM

INSTITUTIONS
1. University of Brighton, School of Applied Social science, Brighton, United Kingdom

AUTHORS
1. Carl J Walker¹, Dr., PhD, c.j.walker@brighton.ac.uk

Depression can be a life-wrecking, painful experience for sufferers and their families. Moreover the number of people suffering from depression has increased considerably in recent years. My talk will centre on my most recent book (published December 2007). The rebirth of the new right in the 1970’s meant that in country upon country, markets were deregulated, state planning and power dismantled, welfare was cut and/or criminalised and full employment policies abandoned. Moreover the economic discourses of globalisation have shaped the way that we understand, represent and treat depression in the western world. We have focused too much on individualistic factors and neglected the social and political context within which we all operate. The psychological sciences exist in a paradoxical territory where their systems of treatment also represent tacit support for the political system that creates such harmful circumstances in the first place. The focus on the psychology of the individual as this unit of investigation has been rewarded in the current economic and political climate. This work offers a critical synthesis of the way that changes in social inequality and poverty, in conjunction with an individualistic political and academic focus, have acted to create the conditions that will continue to make depression a profound and disabling health issue well into the 21st century.

5. Lilach Rachamim¹, Dr., PhD
6. Ayala Daie¹, Dr., PhD

We aim to explore the effects of self-critical perfectionism (SC) on the outcome of Prolonged Exposure therapy (PET) and Brief Psychodynamic therapy (BPT) for Posttraumatic Stress Disorder (PTSD) in adolescent victims of single event traumas. Previous studies have marked SC as a vulnerability factor for depression, for both adolescents and adults. Additionally, Blatt et al. (1) have shown that SC has an adverse effect on the outcome of brief therapy for depression. The effect was found for both cognitive behavioural and psychodynamic treatment methods. Moreover, SC has been identified as a vulnerability factor for the development of PTSD symptoms. So far, no research has examined the effects of SC on the outcome of interventions in anxiety disorders, in particular PTSD. In light of previous findings, we have hypothesised that SC would have an adverse effect on the outcome of PE and AP in PTSD. Participants were 35 adolescents (mean age 14, range 11-18) diagnosed with PTSD who completed either PE (n=18) or AP (n=17) therapy. A preliminary analysis of the data has revealed an association between SC severity of PTSD, depression and general anxiety at the onset of treatment. However, SC did not affect any of the emotional distress indices at the end of treatment. These findings are discussed in view of the differences in treatment of anxiety vs. depression, adolescents vs. adults, and personality vulnerability on treatment efficacy.

rTMS TREATMENT OF DEPRESSION - RESULTS UNDER NATURALISTIC CONDITIONS

INSTITUTIONS
1. University of Regensburg, Psychiatry, Regensburg, Germany

AUTHORS
1. Silvia S. Wilfurth¹, Mrs., silvia.wilfurth@medbo.de
2. Peter Eichhammer¹, Dr., MD
3. Elmar Frank², Dr., MD
4. Michael Langgrebe³, Dr., MD
5. Goeran Hajak², Prof. Dr., MD, PhD
6. Berthold Langguth³, Dr.

OBJECTIVES: Repetitive transcranial magnetic stimulation (rTMS) is increasingly used in clinical practice, especially for the treatment of drug-resistant depressive syndromes. A large number of controlled studies strongly suggest antidepressant efficacy of rTMS. However, systematic observations of optimal stimulation parameters and clinical relevance under naturalistic conditions are still lacking.

METHOD: Between July 2004 and June 2007 101 patients with drug resistant depression were treated with rTMS in the centre for non-invasive brain stimulation at the district hospital of Regensburg. 2000 stimuli of rTMS (40 trains with an intertrain interval of 25 seconds) with a frequency of 20 Hz and an intensity of 110% of the motorthreshold were applied daily from Monday to Friday over the left dorsolateral prefrontal cortex.

RESULTS: In 93 cases treatment was terminated as planned, in 8 cases it was terminated earlier for various reasons. No severe side effects were observed. In average patients received 16.2 ± 6.5 treatment sessions. The average score of the Hamilton depression rating scale before treatment was 24.1 ± 7.4, after treatment 15.7 ± 8.3. 32 patients had an improvement of their Hamiltonscore of 50 % or more.

CONCLUSION: These results indicate, that rTMS represents a practicable, safe and well tolerated treatment option in clinical practice. Treatment effects are clinically relevant. However it has to be considered that the data come from a clinical observation under naturalistic conditions.

DIAGNOSIS OF PEDIATRIC BIPOLAR DISORDER: CLASSIC OR ATYPICAL?

INSTITUTIONS
1. Massachusetts General Hospital/Harvard Medical School, Pediatric Psychopharmacology, Boston, MA, United States

AUTHORS
1. Janet Wozniak, Dr., MD, jwozniak@partners.org
2. Eric Mick, Dr., ScD, emick1@partners.org
3. Joseph Biederman, Dr., MD, jbiederman@partners.org

Background: Debate regarding the prevalence of pediatric bipolar disorder has focused on its defining features, specifically the mood component (irritable or euphoric) and the cycling pattern (episodic or chronic). The goal of this study is to examine symptoms profile, comorbidity and familiality based on these clinical correlates.

Methods: Subjects were youth (≤18 years) who satisfied DSM-IV criteria for bipolar disorder on structured diagnostic interview (KSADS) who had been consecutively referred to a family study of pediatric bipolar disorder. Subjects (N=107) were studied in regards to symptom profile, cycling patterns, functioning, patterns of comorbidity, and family history.

Results: We examined patterns of familiality based on combinations of mood state and cycling, examining those with euphoric mood (37%), irritable mood (91%), clear cycling pattern (12%) and chronic symptom picture (88%; 12% rapid, 27% ultra-rapid, 1% ultradian, 7% episodes longer than 12 months, 41% one episode longer than 12 months). We found no differences (p<0.01) in symptoms, comorbidity, or familiality of bipolar disorder, whether stratifying by the presence of irritability (14% familiality) or euphoria (13% familiality). Grandiosity versus no grandiosity was associated with greater familiality of bipolar disorder, but this was also true of other criterion B symptoms. We found no differences in familiality when stratifying by episodic (11%) or chronic course (13%).

Conclusion: The clinical correlates of course (episodic or chronic) or mood presentation (euphoria or irritability) were not useful in defining a distinct subtype of pediatric bipolar disorder based on symptoms, comorbidity or familiality.

2. Aslan Guzel, Dr
3. Yusuf Tamam, Dr

Aims: Although traffic accidents are more common in developing countries than in the developed ones (1), prospective studies investigating the PTSD ratios are limited (2). We aimed to find out the PTSD ratios in people who have had a traffic accident, and the variables affecting this ratio.

Methods: 95 subjects were included in the study and were evaluated at 4 different times; in the beginning, after 3 months, 6 months and 1 year. 

Results: During the first evaluation, 41.1% (39) of our participants had ASD. It is found the lower perceived social support (OR=0.0908, CL=0.834-0.989, p=0.027) and higher disosyasyon score (OR=1.332, CL=1.170-1.516, p<0.001) as significant predictors of ASD. After 3 months, 6 months and 1 year of the accident, we found PTSD (respectively) in 29.8%, 23.1% and 17.9% of the subjects. Although, limitation at work and social life after traffic accident was not related to PTSD at 3 months (OR=122.43, CL=0.000-, p=0.999), limitation at work and social life predictors for PTSD at 12 months (OR=155.514, CL=2.321-104.22, p=0.019)

Conclusion: it was found that the development of PTSD at 3 months after traffic accident to be related ASD, peritraumatic dissoisiatif scores and the social support scores. The persistence of PTSD at 12 months evaluation is related, to limitation work and social life, the lover social support scores.

THE ROLE OF GENDER AND TRAUMA TYPE IN PREVALENCE OF PTSD IN A POPULATION LIVING IN A REGION WITHIN THE AREA OF CONFLICT: A “TURKEY” MODEL

INSTITUTIONS
1. Dicle University Faculty of Medicine, Department of Psychiatry, Diyarbakir, Turkey
2. Dicle University Faculty of Medicine, Public Health, Diyarbakir, Turkey

AUTHORS
1. Aziz Yasan¹, Dr., M.D., siyasen@hotmail.com
2. Günay Saka², Dr., MD
3. Mustafa Ozkan¹, Professor, M.D
4. Meliksah Ertem¹, Professor, M.D

Aims: Studies conducted in this regard have reported that response to trauma differs, and different psychopathologies might develop according to gender (1). We planned to investigate the role of gender and trauma type in prevalence of PTSD and other psychopathologies in people who live within the area of conflict.

Method: In the conflict area, a list of 750 houses was produced by randomly choosing 50 separate sets representing the provincial center. Information about the demographic characteristics, traumatic experiences of the and PTSD 708 participants (women: 398, men 310) was obtained.

Results: Although men (52.9%) experience more traumatic life events compared to women (44%), there was no difference between genders regarding lifetime (men: 73.8%, women 72.6%) and current PTSD rates (female: 28%, male: 32.3%). While it was determined that, compared to women, men have higher rates of lifetime PTSD among those who experienced forced migration as a type of traumatic life event without additional trauma, we found that among those who experienced earthquake, lifetime PTSD rates were higher in women than in men. Among those who received death threat, and who experienced forced migration without additional trauma, PTSD rates were higher in men than in women.

Conclusions: According to our findings, it can be concluded that traumatic life experience can be determinative in relations between PTSD and gender, depending on gender-related social roles and some cultural characteristics.

COMORBIDITY AND PSYCHOLOGICAL DIFFERENCES AMONG PATIENTS WITH ANXIETY DISORDERS

INSTITUTIONS
1. Dokuz Eylül University, School of Medicine, Psychiatry, Izmir / Balçova, Turkey
2. Dokuz Eylül University, School of Medicine, Psychiatry, Izmir / Balçova, Turkey

AUTHORS
1. Doğan İskik¹, M.D., drdoganisik@gmail.com
2. Beyazıt Yemez², M.D., beyazıt.yemez@deu.edu.tr

Objective: The aim of this study is to determine differences between anxiety disorder subgroups in terms of anxiety sensitivity, state and trait anxiety, worry and disability levels and comorbidity.

Method: Drug free patients were diagnosed with MINI, a structured diagnostic interview. Those who had a principal diagnosis of one of the DSM-IV anxiety disorders were asked to fulfill a package of psychological tests (STAI, ASI, PSWQ, BDQ).

Results: There was a significant difference between groups according to ASI scores. Post hoc analysis revealed that patients with GAD (n=50) and PD (n=30) were more sensitive to anxiety than all the other groups except PTSD (n=8). There were no differences between GAD and PD groups nor between the other groups. Patients with GAD had significantly higher scores both on state and trait anxiety than all the other groups (p<0.001) except OCD (n=31) and PTSD groups. Patients with GAD had significantly higher scores on PSWQ than the PD and AD-NOS (n=49) groups (p<0.05). In terms of disability there were no significant differences between groups. Comorbidity was highest in the GAD group (74%) while in the other groups it ranged between 12-37.5%. Patients who had a comorbid disorder had higher scores on ASI, STAI-T, STAI-S (p<0.001) and on PSWQ (p<0.05).

Conclusion: Anxiety sensitivity is high among GAD patients as well as PD patients but this might be because of the high comorbidity rates in GAD patients. Anxiety sensitivity, state and trait anxiety are prominent risk factors for comorbidity among anxiety disorders.

2. Ege University School of Nursing, Izmir, Turkey

AUTHORS
1. Serap Yıldırım¹, Mrs., camserap@yahoo.com
2. Esra Engin¹, Dr., PhD, esraengin@yahoo.co.uk
3. Gulsen Altinoz², Mrs.

Objective: The study aims at comparing the state-trait anxiety levels of patients with multiple sclerosis and non-patients individuals.

Method: The sample of the research consisted of 80 patients and 80 healthy individuals who were registered at the Multiple Sclerosis Foundation and Ege University Faculty of Medicine Polyclinic for Neurology and either attended meetings at the foundation or applied to the polyclinic during March-April-May 2006. Having received necessary permission form institutions, patients and healthy individuals, the data was collected through Introductory Information Form and State-Trait Anxiety Inventory (1,2).

Results: While the state anxiety level of patients with multiple sclerosis was 51.20±3.0, the level of healthy individuals was determined to be 42.63±6.42. When the state anxiety levels of patients and healthy individuals are compared the difference between the scores seemed statistically meaningful (p<0.001). On the other hand, the trait anxiety level of patients with multiple sclerosis was 47.16±7.24 while that of healthy individuals was 49.06±6.89 and the difference between the scores was determined not to be statistically meaningful (p>0.05).

Conclusion: It was concluded that the state anxiety level of the patient group was high and this result was caused by the existing health problem.

CLINICAL AND IMMUNOLOGICAL CORRELATION AND TREATMENT OF ENDOGENIC DEPRESSION

INSTITUTIONS
1. Medical University, Psychiatry, Rostov-on-Don, Russian Federation

AUTHORS
1. Vladimir Zaika¹, Dr., MD, PhD, zaika@ctsnet.ru

Inspite of introduction in clinics of modern anti-depressants, questions about the effectiveness of treatment of depression remain relevant. The aim of the investigation was to assess the connection between the clinical state of the patients, indices of activity of neuro-immune, kinin and anti-oxidant systems. 105 patients with endogenic depression were examined. State of all patients according to criteria of DSM-IV corresponded to "major depressive episode". Serum immune complexes, activity of kinin systems and state of free-radical processes were determined before and after 4-week course of anti-depressive treatment. An increase of immune complexes by 98% at patients with bipolar affective dysfunctions (ICD-10) was revealed and at patients with recurrent affective dysfunction the increase was 83% in comparison with the control group. During schizo-affective psychosis and schizophrenia the immune complexes were higher by 101% and 124% respectively. Activity of kallikrein and also of free-radical processes were increased in all investigated cases. Neuroimmune processes are suppose to participate in the pathogenesis of endogenic depression and to be important in its effective treatment.

DOES THE ENDOGENOUS DHEA AND SDHEA INFLUENCE THE LEVEL OF PLASMA LIPOPROTEINS IN WOMEN WITH DEPRESSION?

INSTITUTIONS
1. Bielanski Hospital, Psychiatry, Warsaw, Poland
2. Institute of Psychiatry and Neurology, IV Department of Psychiatry, Warsaw, Poland

AUTHORS
1. Bertrand Janota1, Dr, MD, bertrand@mp.pl
2. Maria Zaluska2, Dr, PhD, zaluskam@acn.waw.pl

Introduction: There are some evidence that in depression the level of DHEA is lower, and of cortisol higher than normal [1]. It is suggested that high cortisol /DHEA ratio influences negatively the blood lipoproteins and cardiologic risk in depression; However in the epidemiological studies the low level of DHEA in men, but not in menopausal women is connected with increased cardiologic risk [2].

The aim: assessment of cortisol, DHEA, and SDHEA blood level, and its correlation with the blood lipoproteins in depressive women in the course of the treatment with fluvoxamine with the special reference to age, stress, anxiety and depressive symptoms.

The method: 20 depressed women and 20 healthy control volunteers aged 18 - 65 years will be investigated - before and after 3 weeks of therapy with fluvoxamine. The blood level of cortisol, DHEA, SDHEA and lipoproteins will be measured in dexamethason suppression test. The level of depression, and anxiety will be assessed with Hamilton scale. The Holmes and Ray questionnaires for stress will be used.

Results: 14 depressive females and 6 controls were investigated. The preliminary results will be analyzed and presented

Statements: the investigation will be continued.

AIMS: To study the pattern of changes of plasma homovanillic acid (pHVA) in Bipolar I patients during the treatment with olanzapine and lithium. And to analyse if the family history of psychosis permits to distinguish a singular subgroup of patients.

METHODS: We have studied 46 (27 women and 19 men) Bipolar I patients with psychotic mania that have not received medication for, at least, eight days. Patients were treated with 10mg/day of olanzapine. On the fourth day the dose was increased to 20 mg/day. After a week lithium was added until achieve a lithemia of 0.6-1.0mEq/L. Clinical status of the patients was evaluated with the Young rating scale for mania. Blood was collected for pHVA after 13 hours of fasting, on the first morning after admission, and during treatment.

RESULTS: Plasma HVA does not decreased after 28 days of the olanzapine plus lithium treatment (mean variation±SD, 0.66±5.58ng/ml), maybe due to the addition of lithium. Clinical improvement tended to positively correlate with pHVA levels on the 28th day. Then, we divided the patients into two groups: 25 patients with first degree relatives (FDR) with psychotic disorders (mostly bipolar: 95%), and the other group of 21 subjects with no FDR with psychosis, and the analysis showed that only in the patients with psychotic relatives this correlation was significant (r=0.472, p=0.017).

CONCLUSIONS: In Bipolar patients positive family history of bipolar disorder may constitute a good basis for sub-grouping these patients. In appropriate experimental conditions, pHVA can be a useful tool in psychiatry research.
SURVEY OF RELATION BETWEEN POSITIVE AND NEGATIVE SYMPTOMS IN SCHIZOPHRENIC PATIENTS WITH HISTORY AND RISK OF SUICIDAL ATTEMPT IN EBNESINA HOSPITAL

INSTITUTIONS
1. Mashhad University of Medical Sciences, Psychiatry, Mashhad, Iran (Islamic Republic of)

AUTHORS
1. Ebrahim Abdollahian1, Dr., MD, abdollahian@mums.ac.ir
2. Mitra Sadat Forghani1, Dr., MD, ebramck@yahoo.com

Objectives: To evaluate the relation between positive and negative symptoms in schizophrenic patients with history and risk of suicidal attempt.

Method: This case-control study was done on 65 schizophrenic inpatients during the years 2006-2007 and 65 major depressive disorder patients as control group. Both of these groups were evaluated and compared on base of clinical assessments and California diagnostic tests and PANSS (positive and negative syndrome scale).

Results: There was significant relationship between positive symptoms in schizophrenic patient and both the California number test \( r=0.708, p<0.0001 \) and history of suicidal attempt \( r=0.558, p<0.0001 \). Also there was significant and reverse relationship between negative symptoms and both the California number test \( r=-0.529 \) and history of suicidal attempt \( r=-0.512 \). That means rising negative symptoms decrease the risk and history of suicidal attempt.

Conclusion: Regarding the results of this survey, schizophrenic patients with positive symptoms such as paranoid schizophrenia have more insight to their illness and probability of depression and increased risk of suicide. Schizophrenic patients with negative symptoms such as deficit Schizophrenia, have less insight to their illness and low probability of depression and risk of suicide.

QUALITY OF LIFE, SOCIAL FUNCTIONING AND SATISFACTION IN PATIENTS WITH DIAGNOSTIC OF SCHIZOPHRENIA IN CHILE

INSTITUTIONS
1. Faculty of Medicine, Universidad de Chile, Psychiatry and Mental Health, Campus Oriente, Santiago, Chile
2. Faculty of Medicine, Universidad de Los Andes, Psychiatry, Santiago, Chile
3. MINSAL, Mental Health Unit, Chile

AUTHORS
1. Julia Acuña1, Dr., jacuna@med.uchile.cl
2. William Jadresin2, Dr., wjadresin@gmail.com
3. Cynthia Zavala3, Dr., czaval@gmail.com
4. Alberto Botto1, Dr., abottov@hotmail.com

Objective
To describe the perception of quality of life, social functioning and satisfaction of patients with Schizophrenia attending Public Mental Health Services in Chile.

Methods
336 patients were randomly selected in 8 clinic units, representative of the Public Mental Health of Chile (11.020 patients in treatment). Mental health professional, were trained for using the instruments with satisfactory interater reliability test; then they applied WHO Quality of life-brief (WHOQOL-BREF), Groningen Social Disabilities Schedule (GSDS) and Communication Satisfaction Questionnaire (CSQ-8) between September 2002 to January 2003 to patients selected.

Results
63.19% of patients interviewed were men with 41.5 years old average age. The average time of disease was 17 years and 29% receive atypical anti-psychotics for at least 6 months. The general average of quality of life according WHOQOLBREF was "some dissatisfaction": 3.11 (range 1-5). The average of different areas varied between 2.85 and 3.47. Disability reported in terms of social functioning roles(GSDS) was moderate; higher disabilities were for citizen role (2.05), social role (1.94) and partner role (1.93); lowest disability was for selfcare role (1.06) (0= no disability; 3 maximum). The average user score was 3.24: "satisfied" (CSQ-8: 1 unsatisfied-4 very satisfied), for the care they received.

Conclusions
Patients with Schizophrenia have some degree of dissatisfaction with their quality of life, with diverse degrees of social disabilities. However, they declare to be satisfied with the health care they receive.

5. Olga Antoniadou1, Dr., MD
6. Maria Samakouri2, Assistant Prof, MD, PhD
7. Miltiadis Livaditis2, Associate Prof., MD, PhD

Objectives: The examination and evaluation of comparative studies, concerning the efficacy of different kinds of group psychotherapy of psychotic patients in the last 20 years.

Method: Electronic research through Medline was conducted, for the detection of articles related to comparison between different kinds of group psychotherapy with schizophrenic and bipolar patients, published in the English language, from 1986 - 2006.

Results: 11 studies were detected. The commonest comparison is between a psychotherapy of a specialized approach (like learning social abilities) and of a non-specialized approach (such as supportive group psychotherapy), with supremacy of the first. Two studies concern comparison of the behavioral - cognitive model to psycho-education, with supremacy of the first and one reports supremacy of a group for social abilities to another for occupational ones.

Conclusion: There is evidence of the supremacy of specialized approaches of group psychotherapy of psychotic patients towards non-specialized ones, but more studies need to be done in the future for further confirmation. Differences in the process of these studies do not allow meta-analysis. Subjects that request further research and form future questions are if a group psychotherapy model of a specialized approach is superior to another as well specialized model and if some schizophrenic / bipolar patients respond better to a specific model.

CRAZY OR LODESTAR? CULTURE INFLUENCE IN SOCIAL TOLERANCE OF MENTAL ILLNESS

INSTITUTIONS
1. Centro Hospitalario Benito Menini, Acute Psychiatric Unit, Valladolid, Spain

AUTHORS
1. Jose A Aguado1, Dr., jaaguadom@gmail.com
2. Olga Segurado1, Dr., oseguardo@gmail.com

Objectives
To analyze culture influence in a case report of schizophrenia
To observe how culture modulates, integrates and justifies mental illness.
To discriminate psychiatric pathology against superstitions and beliefs, which requires contextualizing.

Method
Case study. Chronopathobiography
Patient's artwork and manuscripts analysis
Diagnostic and Therapeutic Approach
Literature Comparison

Results
Clinical Case
Woman of 30, with lonely and submissive childhood, becomes a rebellious teenager with substances abuse and purgative anorexia. Finally she settled in India, where her illness debuted. She is accepted as guru-lodestar and respected by local population. For her extravagance, she was brought to Spain and entered in psychiatry.

Symptoms and artwork
Speech and drawings convey the existence of mystical delusions related to Hindu mythology. She shows poor affectivity and uses hyper-rational answers to justify her behaviour and delusion in traditional Hindu legends. Illness was compounded by cannabis abuse.

Diagnosis and treatment
Purgative anorexia, cannabis abuse and dependence, paranoid schizophrenia.
Due to absence of treatment adherence, Risperdal Consta 50mg was elected. Day Hospital attendance and Social Skills Psychotherapy were also proposed.

Conclusions
Patient immersion into Hindu culture was decisive as modulator of mystical-religious delusions of the case. Social tolerance of mental ill as San Simeon de Emeza, Diogenes of Sinope.

PSYCHOLOGICAL WELL-BEING AND FACIAL EMOTION RECOGNITION IN SCHIZOPHRENIA

INSTITUTIONS
1. University of Porto: Faculty of Psychology and Educational Sciences, Portugal
2. Higher Polytechnic Institute of Gaya: School of Social and Community Development, Portugal
3. Porto Polytechnic Institute: School of Allied Health Science, Portugal

AUTHORS
1. Susana Correia Aguiar1,2, susana.aguiar@gmail.com
2. Cristina Queiros1
3. Nuno Rocha1,3

Aims: Literature suggests that schizophrenic patients are impaired in facial emotion recognition. The purpose of this study was to analyse if these deficits are related to psychological well-being and whether they tend to be more associated to positive or negative affect.

Methods: 30 participants with schizophrenia engaged in a facial emotion recognition experiment, which consisted of 30 morphed faces with different 6 emotional intensities of happiness, sadness, anger, fear and disgust. For each morph, participants had to decide which of the 5 emotions was being expressed. Psychological well-being was assessed through the Affect Balance Scale1.

Results: There were found significant correlations between facial emotion recognition and general psychological well-being. Negative affect was significantly associated with the total score of the facial emotion recognition experiment and with the recognition of happy and anger emotions.

Conclusions: Emotion recognition seems to be related to the experience of psychological well-being. Particularly, negative affect experiences seem to be partially regulated by mechanisms of recognition of other people's emotions.

4. Shin-ya Tayoshi, Dr, MD, 5. Sumiko Tayoshi, Dr, MD, 6. Satuki Sumitani, Dr, MD, 7. Shu-ichi Ueno, Dr, MD
8. Tetsuro Ohmori, Dr, MD

Aims/Objectives: The aim of the current study is to investigate clinical determinants of subjective well-being in outpatients with schizophrenia.

Method: A hundred and four outpatients with DSM-IV diagnosis of schizophrenia participated in the present study. Their mean age was 40.8 (SD=12.7) years. They completed the Subjective Well-being under Neuroleptic drug treatment-short form (SWNS). Clinical symptoms were assessed using the Brief Psychiatric Rating Scale (BPRS), the Calgary Depression Scale for Schizophrenia (CDSS), and the Drug-Induced Extrapyramidal Symptoms Scale (DIEPSS). Global functioning level was evaluated with the Global Assessment of Functioning (GAF).

All subjects gave us written informed consent. Subjects were excluded if they presented with any organic central nervous system disorder, epilepsy, mental retardation, and severe somatic disorder.

Results: The SWNS score correlated negatively with the dosage of antipsychotics, the BPRS negative symptoms subscale score, and the CDSS score. The SWNS score had a positive correlation with the GAF score. The SWNS had no significant correlation with duration of illness, number of hospitalization, the BPRS positive symptoms subscale score, and the DIEPSS score. A stepwise regression analysis showed that the CDSS score was the most important predictor of the SWNS.

Conclusion: These results show that subjective well-being is influenced by depressive symptoms, suggesting that treatment for depressive symptoms might be important to improve patients’ subjective well-being.

7. Miguel Gutiérrez, Dr, PhD, MIGUEL.GUTIERREZFRRAILE@osakidetza.net

OBJECTIVES
Many authors indicate that dimensional representation of psychotic symptomatology has proved to be a more powerful predictor of outcome than current categorical classification systems (1). Less is known about the prognostic value of affective symptoms in first-psychotic admitted patients.

METHODS
Data were gathered on 112 first-admitted psychotic inpatients. A longitudinal study was carried out with manic, dysphoric, activation and depressive dimensions as independent variables (2); dependent variables were obtained at a three-year follow-up (91 patients) using GAF, Strauss-Carpenter prognostic scale, number of hospitalizations, self-harm attempts and relapses. A logistic regression and a non-parametric test when necessary, were made out.

RESULTS
After adjustment for confounding variables, significant associations (p<0.05) were as follow:
- Depressive dimension with less number of hospitalizations and a better result in the GAF
- Manic dimension with less number of self-harm attempts and better course in work adjustment (Strauss-Carpenter).
- Activation dimension and better work adjustment (Strauss-Carpenter).

CONCLUSION
- Not only psychotic symptoms but also affective symptomatology have prognostic value in psychotic patients.
- First-admitted psychosis should be a proper moment to evaluate affective symptoms.
- Dimension analyses could be better or at least complementary to the categorical classification.
- Depressive dimensions as well as manic and activation dimensions are related to a more benign course of illness.

**Objectives**
Hyperprolactinemia is a common finding in patients treated with antipsychotics. Through the reduction of gonadal hormone concentrations hyperprolactinemia is associated with sexual dysfunction, reduced bone density and osteoporosis as well as with hirsutism and loss of the protective effects of estrogen on cognitive and cardiovascular functions in women. Due to the ubiquity of prolactin receptors in the organism, it is possible that it could have more effects on patients. The aim of this study is to determine the prevalence of hyperprolactinemia and its related factors in patients with chronic schizophrenia.

**Methods**
Levels of prolactin and different biological and anthropometric parameters were assessed in chronic schizophrenic inpatients from a psychiatric hospital (Hospital Psiquiátrico de Conxo, Santiago de Compostela, Spain).

**Results**
We studied 182 schizophrenics (65.9% men) with a mean age of 55.14 years (SD:15.25). Only 19.8% of the sample was treated with antipsychotic monotherapy. Hyperprolactinemia was found in 66.1% of women and 41.3% of men (50% of sample). High prolactin levels were significantly associated (p < 0.01) with number of prescribed antipsychotics and there were no association with age, years of illness, presence of metabolic syndrome (assessed by revised ATP-III criteria) and type of antipsychotic treatment (neuroleptics, atypical antipsychotics or mixed treatment).

**Conclusion**
Hyperprolactinemia has a high prevalence in schizophrenic inpatients in treatment with antipsychotics. The use of antipsychotic polypharmacy represents a risk factor for hyperprolactinemia. Further studies about the effects of maintained high levels of prolactin in schizophrenic patients are needed.

3. Viktorija Vujovic, MRS, PhD
4. Gjorgji Hadzi-Angjelkovski, Mrs, MD
5. Ljubinka Damjanovik, MD

**Aim of the work**
To follow the efficiency of Rispolept Consta in chronic patients with long-term schizophrenic disorder in three levels: cognitive functioning, positive persistent hallucinatory-delusional phenomenon and deficiency signs.

**Material and methods**
In the research we included 30 patients diagnosed by the ICD 10 with Dg. F 20.5. They were from both sexes, randomly chosen, aged 30-60 treated in an out-patient clinic as well as in the Psychiatric clinic, Skopje. The patients were with long-term treatment with conventional neuro-therapy without any significant results. During the research we included the following psychometric instruments: PANSS scale, BPRS, scale to evaluate cognitive functioning and SOFAS scale to evaluate social functional. The patients were evaluated in the beginning of the treatment and after 3 month treatment with Rispolept Consta in dosages for amp. 37.5 mg Lm every two weeks period.

**Results**
Expected effects on the part of Rispolept Consta in patients with residual schizophrenia on cognitive, hallucinatory-delusional, behavioral field and positive effects for social functional, better therapeutically compliance and adherence.

EXAMINING PARENTAL BONDING IN A GREEK SAMPLE OF SCHIZOPHRENIC PATIENTS AND RELAPSE

INSTITUTIONS
1. Larissa University Hospital, Psychiatric Clinic, Larissa, Greece
2. University of Thessaly, Medical School, Larissa, Greece
3. University of Thessaly, Medical School, Larissa, Greece

AUTHORS
1. P Avagianou¹, Dr. Psychologist, Ph D, penavagia@yahoo.gr
2. O D Mouzas², Lecturer, Ph D
3. N V Angelopoulos³, Professor, Ph D

Aims/Objectives: Bonding between mother and child is described as a complex two-way process ensuring the needs of the child for nurture and protection. From its conception attachment theory was a theory of normal development as well as a theory of psychopathology. Parental bonding is linked with a variety of psychiatric disorders in adulthood. There is clinical evidence to suggest distorted parental bonding in schizophrenic patients in a variety of studies. The objective of the present study was to investigate the relationship between different types of maternal and paternal bonding in 30 patients with psychotic symptoms and their relapse status.

Methods: Information about maternal and paternal bonding was assessed by the Parental Bonding Instrument (PBI) and readmission to the hospital was considered as relapse.

Results: The results showed that schizophrenic patients who were admitted more than once during a year reported significant differences in parental bonding compared to other patients. In particular, patients with a high relapse rate described their mothers and fathers to be less caring and more overprotective. It needs further research to investigate this fact.

Conclusions: It is important to identify if the patient's perception of the family is distorted, due to the illness and it is important to identify to which extend PBI scales correlate with expressed emotion constructs. Moreover, the results suggest that patients with schizophrenia, unlike patients with other psychiatric illnesses, reported significantly higher paternal lack of care and overprotection. The importance of paternal behaviour in psychotic illness will be discussed.

INFLUENCE OF THE FAMILY FACTORS ON THE SUICIDAL BEHAVIOR OF THE SCHIZOPHRENIC PATIENTS

INSTITUTIONS
1. KCS Institute of Psychiatry, Belgrade, Serbia and Montenegro

AUTHORS
1. Jasmina Barisic¹, PhD, jasminabarisc@yahoo.com

The aim of our research was exploring of the types, models and characteristic of the families with schizophrenic member as significant factors of the suicidal behavior.

The sample consisted schizophrenic patients, who passed the phase with the greatest risk in the development of illness, i.e. the first five years when suicidal behavior is mostly result of the productive symptomatology or insight (disorder awareness). Two schizophrenic groups were researched - with and without suicide attempts during approximately ten years history of disorder.

Our assumption was that family circumstances influences suicidal behavior, particular on the second phase of the illness, when family can represent significant suicidal or protective factor, especially within the depressive subtype (study of Acosta found two suicidal motivation subtypes among schizophrenic - psychotic and depressive).

Test battery was used to estimate family dimensions (Olson's test, Gradir questioner and Bol test).

Statistical analyses (logistic regression) founds that the following profiles are the most significant for the prediction of the suicidal behavior: Profile 1- Exchange, Hunger, Body, Belonging; Profile 2- Cohesion, Individuation, with the characteristics of Order.

Profile 1 indicates that diminishing of these variables increases the chance of suicidal behavior inside the group of schizophrenic without previous suicidal attempts.

Profile 2 indicates that increasing of the statistical significant family variables increase chance for the new suicidal attempts within schizophrenic group with the history of the suicidal behavior.

Searching development predictors of schizophrenia continue constantly. In connection with the universal tendency to ageing the population there was a necessity of studying premorbid features at sick of schizophrenia with debut after 45 years, as has served as the purpose of our research. As methods of research data was subjective and objective anamnesises, and the reduced multifactorial questionnaire of the person which questions were answered with relatives, according to their understanding of behaviour of the patient before the first displays of illness have served. 50 patients have been included in research in the age of from 46 till 68 years. During inspection patients were able to remission. 66% of patients are revealed disorder of person in the form of accentuation, other patients were harmonious persons up to illness. The authentic majority of patients had character disorder on schizoid type (55%), on a share epileptiform accentuation 15% were necessary. At the others of 30% of patients are revealed premorbid features in the form of hyperthymic, unstable, hystero-paranoic, psychasthenic and mosaic accentuation. Deeper personal infringements it has not been revealed at one patient. It has not revealed an authentic difference in premorbid features at patients with various type of current schizophrenic process. It is established, that more often at late age the schizophrenia debut at persons with a disharmonious warehouse of the person in premorbid, in particular schizoid accentuation. It is impossible to exclude influence revealed personal features on becoming of negative frustration at sick of late schizophrenia.

8. Philippe Huguelet1, Dr, CC, Philippe.Huguelet@hcuge.ch

Objectives: To assess country-specific religious affiliations and practices in patients suffering from chronic schizophrenia and to explore if religious coping varies by different social and cultural contexts.

Method: 115 outpatients from Geneva (Switzerland) and 121 from Trois-Rivieres (Quebec), aged 18-65, with a DSM-IV diagnosis of schizophrenia were randomly selected for a semi-structured interview.

Results: Despite of different socio-cultural and religious contexts, religion plays an important role in the daily life of 2/3 of the patients in the two sample (62% vs 68%) and half of them use it to cope with their illness (42% vs 62%). Moreover, both populations reproduce to some extent the same patterns of religious coping: positive sense of self, meaning to their illness and life, comfort, control and support. Principal Component Analysis made on religious variables highlights a very similar factorial structure in both of them.

Conclusion: The clinical implications of religious coping are an important resource in both living contexts. It should be systematically explored for each patient in clinical practice to improve the outcome of schizophrenia.

A SYSTEMATIC REVIEW OF THE INCIDENCE OF BREAST CANCER IN SCHIZOPHRENIA

INSTITUTIONS
1. Eli Lilly & Co Ltd, Medical, Basingstoke, United Kingdom

AUTHORS
1. Chris J Bushe¹, Dr, M.B.B.S, bushe_chris@lilly.com
2. Andrew J Bradley¹, Mr, B.Sc., bradley_andrew_j@lilly.com
3. Hiram Wildgust¹, Mr, PhD

Objectives
The relationship between schizophrenia and cancer has been reported on since 1909. Although few definitive results have emerged these studies have led to hypotheses that rates of cancer may be decreased or increased in schizophrenia patients. We undertook a systematic review of all published data since 1986 reporting incidence data on breast cancer cases in schizophrenia cohorts. We draw conclusions on the relative risk of breast cancer in schizophrenia patients and suggest further research.

Methods
Standard databases were searched for relevant studies using terms including: schizophrenia, neoplasms and breast cancer. Identified studies were reviewed and conclusions drawn as to the relative risk of breast cancer in schizophrenia patients.

Results
13 studies met the criteria for inclusion. 5/13 studies reported significantly elevated risk of breast cancer and 1/13 decreased risk. 7/13 studies report no difference compared to controls. The magnitude and length of studies varied substantially and incident cases of breast cancer ranged 6-370. Cohorts included first-episode patients to median age diagnosis of cancer 61 years. The 4 largest studies report consistent SIR (standardised incidence rate) 1.11 (1.00-1.22); 1.20 (1.05-1.38); 1.15(0.98-1.34) 1.19 and longest person-years follow up (288,755-126,659). The most recent study reports adjusted OR 1.42(1.02-1.95).

Conclusions
Some epidemiological studies with high numbers of breast cancer cases and follow up years suggest that breast cancer risk in schizophrenia may be increased by 20-42%. Further studies need undertaking involving large numbers of schizophrenia patients, with >100,000 person years of risk reporting incident risk by age cohort.

DENTAL ANXIETY AND PHOBIA IN PSYCHOTIC PATIENTS VERSUS NORMAL CONTROLS

INSTITUTIONS
1. Hospital virgen Macarena, unidad de hospitalización de psiquiatria, Seville, Spain

AUTHORS
1. Nieves Casas Barquero¹
2. Samuel Leopoldo Romero Guillena¹
3. Ines Garcia Ramirez¹

Aims/Objectives: To study the levels of dental anxiety in schizophrenic patients and to compare with the normal controls. Also to analyze the dental phobia between both groups.

Methods:
Total sample population: 99 subjects
FirstGroup: 49 schizophrenic patients (ICD 10 Criteria)
Second Group: 50 normal subjects as controls
We administer the questionnaire of Dental Anxiety (Weiner et al, 1986) to all the subjects of both samples.

Results and Conclusions:
1 Dental anxiety and somatic anxiety are significantly related according to gender, being higher in women compared to men.
2 Dental and somatic anxiety are significantly higher in the control group compared to the psychotic patients.
3 Crisis of anxiety is significantly higher in the control group compared to the psychotic patients.
4 There are not differences in dental phobia between both samples.

5. Greg Lenhart, Mr., MS, 6. James Harnett, Dr, PharmD, MS

Aims: To evaluate the risk of psychiatric hospitalizations and expenditures across atypical antipsychotics relative to ziprasidone in a Medicaid population with schizophrenia.

Methods: The 2001-2005 Thomson MarketScan Medicaid Database was analyzed to evaluate 12-month risk for psychiatric (ICD-9: 290-299) hospitalizations as well as overall psychiatric expenditures across atypical antipsychotics in adult patients aged ≥18 years with schizophrenia (ICD-9: 295.xx). The treatment cohorts were matched using propensity scores as weights in multivariate models. A logistic regression model was used to evaluate psychiatric hospitalization rates while adjusting for differences in patient demographic and clinical characteristics. Psychiatric expenditures were adjusted to December 2005 dollars and evaluated using a generalized linear model.

Results: A total of 34,918 patients were included in the analysis. The percentage of patients with at least 1 psychiatric hospitalization during 12 months was 29.6% with quetiapine, 30.1% with aripiprazole, and 32.0% with ziprasidone. The odds of having a psychiatric hospitalization while treated with ziprasidone, olanzapine, and risperidone were comparable with olanzapine (1.06, p=0.53) and risperidone (1.21, p=0.05), but was significantly higher for aripiprazole (2.25, p<0.0001) and quetiapine (1.59, p<0.0001). Overall psychiatric expenditures (medication, inpatient, and outpatient costs) for ziprasidone ($8979) were significantly lower than aripiprazole ($11,823, p<0.0001), quetiapine ($10,809, p<0.0001), and olanzapine ($9425, p=0.03) and comparable to risperidone ($9151, p=0.41).

Conclusions: This analysis indicates a comparable risk for psychiatric hospitalization with ziprasidone, olanzapine, and risperidone and a lower risk for ziprasidone versus quetiapine and aripiprazole in a Medicaid cohort with schizophrenia. Ziprasidone was associated with a lower risk for psychiatric hospitalization and lower psychiatric expenditures versus quetiapine or aripiprazole.

6. James Harnett, Dr, PharmD, MS
7. Kafi Sanders, MPH

Aims: To evaluate the relationship between maximum dose of ziprasidone and time to discontinuation in clinical practice.

Methods: The 2001-2005 Thomson MarketScan Medicaid Database and the 2001-2006 MarketScan Commercial Claims and Encounters Database were analyzed for maximum ziprasidone doses achieved in patients with schizophrenia/schizoaffective disorder or bipolar disorder. Ziprasidone maximum dose groups were defined as low (20-60 mg/d), medium (61-119 mg/d), or high (120-160 mg/d). Outliers receiving >160 mg/d were considered separately. Time to discontinuation was evaluated across propensity score-matched dosing groups. Cox proportional hazard models were used to adjust for confounding when comparing the high- and medium-dose groups with the low-dose group.

Results: Data were available for 19,301 subjects with bipolar disorder, of which 27.0% received low-dose, 25.4% medium-dose, and 47.6% high-dose ziprasidone. Of those subjects with schizophrenia (n=26,629), 17.1% were receiving a maximum low dose of ziprasidone, 21.4% a medium dose, and 61.5% a high dose. Among the propensity score-matched dosing groups, the respective time to discontinuation for low, medium, and high dose was 85.0, 111.2, and 174.6 days within the bipolar cohort and 87.1, 117.8, and 195.7 days within the schizophrenia cohort (p<0.001 for all comparisons). The hazard ratios for discontinuing therapy were significantly lower for the medium- (0.81, 0.83) and high-dose (0.55, 0.58) groups relative to the low-dose group in schizophrenia and bipolar, respectively.

Conclusion: Patients with schizophrenia or bipolar receiving ziprasidone 120-160 mg/d experienced a statistically significant lower discontinuation rate compared with those receiving lower doses.

6. Pedro Levy, Dr., MD

Aim/Objectives: Several cardiovascular risk factors have been associated to mental diseases, namely schizophrenia and bipolar disorder, as well as to treatment with antipsychotic drugs. Metabolic syndrome, a constellation of truncal obesity, dyslipidemia, disturbed glucose metabolism and hypertension, or each of its components, is associated with an increased risk of cardiovascular morbidity and mortality. The aim of this study was to evaluate the prevalence and evolution of hypertension and disturbed glucose metabolism in psychiatric in-patients treated with antipsychotics.

Methods: This study, conducted from April 2006 to November 2007, included 36 patients recruited from an in-patient psychiatric clinic, aged 19-65 years, with heterogeneous psychiatric disorders. Fasting glucose and blood pressure were evaluated on admission and after 3 to 4 weeks of hospitalization. Diabetes was defined according to the IDF/ADA definition and hypertension according to the ESC/ESH criteria.

Results: On admission, the prevalence of hypertension was 22% (n=8) and of diabetes/impaired glucose regulation 6% (n=2). The second evaluation performed at 3 to 4 weeks of in-stay presented a prevalence of hypertension of 31% (n=11) and of diabetes/impaired glucose regulation of 11% (n=4). Twenty-four patients had the diagnosis of schizophrenia, followed by the diagnosis of bipolar disorder in 10 patients and unipolar depression with psychotic features in 2 patients.

Conclusions: Hypertension and diabetes/impaired glucose regulation are prevalent in this group of patients. Our study revealed an increase in the prevalence of these metabolic parameters during treatment with antipsychotic drugs. Strategies to prevent and treat these abnormalities are very important during hospitalization.

1. Collegium Medicum Universitas Nicolai Copernici, Department of Psychiatry, Bydgoszcz, Poland

AUTHORS
1. Małgorzata M Dabkowska, Dr., MD, gosiadabkowska@yahoo.com
2. Aleksander Araszkiewicz, Dr., MD

The aim of this study was to assess the prevalence and intensity of social anxiety among a group of patients with schizophrenia. Study group consisted of 15 patients with schizophrenia (6 men, 9 women).

Research method: To assess the prevalence of social phobia self-report Liebowitz Social Anxiety Scale was used (1). To assess the level of anxiety the State Trait Anxiety Inventory (STAI) self-evaluation questionnaire was used.

Results: Social anxiety was reported among 86.6% of patients with schizophrenia. 26.6% was noted with a subtype of isolated social anxiety, whereas 60% had a generalized subtype of social phobia. Moderate intensity of social anxiety was presented by 16.6% of patients, quite significant by 20% and severe and very severe by 33.2% of respondents. In the group of patients with schizophrenia intensity of social phobia did not correlate with level of anxiety as state and anxiety as trait. Level of social anxiety did not depending on patients' age.

Conclusion: The prevalence of social phobia among patients with schizophrenia was relatively high.

5. Nadja Sevaljevic1, nadja.s@cg.yu

Schizophrenia (or more precisely - the schizophrenia group) represents a complex neuropsychiatric syndrome whose etiology is still insufficiently researched. Among etiological factors that hold an important place in contemporary researches of this disorder, the most prominent are: Impact of altered genetic expression, viral infection and complications during pregnancy and delivery. We are still unable to precisely determine the etiological relationship between perinatal pathology and occurrence of schizophrenic process in late adolescence. Possible explanations, present in contemporary scientific literature, go into two different directions:

1. Deviant genetic expression, as well as the effect of other pathologic processes (e.g. viral infections), which create disposition for schizophrenia, also lead to a greater possibility for occurrence of gestation or perinatal complications.

2. Perinatal complications lead to cerebral hypoxia and oedema while some authors believe that the regions most susceptible to this pathological process are hippocampus and limbic allocortex because of their vicinity to incisura tentorii whose damages are related to schizophrenic psychosis for a long time.

Our paper comprises a retrospective study of 62 patients hospitalized at Female and Male Acute Ward of Psychiatric Hospital in Kotor, Montenegro, who were diagnosed with schizophrenia following the WHO’s ICD 10 criteria. During the research we monitored the incidence of perinatal pathology within this inpatient population and noted the presence of nonfocal neurological signs (‘soft neurological signs’). We attempted to determine the correlation between disease prognosis and this etiological moment which was pointed out by T. J. Crow in his hypothesis about type I and type II schizophrenia.

4. Branislava Cizmovic2, Dr., scorpion4@cg.yu
5. Aleksandar Tomcuk1, Dr., aleksandart2002@yahoo.com

Ever since the making of first clinical descriptions of psychotic process and distinction of group of diseases which Kraepelin and Bleuler named Dementia praecox and Schizophrenia respectively, we are attempting to identify factors which cause this neuropsychiatric syndrome. Postulates of the role of viral infections hold an important place among theories on this subject matter. In this group there are several conceptual models (retroviral infection, current or active viral infection, past viral infection, virally activated immunopathology, etc). This paper represents a retrospective study of relapse in schizophrenia and schizoaffective psychosis who have been hospitalized at Female and Male Acute Ward of Psychiatric Hospital in Kotor, Montenegro, during the first 10 months of current year. During this period 66 hospitalized patients were diagnosed with schizophrenia or schizoaffective psychosis, following the WHO’s ICD 10 diagnostic criteria. In addition to classic somatic, neurological, and psychiatric examination, the hospital treatment encompassed diagnostic evaluations as well, which included a standard laboratory analysis. The following values were monitored: sedimentation rate, leukocyte count (lymphocyte and polymorphonuclears), value of fibrinogen in serum, and C-reactive protein, as well as their dynamics in relation to the actual mental state of the patient.

CLINICAL AND DEMOGRAPHIC CHARACTERISTICS OF SUICIDAL SCHIZOPHRENIA SPECTRUM IN-PATIENTS WITH A HISTORY OF SUBSTANCE ABUSE

INSTITUTIONS
1. Psychiatry Clinic, Serbia and Montenegro

AUTHORS
1. Nada Djordjevic¹, Dr, MD, nadadjo@ptt.yu
2. Suzana M Tošić Golubović¹, Dr, PhD, gnebojsa@bankerinter.net
3. Dragoslava B Gugleta¹, Dr, MD, dgugleta@ptt.yu
4. Violeta Slavkovik¹, Dr, MD, vpm@bankerinter.net

Objective: Comorbid substance abuse is an increasingly recognized problem among schizophrenic patients, with life time prevalence rates reported at between 16 and 60%. Substance abuse has consequences in terms of social functioning, aggressive behavior, non-compliance, and rehospitalization. The aim of our study was assessing the association of suicidal ideation with clinical and demographic characteristics among substance abusers schizophrenia spectrum in-patients.

Method: In a five years period, 50 ICD X schizophrenic, schizophréniform and schizoaffective disorder patients with comorbid substance abuse treated at Psychiatry Clinic Nis, Serbia, were assessed using clinical assessment of symptomatology using PANSS, Calgary Depression Scale. We also compared obtained results with controls (50 recently hospitalized schizophrenic non-abusers patients). At least half of the substance abusers were using alcohol or cannabis.

Results: The substance abuse group was younger, tended to have their first hospitalization at an earlier age and had a significantly higher severity of illness score on the PANSS, general psychopathology subscore (impulsivity item especially) and had attempted suicide more often. They had nearly twice as many hospitalizations and relapses in the 4 years prior to the study. On the other hand, the groups didn’t differ on the PANSS total score, negative subscore and Calgary Depression score. Substance use was found to be a better predictor of relapse and hospitalization.

Conclusions: High impulsivity could facilitate substance abuse as a maladaptive behavior in response to prodromal or relapse symptoms. Substance abused schizophrenic patients certainly represent a group of individuals who are in high risk of suicidal behavior.

Premorbid adjustment is of particular interest in schizophrenia research because of the proposed neurodevelopmental nature of the illness. Premorbid functioning is related to numerous variables of interest, including negative symptoms, response to treatment, and cognitive performance. On the other hand, emotional recognition deficits have been reported in schizophrenic patients in addition to the well established deficits in attention, executive function, and memory. This study examined premorbid functioning during four age epochs (childhood, early adolescence, late adolescence, and adulthood) as predictor of emotional recognition performance in schizophrenia. The Cannon-Spoor Premorbid Adjustment Scale was used to examine schizophrenic patients. Emotional recognition performance was evaluated using a computer morphing technique to present the dynamic expressions. The task entailed the recognition of a set of facial expressions depicting the six basic emotions (happiness, surprise, fear, sadness, disgust, and anger) presented in 20 successive frames of increasing intensity. Possible relations between emotional recognition performance and premorbid functioning were explored using Spearman rank correlations in the four age epochs. Results indicated greater emotional recognition deficits for the six basic emotions when premorbid adjustment was unfavorable in early and late adolescence. A relation between premorbid functioning and emotional recognition performance in childhood was found just for surprise and any relation in adulthood. The relation between poor premorbid adjustment in adolescence and emotional recognition deficits supports the neurodevelopmental hypothesis of the schizophrenia.

ABOUT CONCEPT OF SCHIZOTYPAL PERSONALITY DISORDER

INSTITUTIONS
1. Serbsky National Research Centre for Social and Forensic Psychiatry, Moscow, Russian Federation

AUTHORS
1. Klembovskaya Elena, PhD, klena17@mail.ru
2. Fastovtsov Grigory, PhD, klena17@mail.ru

Aim of research: The aim of research is to define clinical features of schizotypal personality disorder and place of this state in schizophrenic spectrum.

Material and methods: The cohort of 27 patients with schizotypal personality disorder was examined with clinical psychopathological, experimental psychological and catamnestic methods.

Results: We separated out 2 groups of patients: 1) Patients with personality features according to diagnostic criteria of ICD 10 without any indication to clinical course and disease activity. Theirs mental state was stable and limited with only personality disorder without psychotic episodes in the past. They characterized as "strange", socially isolated with unusual behavior, erased emotional reactions (11 persons) 2) Patients with stabilization of schizophrenic process and good remission of disease (minimal 5 years duration), characterized same personality disorders (16 persons). In this case schizotypal personality disorders is acquired in the result of schizophrenia.

Conclusion: Thus, schizotypal personality disorder is not homogeneous form of mental disorder. It can be a kind of specific personality disorder of schizophrenic spectrum (like "pathos without nosos" (A.V. Snejnevsky) with opportunity of developing of schizophrenia in future also as a result of stopped schizophrenic process and forming of personality disorder.

EXECUTIVE FUNCTIONS AND MOLECULAR GENETIC STUDY IN SCHIZOPHRENIA AND PSYCHOTIC MAJOR DEPRESSION

INSTITUTIONS
1. Alexandria University Faculty of Medicine, Psychiatry, Alexandria, Egypt
2. Medical Research Institute, Genetics, Alexandria, Egypt

AUTHORS
1. Adel M El-Sheshai, Prof., MD, elsheshaiam@yahoo.com
2. Ahmed Rady, Dr., MD, dr_ahmed_rady@yahoo.fr
3. Ismail Ramadan, Prof., MD
4. Ibtisam Abdallah, Dr., MD

Objective: - To identify cognitive impairment in schizophrenia and psychotic depressed patients using the WCST - To assess polymorphisms of interleukin 1 beta gene in both schizophrenic and psychotically depressed patients - To show Schizophrenia and Psychotic depression being distinct psychiatric entities

Methods:
20 schizophrenic and 20 psychotically depressed patients were recruited randomly from the outpatient clinic of Alexandria University, aged between 18-50 yrs, diagnosed according to the DSM IV criteria and scoring 4 or more on CGI for severity. Both arms were subjected to Wisconsin Card Sorting Test WCST 128 computerized version, assessed for Interleukin 1 beta gene polymorphism at the position -511 and scored on the BPRS

Results: - Groups were matched as regards age, sex and severity
- Number of WCST trials administered was 128 (SD 0) and 118.4 (SD 19.7) in schizophrenic and psychotically depressed patients respectively with significant difference (p<0.0001)
- Percentage of errors was 47.2 (SD 10.79) and 34 (15.2) in in schizophrenic and psychotically depressed patients respectively with significant difference (p<0.0001)
- Percentage of perseverative errors was 30 (SD 11.14) and 18 (9.97) in in schizophrenic and psychotically depressed patients respectively with significant difference (p<0.0001)
- Both groups showed no difference as regards distribution of different alleles (Chi = 0.53)

Conclusion: - though performance on WCST revealed poor executive functions in both schizophrenic and psychotically depressed patients there was a significant difference between both groups. this difference was not replicated through assessment of the Interleukin 1 beta gene polymorphism at position -511.

VISUAL EVOKED POTENTIAL VEP AS COGNITIVE CORRELATE ASSESSMENT IN SCHIZOPHRENIA AND PSYCHOTIC DEPRESSION

INSTITUTIONS
1. Alexandria University Faculty of Medicine, Neuro-Psychiatry, Alexandria, Egypt

AUTHORS
1. Adel El-Sheshai, Prof., MD
2. Ismail Ramadan, Prof., MD
3. Ahmed Rady, Dr., MD

Objectives:
- to search whether psychotic major depression and schizophrenia reflect the same spectrum of disorders through a comparative study.
- to emphasise the VEP as an indirect tool for visual processing assessment
- to show Scizophrenia and Psychotic depression being distinct entities

Methods:
20 schizophrenic and 20 psychotically depressed patients were recruited randomly from the outpatient clinic of Alexandria University, aged between 18-50 yrs, diagnosed according to the DSM IV criteria and scoring 4 or more on CGI for severity. Both arms were scored on BPRS and subjected to Visual evoked potential to assess P100 wave in both left and right eyes.

Results:
- Groups were matched as regards age, sex and severity
- P100 on the Rt side was 104.55 (SD 5.62) in schizophrenic patients compared to 95 (SD 5.27) msec in Psychotically depressed patients, P100 on the Lt side was 105.8 (SD 5.41) in schizophrenics compared to 95.85 (SD 5.4) msec in Psychotically depressed patients, the difference was statistically significant (p<0.0001)
- No linear correlation has been found between P100 on both left and right sides and BPRS score

Conclusion:
The study revealed a significant difference between schizophrenic and psychotically depressed patients as regards P100 measured via Visual Evoked Potential, which may reflect a more severe impairment of visual processing in schizophrenic patients.

6. Robin Emsley, Prof., MD, rae@sun.ac.za

Background: The usual way to measure the severity of psychotic illness and clinical change is via clinical rating scales. The extent to which clinical and patient ratings agree is not well known.

Objectives: To examine the agreement of patient and clinical ratings of severity of psychosis.

Methods: Data are from a two year open label single arm study of risperidone long acting injectable. Patients completed, independently of clinicians, the seven point Patient Global Impression of Severity (PGI-S). Clinicians completed the Clinical Global Impression of Severity (CGI-S) and the Positive and Negative Syndrome Scale (PANSS). Measures were contemporaneously administered seven times over two years to 50 patients. Data were analyzed using mixed effects models.

Results: There was a very significant linear association of PGI-S and PANSS total (f=13.7, p<.001) and the PGI-S and the CGI-S (f=17.3, p<.001). The adjusted mean (95% confidence interval) on the total PANSS for each PGI-S point was as follows: Normal, not at all ill' 44.3 (42.6; 46.0), 'Borderline mentally ill' 53.5 (49.9; 57.1), 'Mildly ill' 53.5 (49.7; 57.3), 'Moderately ill' 61.1 (53.3; 68.9), 'Markedly ill' 83.0 (57.8; 108.3). The adjusted mean and 95% confidence interval on the CGI-S for each PGI-S point was as follows: Normal, not at all ill' 1.43 (1.27; 1.58), 'Borderline mentally ill' 2.43 (2.10; 2.76), 'Mildly ill' 2.42 (2.06; 2.78), 'Moderately ill' 3.00 (2.25; 3.74), 'Markedly ill' 4.87 (3.02; 6.72).

Conclusions: Overall patients and clinical raters, blind to patient ratings, showed agreement on severity of psychosis.

The cognitive deficit is recognized as a core characteristic of schizophrenia. There has been a wide debate about the nature, the time of onset and long-term process of the cognitive impairment in schizophrenia. It is not clear if the cognitive deficit is corresponding with the severity of the psychotic symptoms. The aim of the study was to compare the profile and stability over time of individual parameters of cognitive functions during the period of one year from the onset of schizophrenia depending on the course of the illness and to clarify the correlation between the cognitive performance in comprehensive neuropsychological test battery and the severity of the psychopathology in patients treated for the first episode of schizophrenia. The study included 30 patients with the first episode of schizophrenia according to ICD-10 and 15 after one year. Our results are consistent with published opinions that cognitive deficit is an important symptom of schizophrenia and does not originate as late as in the process of the illness or as a result of pharmacotherapy and it correlates with severity of psychopathology and reactivity to treatment (remitters X non-remitters). It may be summed up that cognitive deficit showed a trend to improvement for one year after the first episode of schizophrenia, the tendency being more prominent in remitters. The differences between cognitive performance between remitters and non-remitters are, however, not very prominent in the early stage of schizophrenia.

This work was supported by the Ministry of Education Czech Republic (Project No. MSM0021622404).

AIM: to present results of the investigation of efficacy of combination of risperidone and topiramat in patients with schizophrenia and dominant aggressive behavior.

METHODS: the research comprised 30 patients with schizophrenia according to the DSM-IV-TR diagnostic criteria. Patients were admitted in Vrapce Psychiatric Hospital because of aggressive behavior during psychotic episode in the period from May to September, 2007. The Clinical Global Impression (CGI), Positive and Negative Syndrome Scale (PANSS) were used in order to assess patients' condition. The first assessment was made prior to initiation of the treatment. Patients were assessed daily during period of one week, and following assessments were performed on weekly basis during first month of treatment.

RESULTS: After one month PANSS total score significantly improved in 26 patients. The mean Clinical Global Impression severity score for 26 patients improved from markedly ill to mildly ill. Four patients did not finish the study due to side effects (tremor, sedation, weight decrease).

CONCLUSION: Administration of combination of risperidone and topiramat was clinically beneficial for the patients with schizophrenia and dominant aggressive behavior.

5. Stavroula Sokolaki, Dr., MD, sokola@mail.gr

Aim: Obesity, especially central, and the metabolic syndrome are highly prevalent in psychiatric patients. They are mostly attributed to the use of antipsychotic medication and to lifestyle habits and constitute a significant health concern since they seem to be risk factors for rather serious medical conditions.

Material and Methods: The study sample included 105 patients suffering from schizophrenia (44 females-41.91% and 61 males- 58.09%) aged 36.25±10.03 (range 19-69) and 156 normal control subjects (65 females-41.66% and 91 males- 58.34%) aged 36.03±11.33 (range 19-68). Clinical diagnosis was made according to DSM-IV-TR criteria. Height, weight, waist circumference and number of cigarettes smoked daily were recorded. Duration of illness was calculated based on records concerning the age of first onset of psychotic symptoms. Body Surface Area (BSA) and Body Mass Index (BMI) were calculated as well as % body fat, with the use of LifeWisetM body Fat analyzers no 63-1525.

Results: The ANOVA results suggested a significant main effect regarding diagnosis and gender as well as for their interaction. Scheffe post hoc test demonstrated significant differences between patients and controls regarding body weight (women only, p=0.002), waist circumference (men p=0.002, women p<0.0001), BMI (women only, p<0.001), BSA (women only, p<0.01) and % body fat (women only, p=0.033), with patients being more obese. The patients also smoked more cigarettes daily (men p=0.002, women p=0.016).

Discussion: The results of the present study corroborate the increased prevalence of obesity in schizophrenic patients, especially female. The interpretation of this finding remains unclear.

ATTRIBUTIONAL BIASES IN SCHIZOPHRENIC PATIENTS WITH PERSECUTORY DELUSIONS

INSTITUTIONS
1. Chung Yuan Christian University, Department of Psychology, Chung-Li, Taiwan Republic of China
2. Cathay General Hospital, Department of Psychiatry, Taipei, Taiwan Republic of China

AUTHORS
1. Hung Fu-Chien, Dr., PhD, hfc@cycu.edu.tw
2. Tsan Ying-Ying

Background and purpose: Persecutory delusions are the most common type observed in clinical practice and have recently become the focus of empirical researches. In a series of study mainly from Bentall and his colleagues, patients with persecutory delusions were shown to have a tendency to attribute negative events to external causes and positive events to internal causes which seems to be an extreme form of the self-serving bias. However, there aren't the consistent conclusions yet. Therefore, the aim of present research is to investigate if there is an attributional bias in the schizophrenic patients with persecutory.

Methods: A total of 60 subjects were recruited. There are fifteen individuals in each groups which are classified as schizophrenia with persecutory delusion, schizophrenia with non-delusion, depression and control. Using the translatable overt attributional questionnaire (CIPSAQ), the attributional style of all groups were measured and compared.

Results: In overt attribution, a t-test conducted on the scores of externalizing bias (EB) reveals significance in schizophrenic patient with persecutory delusions, but not the personalizing bias(PB).Four groups show no significant differences between group in any of the three attributions as either internal, personal or situational.

Conclusions: The study only partially demonstrated the overtly extreme self-serving bias in schizophrenic patients with persecutory delusions. As a whole, the study may not replicate those of previous studies in demonstrating excessively self-serving bias, but the tendency can be found. Other factors that influence the study and future implications were discussed.

7. Krzysztof Zboralski⁵, Dr, MD, PhD

Schizophrenia is a disease etiopathogenesis of which is not fully explained. There been many studies from independent centers presenting an essential role of reactive oxygen species (ROS) in schizophrenia pathogenesis.

The aim of work: Evaluation of copper - zinc superoxide dismutase (CuZnSOD) activity and evaluation of superoxide anion generation in whole blood in schizophrenic patients.

Material and methods: 19 people (14 men, 5 female) suffering from paranoid schizophrenia took part in the study. Control group consisted of 19 healthy people. Superoxide anion generation by granulocytes was indicated by Bellavite and coop. method. CuZnSOD activity was indicated by Misra and Fridovich method.

Results: Statistically remarkable increase of superoxide anion generation was observed both at rest as well as at zymosane stimulation by whole blood granulocytes. No changes in CuZnSOD activity was observed in control groups.

Conclusion: Our results indicate that schizophrenic patients suffer from pro- and antioxidant balance disturbances in the direction of oxygenating processes. Participation of free radical reactions in pathogenesis is suggested.

Key words: superoxide anion, superoxide dismutase, schizophrenia

Introduction: Psychiatric disorders are common in patient with multiple sclerosis (MS). However, psychosis as debut of MS is rare and, even in these cases, is often associated with focal neurologic manifestations.

Case report: We present the case of a 33 year-old woman with no prior medical history, nor substance abuse. The patient had been hospitalized twice in psychiatry; first at age 19 by a depressive episode and second 10 years later for behavioral disturbances in the context of a psychotic disorder. Cerebral MRI revealed then demyelinating images, that were no further study due to non compliance with ambulatory follow-up upon hospital discharge. Several days before current hospitalization, in coincidence with her mother suffering an acute myocardial infarction, patient began to present nervousness, emotional lability, incoherent language, insomnia, perplexity, disorganized behavior and delusional ideation. After the start of olanzapine therapy, the patient had worsening evolution. Despite neurological examination was normal, a brain MRI showed multiple lesions in periventricular and corpus callosum white matter, suggesting demyelinating disease. According to the literature, these findings are well correlated with our patient’s psychiatric picture. Due to risk for worsening psychosis corticosteroids were avoided, with clinical improvement after moving to risperidone.

INTRODUCTION: Poor compliance in subjects with schizophrenia has a high prevalence.

METHOD: Subjects included in the study were patients with schizophrenia consecutively admitted in an acute adult psychiatric ward in Santiago de Compostela from 1997 to September 2005.

RESULTS: Of the 308 patients (69% men), with age between 16 and 79 years (x=41.89±13.80 years), 133 were treated only with oral neuroleptics drugs, 149 with conventional depot neuroleptics and 26 with long-acting risperidone. 60.2% patients were hospitalized in one or two occasions in that period of time, but 14.2% in ≥5 occasions. Men had more admissions. 61.8% patients discontinued treatment against medical advice before the admission. Men were treated with more neuroleptic’s dose than women. Patients with depot neuroleptics received more dose to the discharge (1578, 19 mg/day of chlorpromazine vs 1021.58 mg/day in the Consta® group and 814.45 mg/day in the oral group). The average dose of long-acting formulations: 344.33 ± 198.02 mg/day of chlorpromazine (depot group> Consta® group: 1578.19 mg of chlorpromazine per day in the depot group, 1021.58 in the Consta® group and 814.45 in the oral group). Patients who had been hospitalized for a first episode or exacerbation of schizophrenia during maintenance treatment, received more neuroleptic dose than those who had discontinued treatment against medical advice.

CONCLUSION: Oral neuroleptics were the most used, and long-acting formulations, particularly of conventional antipsychotics (depots) were usually reserved for patients with schizophrenia who were at high-risk of noncompliance. Patients treated with depot formulations tended to receive higher doses of neuroleptics than those prescribed oral medication alone.

5. Carlos Gois1, Dr., MD

Introduction: Traumatic brain injury can result in serious and disabling neuropsychiatric disorders.

Case Description: 50 year old, male, single, driver in a fire department. Admitted to the psychiatric ward for acute psychosis and suicidal ideation. At the age of 42, he fell from a fire truck, having a temporal head trauma. Since the accident, he began to “hear voices which made comments and said nasty things”. Sometimes the voices woke him up during the night. Since then, he does not recall a day without verbal hallucinations. Subsequently he became suspicious and interpreted the voices as those of members of his family and colleagues, thinking that they envied and wanted to harm him. At the age of 49 he had a myocardial infarction, after which he became depressive and began suicidal ideation. Several months later, he came to a psychiatric consultation and began treatment for a depressive episode with psychotic features (sertraline and olanzapine). Having shown no response, he was admitted for investigation. The head computed tomography didn’t show any alterations. The electroencephalography (EEG) showed slow bilateral temporal activity. The neuropsychological testing (NT) showed marked memory and mild executive function impairments. The patient improved with olanzapine 20mg/day.

Discussion: This case shows the difficulty of differential diagnosis between late onset schizophrenia and psychosis secondary to traumatic brain injury. Based on the review of cases, we found that in secondary psychosis the most common EEG and NT changes are similar to those we found in this patient.

4. Peishen Bai2

Objective: To evaluate the add-on therapeutic effect of the self-dispense herb formula—Qing Xin Chong Ji-I combined with risperidone and olanzapine in the treatment of schizophrenia and to observe Qing Xin Chong Ji-I effect on reducing side effects of antipsychotics.

Method: All the subjects were diagnosed as schizophrenia according to the DSM-IV-R diagnosis standard and were randomized into 4 groups: the treatment group 1 (Qing Xin Chong Ji-I combined with risperidone or olanzapine) and the control group 1 without Qing Xin Chong Ji-I; the treatment group 2 (Qing Xin Chong Ji-I combined with chlorpromazine, haloperidol or perphenazine) and the control group 2 without Qing Xin Chong Ji-I. The treatment lasted for 8 weeks. The Positive and Negative Syndrome Scale (PANSS) were used to evaluate therapeutic effects, and Treatment Emergent Side effect Scale (TESS) was used to estimate side effects respectively before the treatment and at the 2th, 4th, 6th, 8th weeks after the treatment.

Result: The total scores, the scores of positive syndrome, negative syndrome and general syndrome of PANSS in the treatment group and the control groups were significantly different before and after 8 weeks (P<0.01). It showed that Qing Xin Chong Ji-I could reduce side effects of antipsychotics.

Conclusion: Qing Xin Chong Ji-I has add-on effect for risperidone and olanzapine in the treatment of schizophrenia, especially effective for the positive symptoms of schizophrenia. It can reduce the side effect rates of antipsychotics and has clinical value in the treatment of schizophrenia.

A WALK IN THE PARK: RECOVERY IN SCHIZOPHRENIA / TOURETTE’S

INSTITUTIONS
1. Strategic Health Limited, CCT Services Ltd, Napier, New Zealand

AUTHORS
1. Errol Lloyd Hudson¹, Dr, MBChB, PGDipPG-Otago, lloyd.shl@xtra.co.nz, 2. P. Milne¹, 3. M. Stewart¹

Objective: to rehabilitate a 22 year old Maori male diagnosed with chronic schizophrenia and Tourette’s/OCD. Referred to CCT, at age 21, he was regarded as mute with severe mobility impairments. After 6 months of establishing relationships we discovered his obsession with vampire movies and an enduring passion for rugby. Family contact revealed that he had been a regional rugby representative prior to the onset of his illness at age eleven.

We hypothesised that by using a person-centred methodology, based on and re-introducing his earlier advanced rugby motor skills, we might motivate and assist him towards recovery. The method used to integrate his speech and movement was to reconnect with his prior rugby experience by training with him in a familiar environment, the rugby park, using what we called a W-T-P (Walk, Talk and Pass) intervention. His medications are clozapine, fluoxetine and folic acid.

After 6 months the results have been two-fold. He can talk fluently and describe his experiences coherently. He can walk, participate in community life and has started part-time paid work. Other clients of CCT have participated in similar W-T-P based activities and demonstrated similar gains.

We conclude that W-T-P interventions, (Walk, Talk, Pass), (Walk, Talk, Participate), (Work, Talk, Play) are successful person-centred recovery matrices for people with schizophrenia and Tourette’s/OCD.

15. William G Honer⁷

Objectives: Patients with a single episode of psychosis often expect medication discontinuation after a period of remission. Yet controlled studies regarding medication discontinuation are scarce. This double-blind randomized placebo-controlled study aims to investigate the efficacy of relapse prevention in patients who had maintenance treatment for at least 12 months after a single episode psychosis.

Methods: Following a first/single episode of DSM-IV schizophrenia and related psychosis, patients who were remitted well and on maintenance medication for at least 12 months (mean 22 months) were randomized to receive either maintenance medication (quetiapine 400mg/day) or placebo.

Results: 178 patients were randomized. Relapse rate was 30.3% in the maintenance group and 62.9% in the placebo group (log-rank test, Chi-square=18.99, p<0.001). Significant relapse predictors were patients on placebo (hazard ratio, 0.349; CI, 0.202-0.601), having more pre-morbid schizoid and schizotypal traits (hazard ratio, 3.081; CI, 1.712-5.545), scoring lower in the logical memory test (hazard ratio, 0.913; CI, 0.86-0.969), having more blink rate (hazard ratio, 1.009; CI, 1.002-1.016) and diagnosed with schizophrenia (hazard ratio, 1.816; CI, 1.096-3.008).

Conclusions: New data on relapse risk were identified in remitted first/single episode psychosis patients following an average of 22 months of maintenance medication. Relapse rates even after this period were comparable to that after the first episode. Significantly, about 37% of patients did not relapse with medication discontinuation. The predictors identified could help to further inform the real-life decision regarding medication discontinuation.
It's known that positive and negative symptoms in a first schizophrenic episode haven't a prognostic value, and neither diagnostic or therapeutic variables. It's not clear if premorbid adjustment could conditionate the development of illness in vulnerable people, or could predict diagnose or evolution of schizophrenia. Using a data base of 50 schizophrenic patients, we correlated prepsychotic factors with personality, evolution, social and working environment, previous year stressors, familial psychiatric morbidity, type of onset, schizophrenic symptoms, etc... obtaining these results:

- 88% were single
- 42% depend economically on others
- 44% had previous schizoid personality
- 16% had familial antecedents of schizophrenia
- 42% had a processual evolution course of the illness
- 80% were treatment responders, but in follow up (9.2 years) only 48% were responders
- 12% evolved to deficitual form of the illness

About previous background 6 months before the onset of illness we have found:

- 32% and 24% were adequate in social and familial communication areas respectively. 22% had marked social withdrawal.
- 32% had bizarre hobbies, 20% defined themselves as "weird", 22% shy.
- 12% had school stressors, 6% military service, 8% familial conflicts. 8% changed residence, 4% lost a job or a relative, 6% had school or affective difficulties.
- 52% had no previous stressors.

We can conclude that patients with previous schizoid personality, insidious onset, processual course and poor evolution, seemed to be more vulnerable to the former stressors analysed.

---

Schizophrenia represents one of the major public health problems, having a great social and economy impact. Due to the onset at young ages, the disease interferes both with the completing of the education process as well as with the social and professional training of the individual.

Based on data gathered from specialty literature, in the Research Center from Socola Psychiatry Hospital Iasi, a retrospective study was carried out. We studied the following objectives: 1. The frequency and the type of prodromal symptoms; 2. The interference with educational process and socio-professional activities; 3. The criteria that define the high-risk group for schizophrenia; 4. The time period between the onset of the prodromal symptoms and the diagnostic of schizophrenia.

The research method: the patients filled out a questionnaire with 20 questions regarding the onset of schizophrenia and also was applied the GAF scale.

The results obtained from this study confirmed that: the data from the specialty literature regarding the symptomatologic spectrum of schizophrenia is accurate; the inclusion criteria for high-risk for the development of schizophrenia group, the importance of the time interval between the onset of prodromal symptoms and the diagnostic of schizophrenia, as prognostic factor in the later outcome of the disorder.

Conclusion: the early recognition should allow as many persons with high-risk for the developing of psychosis as possible to benefit from the early adequate treatment initiation.

3. Felicia F. Romosan, Dr., MD, PhD, romosan.felicia@yahoo.com
4. Cristina C. Bredicean, Dr., MD, cristinabredicean@yahoo.com

Aim: The aim of this study is to evaluate the clinical and functional characteristics of a 5 year follow up of first episode psychosis admitted in the Psychiatric Clinic Timisoara in the year 2003.

Method: A total of 35 first episode psychosis patients including, have been studied. Participants baseline demographic, clinical and functional characteristics and described, during the follow up period they have been assessed the psychotic process, dynamic with all diagnosis changes, and the important modifications in socio-professional and family functioning. An actually (2008) clinical and functional evaluation has also been made using standardized instruments (BPRS, GAF).

Results: At baseline only 16% of cases have the diagnosis of schizophrenia, whereas the full range of psychotic disorders are represented. Over time only 47% of the cases remain on a stable diagnosis most of them from the schizophrenia diagnosis. The cumulative first relapse rate at 5 years initial recovery was 78%. Declines in functioning are present in most of the cases.

Conclusions: Clinical and functional changes are a common feature for the first episode psychosis. Improving life standards of these patients relates for the future to a more detailed analyse of the psychotic dynamic process.

The essentials should be some case reports with exact data of more precise etiological diagnostic in some Sch-like psychotic disorders.

The dominant approach are the etiopatogenetic approach and detection of: infective, toxic, metabolic, endocrinological, neurological, vascular, anatomic, real genetic, iatrogenic, and other well known causes of disturbances of CNS functions.

The second dominant approach is the targeted pharmaco- and psycho-pharmacotherapy not only the biochemical consequences, but the treatment of real causes of psychotic disturbances, too (infecitive-parainfective, inflammatory-immunologic, metabolic, toxic, endocrinologic, neurogenic, cerebrovascular, iatrogenic, ect.).

THE ROLE OF ABSTRACT REASONING IN EMOTIONAL PROCESSING IN SCHIZOPHRENIA

INSTITUTIONS
1. Psychiatric Clinic, Clinical Psychology and Psychophysiology, Munich, Germany
2. Institute for Psychiatry, Biological Psychiatry, Belgrade, Serbia and Montenegro

AUTHORS
1. Lana Marija Ilankovic1, Mrs., MSc, lanam2004@yahoo.com
2. Nikola N Ilankovic2, Prof. Dr., PhD, ilankov@beotel.yu
3. Kristina Fast1, Mrs, PhD, kristina.fast@med.uni-muenchen.de

Aims/Objectives
Most of the studies investigating emotional processing in schizophrenia have used facial affect recognition paradigms1,2, whereas we introduced a cognitive task that requires more complex social and emotional judgments. We are interested in how the ability to compare and match stimuli of different emotional valence is related to symptomatology of the disorder and cognitive abilities in schizophrenic patients.

Methods
15 patients with schizophrenia and 15 control subjects were shown two pictures simultaneously, with negative, positive or neutral emotional content. They were asked to match the pictures according to their valence and then performed surprise recognition memory test. In addition, several neuropsychological tests were administered.

Results
The group of patients was significantly less accurate than the group of controls, when positive or neutral pictures were combined with pictures of negative valence. The patients performed significantly worse in recognizing the novel picture combinations across all the combination categories. The group of patients had significantly lower scores on Halstead Category Test and Similarities (HAWie-R).

Conclusions
The patients exhibited a negative bias when evaluating incongruent picture pairs, especially those containing neutral pictures, that are more flexible for interpretations3. The tendency to make false recognitions of novel picture combinations might be due to the failure to use semantic structure embedded in the link between two visual materials. Additionally, as patients have shown impaired abstract-flexibility and concept learning, it may be the case that not only impaired affect recognition, but also deficits in abstract reasoning, may lead to delusions and misinterpreting banal events as significant.

STUDY OF SUGGESTIBILITY IN PERSONS WITH SCHIZOPHRENIA

INSTITUTIONS
1. Georgian Association of Mental Health, Psycho-social Rehabilitation Center, Tbilisi, Georgia
2. Psycho-neurological Dispensary, Tbilisi, Georgia

AUTHORS
1. Temur T. Iosebadze1, Dr, PhD, tiosebadze@mail.ru
2. Nino D. Dzagania2, Mrs, tiosebadze@mail.ru

Aim: Study of suggestibility in persons with schizophrenia.

Target groups: The experimental group was formed out of 56 users (36 females and 20 males) of our Psycho-social Rehabilitation Center. Their age varied from 18 to 68. The control group was composed of 37 students of a Psychological faculty (30 females and 7 males). Their age fluctuated from 18 to 24.

Method: As a method of study we used Barber’s Creative Imagination Scale. To subjects of the experimental group this method was applied from 2 to 5 times, during 6 months.

Main results: In the experimental group the subjects have been distributed in the following way: (0) lack of suggestibility - 12.68%; (1) weak of suggestibility - 20.56%; (2) average of suggestibility - 13.8%; (3) high of suggestibility - 24.51%; (4) very high of suggestibility - 28.45%. In the control group we have obtained the following percentage distribution of subjects: (0) lack of suggestibility - 6.76%; (1) weak of suggestibility - 17.18%; (2) average of suggestibility - 22.25%; (3) high of suggestibility - 27.89%; (4) very high of suggestibility - 25.92%. We also have studied changeableness of suggestibility during 6 months in the experimental group: invariable indices of suggestibility were shown by 27.95% of subjects; slight changeableness was obtained in 37.26% of subjects; considerable change was 26.09% of subjects; and radical change was obtained in 8.7% of subjects.

2. S. Strkalj Ivezic2, Dr, PhD, sladjana.ivezic@bolnica-vrapce.hr
3. M. Kusan Jukic3, Dr, MD, mkusan69@yahoo.com

OBJECTIVES: To study the influence of antipsychotic therapy type in relation to social functioning. The study was designed to examine connection between social functioning and antipsychotics in a group of schizophrenic patients, also according to the gender, education and duration of illness.

METHODS: Patients (N=123), living in supportive accommodation, with diagnosed schizophrenia according to ICD 10 criteria were included in the investigation. 31.7% of patients, 26 females and 13 males, were on atypicals (olanzapine, risperidone, clozapine). The Social Functioning Scale according to Bellack has been used for the assessment of social functioning in the study. We used the descriptive analysis, regression analysis, discriminatively analysis and group of centroids for statistical evaluation of data.

RESULTS: There is no difference in social functioning between patients on atypicals and patients treated by typical antipsychotics. Results have shown the better social functioning of women in compare to males. Also, the education and duration of illness were not in relation to social function.

CONCLUSIONS: Although there were not difference in social functioning in two groups of patients treated by different type of antipsychotics, we observed a positive trend of better social functioning in group of patients who takes atypicals. The importance of that positive trend has to be checked in larger sample of patients to make further conclusions. The better social functioning of women was in concordance with the results of other investigators.

Aims: This study examined the three attentional networks: alertness, orienting and executive control in a group of young schizophrenic patients mainly treated with stable dosage of Neuroleptics, with recent onset of the disease.

Methods: 27 patients with schizophrenia (PS) are matched for age and years of study to 27 healthy controls(C).

An adapted version of the Attentional Network Task (ANT-I) was used, which explores simultaneously and independently the attentional networks particularly alerting (sound vs no sound), orienting (valid, invalid or no visual cues) and executive system (through the sensitivity to conflictual stimuli with congruent vs. incongruent visual flankers).

RESULTS: PS compared to C displayed a greater alerting effect (F[1,52]=11.4; p=0.001), had a longer overall reaction time (RT) (F[1,52]=2.93; p=0.09). Concerning orientation, the group of PS showed a difficulty to detect contrast between valid and invalid cue (F [2,104]=6.2; p=0.003).

Conclusion: Our study confirms recent findings about a relative preservation of reactivity to an alerting cue and of the Executive Control Network in schizophrenia. In addition, Neuroleptics would not have a deleterious effect on these attentional networks.

7. Karim Tabbane, Dr., k_tabbane@yahoo.fr

OBJECTIVES
The aim of the present work was to develop a scale to evaluate the subjective experience of cognitive dysfunction of patients with schizophrenia and to conduct a validation study of the scale.

METHODS
The authors constructed the Self-Assessment Scale of Cognitive Complaints in Schizophrenia (SASCCS) based on a questionnaire covering several cognitive domains: memory, attention, executive functions, language and praxia. The SASCCS is a 21-item, Likert-type scale which is easy and simple to use. This scale was inspired by the Subjective Scale to Investigate Cognition in Schizophrenia (1) and was established based on the cultural and linguistic context of Tunisia.

We planned to evaluate the psychometric properties of the SASCCS in a population of 105 Tunisian Arabic dialect-speaking outpatients meeting the DSM-IV diagnostic criteria for schizophrenia or schizoaffective disorder. Patients were assessed by the Positive and Negative Syndrome Scale, the Calgary Depression Scale and the Global Assessment of Functioning Scale. Cognition was evaluated by a neuropsychological battery.

RESULTS
Preliminary analyses on 60 patients showed a good internal consistency for the global score (alpha de Cronbach = 0.83). Validity of the internal structure was evaluated through a principal component analysis which identified seven factors that accounted for 66.6% of the total variance.

CONCLUSION
We present a work in progress: Validation of the SASCCS will be completed through an enlargement of the sample and an exploration of the pattern of correlation between subjective scores and objective cognitive assessment.

2. Nikola Ilankovic, Prof.
3. Veronika Bojic, Dr.
4. Ivana Leposavic, Phd

Tuberous sclerosis complex (TSC) is an autosomal dominant neurocutaneous disorder resulting in multisystemic hamartomatous lesions, diagnosed mostly in childhood. The clinical findings and severity of TSC are highly variable.

Objectives/methods: presenting a case of TSC associated with seizures and paranoid psychotic episode, diagnosed at the adult period of life.

Results: patient (39), having seizures from the age of 7, was admitted because of more frequent seizing, anxiety and hypertension. Seizures were partial and partial with secondary generalization. One year prior to admission, patient experienced a paranoid psychotic episode treated successfully with small doses of flufenazine. During somatic examination typical skin lesions were found (facial angiofibromas, hypomelanotic maculas, Shagreen patches). TSC was definitely diagnosed after extensive exploration (blood analysis, EEG, internist, dermatologist, ophthalmologist, pulmonal roentgen, cranial CT and MRI, cardial and abdominal ultrasonography, psychological exploration). Typical cortical and subcortical nodules in brain, renal and hepatic, cystic and nodular formations were found. Psychological examination showed subnormal intelligence. With combined anticonvulsive therapy (carbamazepine, phenobarbiton, diazepam) better control over seizures was attained.

Conclusions: Earlier diagnosis of TSC leads to better prognosis. Detecting obvious cutaneous stigmata is useful in suspecing of TSC in adult patients with seizures and subnormal intelligence. Psychotic episodes are rarely reported complications of TSC. This case is a reminder for neuropsychiatric complications of neurocutaneous genetic disorders.

6. Nikolaos Smyrnios, Dr., MD

Eye movement dysfunction (EMD) has been considered a candidate neurophysiological marker for the study of genetic liability in schizophrenia. In this respect it is crucial to confirm a trait versus state dependence of these measures. Twenty patients with DSM IV schizophrenia were assessed using a battery of oculomotor tasks in the acute phase of their disorder without being treated with antipsychotic medication and then again in a remission phase under treatment with antipsychotic medication. The saccade latency in the saccade task, the error rate and antisaccade latency in the antisaccade task, and the frequency of unwanted saccades in the active fixation task were stable in time both in the group level and within each individual, showing no relation to the significant improvement in different psychopathological dimensions of these patients. The root mean square error, gain and saccade frequency in the pursuit task were not stable over time although again this instability was not related to the changes in psychopathological status of these patients. Finally the saccade frequency in the active fixation task with distractors was not stable in time and was sensitive to changes in specific dimensions of psychopathology.

Aims: Some patients with schizophrenia switch medications due to lack of efficacy or intolerable side effects; improvement in symptoms and side effects following a switch must be assessed.

Methods: In a 12-week, open-label, baseline-controlled, flexible-dose switch study, adult outpatients with schizophrenia experiencing suboptimal efficacy or tolerability issues were switched from haloperidol (n = 99), olanzapine (n = 82), or risperidone (n = 104) to ziprasidone (80-160 mg/d; dosed twice daily with food). The primary efficacy evaluation was BPRS score at week 12. Safety evaluations included change from baseline in movement disorders (SAS, BAS, AIMs) body weight, prolactin, and fasting lipids levels. Statistical tests were 1-sided, noninferiority comparisons with correction for multiple comparisons (0.025/3 significance level), for primary efficacy end point, or 2-sided (0.05 significance level), for secondary end points.

Results: BPRS scores improved significantly compared with all 3 preswitch medications at week 12. Mean change from baseline (SD) for patients switched from haloperidol, olanzapine, or risperidone was -11.3 (16.3), -6.3 (14.2), and -9.9 (13.2), respectively (p < 0.0001 vs baseline). Movement disorders, measured by SAS, BAS, and AIMs, improved significantly for subjects switched from haloperidol or risperidone. Change in weight (kg ± SD) from baseline was 0.4 ± 3.97, -2.0 ± 3.99 (p < 0.001), and -0.6 ± 3.21, respectively.

Conclusions: Patients switched to ziprasidone demonstrated improvement in symptoms and movement disorders, with a neutral weight effect. Ziprasidone is an appropriate switch option for patients experiencing suboptimal efficacy or poor tolerability with their current treatment.

ASSESSMENT OF DYSFUNCTIONAL WORKING MODELS OF SELF AND OTHERS IN SCHIZOPHRENIC INPATIENTS

INSTITUTIONS
1. Institute of Psychiatry & Neurology, III Department of Psychiatry, Warsaw, Poland

AUTHORS
1. Kama Katarasinska-Pierzgalska, Mrs, MD, kamyki@ipin.edu.pl
2. Agnieszka Szaniawska-Bartnicka, Mrs, MD
3. Anita Młodozeniec, Mrs, MD
4. Małgorzata Jedrasik-Styla, Mrs
5. Agata Jarek, Mrs, MD
6. Tomasz Szafrański, Mrs, MD, PhD

Objectives:
Dysfunctional cognitive schemata may influence individual vulnerability to schizophrenia. To measure dysfunctional working models of self and others Dysfunctional Working Models Scale (DWM-S) was developed by Perris and collaborators. The aim of the study was to assess the dysfunctional working models of self in schizophrenic inpatients.

Methods:
Sixty inpatients with schizophrenia or schizoaffective disorders were rated with PANSS, Calgary Depression Scale, Hamilton Anxiety Rating Scale and InterSePT Scale for Suicidal Thinking. Patients completed self-report questionnaire DWM-S as well as State-Trait Anxiety Inventory. In addition forty inpatients with depression and anxiety disorders completed DWM-S.

Results:
The mean age of the patients was 36.1 ± 14.8 years, they had mean 13 ± 3.5 years of education. The mean duration of illness was 8.7 ± 9.2 years. Mean DWM-S score was 125 ± 34.5. We found positive correlation of DWM-S score with total PANSS score (Spearman R = 0.41, p<0.01) but there were no significant correlations with depression or anxiety measures. Scores of DWM-S in schizophrenic patients were significantly higher than scores among patients with depression or anxiety disorders (117 ± 25.6 and 114 ± 28.9; p<0.05)

Conclusions:
The level of dysfunctionality of cognitive schemata was not influenced by: age, sex, education, and duration of schizophrenic illness. There was positive correlation of the level of dysfunctionality of cognitive schemata and severity of schizophrenia symptoms but not with any particular schizophrenic symptom dimension. Symptoms of anxiety or depression did not influence the DWM-S score.

EFFECT OF ZIPRASIDONE DOSE ON ALL-CAUSE DISCONTINUATION IN SCHIZOPHRENIA

INSTITUTIONS
1. Pfizer Inc., New York, New York, United States
2. Nathan S. Kline Institute for Psychiatric Research and New York University School of Medicine, Orangeburg, New York, United States

AUTHORS
1. Onur Kayaral, Dr., MD, MPH
2. Leslie Citrome, Dr, MD, PhD
3. Ruoyong Yang, Dr., PhD
4. James Harnett, PharmD, MS
5. Paul Glue, Dr., MD, PhD

Aims: To examine the relationship between ziprasidone dose and all-cause discontinuation in patients with acute exacerbation of schizophrenia or schizoaffective disorder.

Methods: Data were analyzed for the first 28 days from 4 pivotal, randomized, double-blind, fixed-dose trials of patients with schizophrenia or schizoaffective disorder receiving ziprasidone (40-160 mg/day dosed with food) to examine the association between ziprasidone dose and all-cause discontinuation due to lack of efficacy and/or adverse events, relative to placebo. Differences in discontinuation were evaluated using Cox proportional hazard models and number needed to treat (NNT).

Results: Overall all-cause discontinuation for ziprasidone ranged from 26.9% for 160 mg/d to 40.9% for 40 mg/d compared with 49.5% for placebo. The NNT for avoiding 1 additional all-cause discontinuation compared with placebo were 12 (40 mg/d, n = 186), 25 (80 mg/d, n = 154), 9 (120 mg/d, n = 125), and 4 (160 mg/d, n = 104). Ziprasidone 120 mg/d and 160 mg/d were associated with significantly lower all-cause discontinuation rates vs placebo (p<0.05); 160 mg/d was associated with a significantly lower all-cause discontinuation rate vs lower-dose ziprasidone (40-80 mg/d, p < 0.05). Lack of efficacy accounted for 51% of all medication discontinuations across ziprasidone groups, compared with 62% for placebo. Findings for overall discontinuation due to lack of efficacy are consistent with results for all-cause discontinuation.

Conclusions: Consistent with previous reports, higher doses of ziprasidone (120-160 mg/d) are associated with significantly lower all-cause discontinuation rates and more favorable NNT vs placebo.

**AWARENESS, ATtribution OF SYMPTOMS AND EXECUTIVE FUNCTION IN SCHIZOPHRENIA**

**INSTITUTIONS**
1. VA Puget Sound Health Care System, American Lake Div., Mental Health Service, Tacoma, United States
2. University of Washington, School of Medicine, Dept. of Psychiatry and Behavioral Sciences, Seattle, United States

**AUTHORS**
1. Nael Kilzieh1,2, Dr., MD
2. Amanda E. Wood1,2, PhD
3. Annette Kennedy1
4. Andre Tapp1,2, MD

**Objective:** Awareness of illness in schizophrenia is a complex multi-dimensional function which includes awareness of symptoms and attributing them to mental illness. We aimed to study the correlation of these two dimensions to executive function.

**Methods:**
Stable outpatients diagnosed with schizophrenia or schizoaffective disorder were assessed (n= 21). Executive function assessment included Wisconsin Card Sorting Test (WCST) completed categories (CC) and perseverative errors (PE), stroop color/word interference task, and semantic and phonologic verbal fluency (VF). Additionally, we assessed premorbid IQ utilizing the Wide Range Achievement Test. Awareness and attribution of positive and negative symptoms was assessed utilizing the Scale to assess Unawareness of Mental Disorders (SUMD). We report the results of linear correlations.

**Results:**
Awareness of positive symptoms correlated with better semantic VF (r=-.63, p=.005). Awareness of negative symptoms correlated with better performance on the WCST-PE (r=.48, p=.03) and stroop (r=.69, p=.02). Correct attribution of positive symptoms correlated with better performance on the WCST-CC (r=-.75, p=.003), WCST-PE (r=.56, p=.05), and semantic VF (r=-.6, p=.03). Correct attribution of negative symptoms correlated with better performance on the WCST-CC (r=-.5, p=.03) and semantic VF (r=-.46, p=.05). Symptoms awareness and attribution did not correlate with premorbid IQ.

**Conclusion:** Awareness and attribution of positive and negative symptoms are significantly correlated with executive function. Attribution of symptoms maybe more closely linked to executive function.

**CLINICAL, PSYCHOLOGICAL FACTORS OF POSTSCHIZOPHRENIA DEPRESSION**

**INSTITUTIONS**
1. Kyrgyz State Medical Academy, Clinical psychology and psychiatry, Bishkek, Kyrgyzstan

**AUTHORS**
1. Alexander Stanislavovich Kim1, Dr., MD, PhD, psyalex@mail.ru

**Objectives:**
1. To identify a phenomenon of loneliness, levels of depression and anxiety of patients schizophrenia disorders.
2. To allocate the role of the phenomenon of loneliness as the differentiation factor of therapy of patients with postschizophrenia depressions.

**Material and methods:**
85 patients were surveyed at the Republican centre of mental health in Bishkek city in the age of from 18 till 60 years with schizophrenia disorders, modified UCLA scale for the evaluation of the level of the loneliness, Standardized scales of the evaluate depressions and anxiety.

**Results:**
Patients with schizopformes disorders (control group) 32 people had less level of loneliness (39.8 (P<0.01)) in comparison with patients suffered from, schizophrenia (paranoic) (62.3 (P<0.01)). While the intensity of hypnomic affect of patients with deep psychopathological disorders was higher (58.2 (P<0.01)), then one of patients with schizophrenia. Anxious level was middle and there wasn’t found any verified differences.

**Conclusions:**
Phenomenon of loneliness is one of the clinical and psychological mechanisms causing development of postschizophrenia depressions. Phenomenon of loneliness is one of components of differential therapy of patients with deep psychopathological disorders.

WELLNESS PROGRAM: A PROGRAM FOR MANAGING WEIGHT CONTROL IN SCHIZOPHRENIA: EXPERIENCES FROM THE CZECH REPUBLIC

INSTITUTIONS
1. Charles University, 1st Medical Faculty, Prague, Psychiatry, Prague, Czech Republic
2. Charles University, 3rd Medical Faculty and Prague Psychiatric Center, Psychiatry, Prague, Czech Republic

AUTHORS
1. Eva Kitzelová, Dr., PhD, ekitzelova@centrum.cz
2. Lucie Motlova, Dr, PhD, motlova@pcp.lf3.cuni.cz
3. Eva Dragomirecka, Dr., dragomirecka@pcp.lf3.cuni.cz

Objective: Wellness Program was implemented in January 2005 in the Czech Republic. We present the outcomes of 500 out-patients evaluated since January 2005 to May 2007.

Methods: This program was delivered by trained psychiatric nurses in 10 sessions lasting one-hour, with the first eight sessions held weekly and the last two held monthly in consecutive groups consisting of 5-8 participants. We evaluated the influence of participation in this program on weight control. Weight and knowledge about nutrition and exercise were evaluated at the baseline and at the end of the program for both groups.

Results: Between January 2005 and May 2007 732 out-patients with schizophrenia-spectrum diagnoses entered the courses of the Wellness Program consecutively in the centers throughout the Czech Republic. For the analysis we included only those patients who participated at least 7x (N=500). Knowledge about a healthy lifestyle was significantly improved by the end of program (tests about nutrition - 65% of answers were correct in the baseline, 79% by the end; tests about exercise - 68% at the baseline, 80% correct answers at the end). The participants were able to remember the facts about nutrition and exercise and were also able to use them in real life which was connected to their weight loss.

Conclusions: The Wellness Program was successfully accepted by the patients and it is popular. It leads to the improvement of the health of schizophrenic patients, decreases or keeps the body weight down and prevents social isolation and destigmatization.

RESPONSE TO INTRAMUSCULAR ZIPRASIDONE AS A PREDICTOR OF RESPONSE TO ORAL ZIPRASIDONE

INSTITUTIONS
1. Pfizer Inc., New York, United States
2. University of Colorado Health Sciences Center, Department of Psychiatry, Denver, United States
3. Pfizer GmbH, Karlsruhe, Germany

AUTHORS
1. Francine Mandel, Dr., PhD
2. Michael Allen, Dr., MD
3. Stefan Kolb, Dr., MD
4. Ilise Lombardo, Dr., MD

Aims: To determine the ability of an early response to intramuscular (IM) ziprasidone to predict the 6-week response to oral ziprasidone. Methods: In a 6-week, multicenter, single-blind, randomized, flexible-dose study, patients with schizophrenia or schizoaffective disorder received IM ziprasidone ≤ 40 mg/d followed by oral ziprasidone 80-160 mg/d (n = 429) or IM haloperidol ≤10 mg/d followed by oral haloperidol 5-20 mg/d (n = 138); IM period was ≤ 2 days. We calculated the percentage of IM responders (≥ 20% change in BPRS score from baseline to last IM) who were oral responders (≥ 30% change in BPRS score from baseline to last observation in the oral phase).

Results: In total, 235 of 429 (54.8%) ziprasidone subjects and 77 of 138 (55.8%) haloperidol subjects responded to treatment at 6 weeks. 90 ziprasidone subjects (20.9%) were responders to IM treatment. Of these, 65 (72.2%) were oral responders at last observation (sensitivity, 27.7%; specificity, 87.1%). 17 haloperidol subjects (12.3%) were responders to IM treatment and 12 (70.6%) were responders at last observation (sensitivity, 15.6%; specificity, 91.8%). While there was no significant difference between the treatment groups (p = 0.55), there was a significant difference between the IM responders and nonresponders (p < 0.0001) with regard to prediction of oral phase response.

Conclusion: Response to IM treatment is a significant predictor of an oral response, supporting the clinical practice of continuing patients on the oral medication received in IM form.

SCHIZOPHRENIA AND LIVER DYSFUNCTION CAUSED BY PORTACAVAL SHUNTING

INSTITUTIONS
1. Hafnia Unit of Clinical Biochemistry, Denmark

AUTHORS
1. Jens Krøll, Dr., MD PhD, krollj@danbbs.dk

The hypothesis is presented that a dysfunction of the liver, caused by portacaval bypass of a normal liver, is a predisposing factor in the pathogenesis of schizophrenia. In support of this hypothesis evidence is presented, showing a more than coincidental correlation of deviant biological findings in schizophrenia and cases of portacaval shunting. Thus, correlated deviations are observed in the expression of neurotransmitters and neuroreceptors, metabolic parameters, immune response and stress parameters as well as signs of neurotoxicity with cerebral atrophy. Doppler sonographic investigations of the portal venous system should enable a non-invasive test of the hypothesis.

2. Adam Klasik, Mr., PhD, krysta@mp.pl
3. Irena Krupka-Matuszczyk, Prof.
4. Jacek Przybyło, Dr.

Aim: Different levels of cognitive functioning in schizophrenic patients may be linked to heterogeneity of this disease. In some studies there were described groups of schizophrenics with IQ within normal limits, and no cognitive deficits measured with tests like WCST were found in them. According to some authors, 25% of subjects suffering from schizophrenia are those, who present either mild or no cognitive deficits at all. Described here are three cases of schizophrenic patients showing no deficits measured by neuropsychological tests.

Methods: A Vienna Test System was used to measure working memory (CORSI Test), attention (COGNITRON Test), and reaction time (RT Test). All three examinees patients were female, aged between 21 and 25 years. Their level of social functioning was relatively good, two of them were students, one of them already graduated from the university. They experienced periodic exacerbations of positive symptoms, which did not have a high impact on their quality of life.

Results: In each of the above patients no deficits were found in the examinations with applied neuropsychological tests.

Conclusions: These results confirm the existence of “cognitively preserved” schizophrenic subjects. Further studies on larger groups should be done to describe this phenomenon. The results of these studies could be useful in the process of including cognitive functioning into the diagnostic criteria of schizophrenia. An interesting observation is, that all three described subjects were female, as it is known that there are differences in social functioning in schizophrenia between men and women.

5. Eva Ceskova1, Dr., MD, PhD, eceska@med.muni.cz

Background: The potential of influencing individual parameters of cognitive deficit in depression by rtMs has not been explored in detail yet.

Methods: The group was formed by 20 men. Parameters of the stimulation: intensity of the stimulation 110% of motoric threshold, frequency of the stimulation (15 Hz), continuation of the pulse set (10 sec.), interspace among the sequences (30 sec.) and total number of the applied stimuli (1500), length 3 weeks. Patients were examined by the set of neuropsychological tests, the interval test - retests was 4 weeks.

Results: We found out statistically significant improvement in the part of A of TMT, in VFT, in all index numbers of WMS and in categories of perseverative errors and responses in WCST. In other tests there were not any increase of the achievement statistically significant. Only in the CPT there appeared by some patients moderate decrease of the achievement.

Conclusion: With regard to number of examined patients we can not generalize our findings though we can regard this research as a benefit for the exploration of the problematics of positive, procognitive effect of rtMs.

SOCIAL AND PHYSICAL ANHEDONIA IN HEALTHY SIBLINGS OF SCHIZOPHRENIA PATIENTS COMPARED WITH POPULATION BASED CONTROL SUBJECTS

INSTITUTIONS
1. National Public Health Institute, Mental Health and Alcohol Research, Helsinki, Finland
2. University of Helsinki, Department of Psychology, Helsinki, Finland
3. University of Helsinki, Department of Psychiatry, Helsinki, Finland

AUTHORS
1. Annamaria Kuha1,2, M. Psych
2. Annamari Tuulio-Henriksson1,2, PhD
3. Jaana Suvisaari1,3, MD, PhD
4. Jouko Lönqvist1,3, MD, PhD

Anhedonia, a reduced ability to experience pleasure, is one of the main symptoms of schizophrenia. Especially physical anhedonia may be an endophenotypic marker for schizophrenia, but the results have been conflicting (Kendler et al 1996). We set out to study whether well siblings of schizophrenia patients have elevated levels of social and physical anhedonia compared with controls in a population based study design.

Physical and social anhedonia scores (measured with the Social and Physical Anhedonia Scales) were compared in siblings with schizophrenia spectrum disorder (n = 91), their healthy (n = 75) and nonpsychotic siblings (n = 30), and control subjects (n = 67) with no personal or family history of psychotic disorder. All the study groups were from population based study samples. The scale scores between the groups were compared using analysis of covariance, with age and gender as covariates.

We found no statistically significant differences between nonpsychotic and healthy siblings and controls in levels of anhedonia. However, the ill siblings with schizophrenia spectrum disorder had significantly elevated anhedonia compared to all other groups.

The results suggest that social and physical anhedonia, as group level, do not differentiate subject with elevated vulnerability to schizophrenia from population controls.

**TO INVESTIGATE GENETIC PROFILE OF SCHIZOPHRENIC PATIENTS IN PAKISTAN**

**INSTITUTIONS**
1. Dr Panjawni Centre for Molecular Medicine and Drug Research, Laboratory Department, Karachi, Pakistan

**AUTHORS**
1. Deepak Kumar¹, Dr, deepak_gangaramani@hotmail.com

**AIMS:** To study the association of SNPs markers with known genes (DYNRBP1 and NRG1), estimation of D-serine (serine racemase) in the urine samples of schizophrenic patients and control, metal analysis from blood samples, isolation of serine racemase enzyme from human serum and biostatistical analysis by using of SNP Alysse for quantitative comparison between controls and schizophrenic patients.

**METHOD:**
- a) DNA extraction from blood sample.
- b) PCR amplification.
- c) Agarose Gel electrophoresis.
- d) Isolation of serine racemase enzyme from serum.
- e) Metal analysis from blood sample.

**RESULTS:** As it is a 3 years project started in 2007 there are no results yet.

**DISCUSSION:** In previous studies to identify the genes predisposing for Schizophrenia and on the basis of twins and adoption studies it has been concluded that neurogenetic components in combinations with environmental factors play very significant role in the etiology of this disease. In this project we are planning to perform gene screening analysis in the Pakistani populations. In addition blood samples are going to be collected from single affected patients (patient with only one parent as carrier or sufferer) along with their parents.

**CONCLUSION:** Conclusions will be made after the completion of the project.

**CHANGES IN THE FUNCTIONAL PSYCHOSIS’ CLINICAL PICTURE AFTER 10 YEARS COURSE**

**INSTITUTIONS**
1. Clinic County Hospital Timisoara No.1, Psychiatric Clinic Eduard Pamfil Timisoara, Timisoara, Romania

**AUTHORS**
1. Mircea D. Lazarescu¹, Prof., MD, PhD, mlazarescu39@yahoo.com
2. Jeni B. Blajovan¹, Mrs., asocpsi@yahoo.com
3. Monica I. Ianciu¹, Dr., MD, PhD, ianciu.monica@yahoo.com

By analyzing the functional psychosis cases recorded in a Case Register, on which yearly assessments have been performed, significant changes in the cases' diagnostic after 5, 10 and even 15 years since onset could be detected. In the TPFEP = (Timisoara Project concerning the Typology and Evolution of Functional Psychosis), in Timisoara (Romania) have been recorded all new cases of functional psychosis in the area, diagnosed according to the ICD-10 and ICD-10 criteria (using the PSE-9 and PSE-10 SCAN assessment instruments). The 10 years summary (performed in 1999, on 456 cases still in evidence from the 774 recorded cases) and the 20 years summary (performed in 207, on 756 cases in evidence from the 1720 cases recorded) show that: the diagnostic is relatively stable after 2 years of evolution, but not before; after 5 years of evolution, there is a certain stability present, but the swing between a diagnostic of persistent delusional psychosis, schizophrenia, schizoaffective disorder and bipolar disorder is still present at 25% of the cases, and at 10% of the cases after a 10 years evolution. The most instable is the short delusional psychosis disorder diagnostic that can change into anything, but most frequently into a diagnostic of bipolar disorder.

SCHIZOPHRENIA AND PERSISTENT DELUSIONAL DISORDER AS DISTINCT PATHOLOGY

INSTITUTIONS
1. Clinic County Hospital Timisoara No.1, Psychiatric Clinic Eduard Pamfil Timisoara, Timisoara, Romania
2. University of Medicine and Pharmacy, Psychiatry, Timisoara, Romania

AUTHORS
1. Mircea D. Lazarescu¹, Prof., MD, PhD, mlazarescu39@yahoo.com
2. Jeni B. Blajovan¹, Mrs., asocpsi@yahoo.com
3. Ion P. Papava², Dr., MD, asocpsi@yahoo.com

In the Timisoara Project concerning the Typology and Evolution of Functional Psychosis (TPTEFP), in which all regional cases of functional psychosis occurring in Timisoara (Romania) during 1985-2004 were recorded and yearly assessed, at the 2007 evaluation 756 cases were analyzed (of the total 1720 cases recorded). 50 cases of persistent delusional psychosis (according to the ICD-10 criteria for research) that maintained diagnostic for longer than 5 years have been identified. The characteristics mentioned in the ICD-10 criteria for this diagnostic were confirmed: adult age, paranoid delusion focused on specific persons, few (mostly auditory) hallucinations present, the concomitant presence of depression, a relatively good social insertion. These cases were compared with 50 cases of schizophrenia and 50 cases that impertinently presented also first grade K.Schneider type symptoms. The research results support the distinction between persistent delusional disorder and paranoia (= single theme centered, organized delusion) and schizophrenia. This clinical entity needs to be closer examined by researchers.

P-03-257

THE IRREVERSIBLE TRANSITION FROM SCHIZOPHRENIA TO BIPOLAR DISORDER AFTER A 5 YEARS EVOLUTION

INSTITUTIONS
1. Clinic County Hospital Timisoara No.1, Psychiatric Clinic Eduard Pamfil Timisoara, Timisoara, Romania
2. University of Medicine and Pharmacy, Psychiatry, Timisoara, Romania

AUTHORS
1. Mircea D. Lazarescu¹, Prof., MD, PhD, mlazarescu39@yahoo.com
2. Jeni B. Blajovan¹, Mrs., asocpsi@yahoo.com
3. Cristina B. Bredicean², Dr., MD, asocpsi@yahoo.com

In the Timisoara Project concerning the Typology and Evolution of Functional Psychosis (TPTEFP), in which all regional cases of functional psychosis occurring in Timisoara (Romania) during 1985-2004 were recorded and yearly assessed at the 2007 evaluation 756 cases were analyzed (of the total 1720 cases recorded). The analysis revealed 37 cases with a diagnostic of schizophrenia or delusional psychosis at onset and during the first 3 years of evolution that have later changed course to bipolar disorder, a diagnostic that has than been maintained for the next 5-10 years of evolution. Schizoaffective episodes have been present during the transition period. Cases of this type should be included in multicenter studies, as these cases, as well as the cases with schizoaffective disorder, imply special problems for the etiopathogenetic and therapeutic research.

Objective: Since depressive symptoms are prevalent, under-recognized and important problems in schizophrenia, this study aimed to investigate prevalence and factors of depressive symptoms in schizophrenics and compare those of inpatient schizophrenics with those of outpatient schizophrenics.

Methods: We studied 177 schizophrenic patients including 87 outpatients and 90 inpatients and performed BDI, ZDS, CDSS, HRSD, PANS, KISP, ESRS.

Results: Depressive symptoms were common. 16.4% of patients had HRSD score of 18 or more. 28.2% of patient had CDSS score of 8 or more. With CDSS, 15.6% of inpatient and 41.4% of outpatient showed significant depression. Lower level of education, being unemployed, shorter duration of illness, residual, paranoid type and GAF score 50-59 group were more depressed. Depression scores by gender, age, religion, duration of illness and suicidal history were different between inpatient and outpatient schizophrenics. Old female outpatients and young male inpatients should be evaluated and monitored for depression.

Conclusion: Severity of depressive symptoms was correlated with positive symptoms and level of insight but not with negative symptoms or extrapyramidal symptoms. Control of positive symptoms is important to improve depression and quality of life of schizophrenics. It is necessary to give more attention to depressive symptoms in patients with high level of insight.

6. Janhavi Vaingankar, MSc, 7. Siow Ann Chong, A/Prof, MBBS, M.Med, FAMS

Aim: This naturalistic and prospective study aims to compare the relative effectiveness between haloperidol, olanzapine, risperidone, and trifluperazine, in patients with first-episode schizophrenia-spectrum disorders.

Methods: Total of 275 patients participated in this study of 18 months duration; 79 on haloperidol, 14 on olanzapine, 141 on risperidone, and 41 on trifluperazine. Primary outcome measurement for relative effectiveness is the time to the discontinuation of study medications, with reasons for discontinuation as secondary outcome measurement.

Results: Ninety percent of patients discontinued their medications before 18 months. Haloperidol (96%), risperidone (86%), and olanzapine (93%). The majority who discontinued was due to intolerability of medications’ side effects (41%). Of these who discontinued, 48% of patients on first-generation antipsychotics vs. 35% of patients on second-generation antipsychotics discontinued due to intolerability of side effects (p=0.004). Olanzapine (25%) had the lowest frequency of discontinuation due to intolerability of side effects vs. haloperidol (51%, p<0.001) and trifluperazine (42%, p=0.002).

Conclusion: A large majority of patients discontinued from their medications, of which, majority was due to intolerability of medications’ side effects. Risperidone appeared to be more effective than haloperidol in having a longer time to discontinuation, whilst olanzapine had the lowest frequency of discontinuation due to intolerability of side effects compared to haloperidol and trifluperazine.

AIM/OBJECTIVES
Paraphrenia is a psychotic disorder characterized for a better-preserved affect and rapport than paranoid schizophrenia and for systematized delusions that are not encapsulated from the rest of the personality as in delusional disorder. Actually it is not recognized among current classifications of mental disorders. However, clinicians usually recognize this entity in their daily practice. Few researches on paraphrenia have been conducted in the past years. The aim of this paper is to describe the clinical and related variables from patients admitted to a psychiatric ward who were diagnosed of paraphrenia and discuss the validity of this clinical entity in the psychiatric nosology.

METHOD
We studied the clinical histories of all patients admitted to our hospital in the period 1998 - 2006 who received the diagnosis of paraphrenia (ICD-9 criteria) at discharge.

RESULTS
Sample was composed by 9 cases (5 men, 4 women) with age between 26 and 75 years (illness onset; mean age of 31 years). All patients presented multiple delusions. Harm delusions were the more frequently (88.9%) reported in our sample. Hallucinations were presented in 4 cases (auditory hallucinations in 3 cases). 44% of patients had familiar history of psychosis. According with Kraepelinnian nosology most of cases were classified as fantastic (44%) or expansive (33%) paraphrenia.

CONCLUSIONS
Paraphrenia is still a useful diagnosis to clinicians for a certain group of patients, not classifiable as paranoid schizophrenia nor delusional disorder.

QUETIAPINE IN FIRST-EPISODE SCHIZOPHRENIA: A PHARMACOECONOMIC ANALYSIS

INSTITUTIONS
1. The Moscow Research Institute of Psychiatry, Outpatient Psychiatry, Moscow; Russian Federation

AUTHORS
1. Isaak Ya Gurovich, Dr, MD, PhD, lyubova@post.ru
2. Evgeny B Lyubov, Dr, MD,PhD, lyubova@post.ru

Aims: to evaluate the cost effectiveness of Quetiapine (Q) in maintenance treatment of first-episode schizophrenia (ICD-10) vs Haloperidol (H) treatment.

Methods: A Markov simulation model has been developed for 1-year treatment period with incorporated data from meta-analyses and original pharmacoepidemiologic study.

Results: The cost of Q treatment exceeds those of H more than 10 times (4,000 and 40,000 Roub 2004 / patient/ year, respectively). However Q demonstrated substantial economical advantages vs H from societal perspective caused by significantly increasing time of remission (22.4 vs. 66.6 days/year for Q- and H-treated subjects, respectively). The cost of additional remission day was 1021 Roub. The results were not robust in a sensitivity analysis, including variations in the cost of hospitalization, and/or the acquisition cost of Q, and the value of the regional Domestic Product.

Conclusion: Choice of Q may be a cost saving strategy for subpopulation of patients in early stages of schizophrenia. Disproportionally higher the wholesale cost of Q compared to the cost of mental health care in Russia essentially influenced on results. Clinical and economic flexible criteria should be developed as a guideline for appropriate prescribing in «real world» practice and evidence based treatment with Q in first-episode schizophrenia.

GROUP PSYCHOTHERAPY FOR CHRONIC PSYCHIATRIC PATIENTS, RELATING PANSS & CGI SCALE

INSTITUTIONS
1. Center for Mental Health, Kotor, Serbia and Montenegro
2. Special Psychiatric Hospital Dobrota, Kotor, Serbia and Montenegro

AUTHORS
1. Aleksandar Macic1, Dr, filstem@cg.yu
2. Milka Novovic2, Dr, filstem@cg.yu
3. Andrija Cetkovic1, Dr, czmkotor@cg.yu

In October 2007, team from Mental health center Kotor initiated group therapy for patients suffering from chronic schizophrenia, with the aim to improve their social skills and help them include in the community easier. The therapy is based on the principles and methods of Supportive and Cognitive-behaviour psychotherapy. The sessions are held twice a week and last two hours. The goal is to find out whether group therapy has any influence on the score in any item of PANSS scale, as well as to determine if and how much its effects is different with patient treated with “specific” antipsychotics, compared to group treated with “non-specific” antipsychotic. The test includes four groups of patient, two groups of 12 members and two of 20 members, both sexes, age between 35-45, all with a diagnosis of chronic paranoid schizophrenia. The first 12-member is in group psychotherapy and are being given specific AP, the second 12-member group is also in group psychotherapy, but are being given non-specific AP, the first 25-member group are being treated with only specific AP, the second 25-member group with only non-specific AP. All patients had been evaluated on PANSS and CGI scale before the beginning of the research, the evaluation being repeated every month. We are planning to carry out this research until September, 2008, when the results will be processed.

METABOLIC SAFETY ANALYSIS OF OLanzAPINE (LONG-ACTING INJECTION VS ORAL)

INSTITUTIONS
1. Eli Lilly and Company, Lilly Research Laboratories, Indianapolis, United States

AUTHORS
1. David P. Mcdonnell1, Dr., M.D., zyp_sci_comm@lilly.com
2. Ludmila A Kryzanovskaya1, Dr., M.D.
3. Fangyi Zhao1, Dr., Phd
4. Holland C Detke1, Dr., Phd
5. Peter D Feldman1, Dr., Phd

Objectives: To characterize potential metabolic changes during treatment of schizophrenia in patients receiving olanzapine long-acting injection (OLAI) versus oral olanzapine in a large, double-blind, randomized study.

Methods: Male and female adult patients (ages 18-70) with schizophrenia were stabilized on oral olanzapine (10, 15, or 20 mg/d) for at least 4 weeks and then randomly assigned to either continued oral olanzapine treatment (n=322) or OLAI (n=599; 150 mg/2 weeks, 405 mg/4 weeks, or 300 mg/2 weeks) for up to 24 weeks. Assessments included comparisons of mean and categorical changes from baseline (time of randomization) in metabolic measures (weight, body mass index [BMI], fasting glucose, and fasting lipids).

Results: Mean changes in weight, glucose, and most lipids were not significantly different between treatment groups. Weight changes over time followed similar patterns and were not significantly different at endpoint between treatment groups. Incidence rates of weight gain ≥7% or ≥15%, or of weight gain as an adverse event, were not significantly different between treatment groups. However, among patients considered obese (BMI ≥30) at baseline, only those receiving oral olanzapine showed significantly increased mean weight. In contrast, LDL cholesterol decreased significantly less among OLAI-treated patients. Nevertheless, incidence rates of potentially clinically significant changes in glucose and lipids were similar between treatment groups, regardless of baseline status, and rates of diabetes- or dyslipidemia-related adverse events, which were low in both groups, were not significantly different between treatment groups.

Conclusions: In general, metabolic changes during OLAI treatment appear similar to those during oral treatment.

6. Daniel Lin1, Dr., PhD

Objective: To examine the efficacy and safety of olanzapine long-acting injection (OLAI) for maintenance treatment of patients with schizophrenia.

Method: Adult outpatients who maintained stability on open-label oral olanzapine (10, 15, or 20mg/day) for 4-8 weeks were randomized to OLAI 150mg/2wks (N=140), 405mg/4wks (N=318), or 300mg/2wks (N=141), or to oral olanzapine at their previously stabilized dose (N=322) for 24 weeks of double-blind treatment. The primary efficacy measures were cumulative rates of and time to relapse.

Results: At 24 weeks, 93% of oral olanzapine-treated patients, 95% of 300mg/2wks-, 90% of 405mg/4wks-, 84% of 150mg/2wks-, and 69% of 45mg/4wks OLAI-treated patients remained relapse-free. The 405mg/4wks and pooled 2-week dosing regimens were noninferior to oral olanzapine as well as to each other. All 3 higher OLAI doses were superior to 45mg/4wks based on time to relapse (all p<.01). Incidence of weight gain ≥7% of baseline was significantly greater for oral olanzapine (21.4%), OLAI 300mg/2wks (20.7%), 405mg/4wks (15.2%) and 150mg/2wks (16.4%), compared with OLAI 45mg/4wks (8.3%, all p<.05). There were no clinically significant differences between OLAI doses and oral olanzapine with respect to injection site reactions, laboratory measures, vital signs, ECGs, or EPS. Two patients treated with OLAI experienced sedation and delirium following accidental intravascular injection.

Conclusions: OLAI at doses of 150mg/2wks, 405mg/4wks, and 300mg/2wks was efficacious in maintenance treatment of schizophrenia for up to 24 weeks. The safety profile for these OLAI doses was consistent with that of oral olanzapine except for injection-related events.

4. Scott Andersen1, Mr., MS
5. Daniel Lin1, Dr., PhD
6. Holland Detke1, Dr., PhD

Objective: To examine the efficacy and tolerability of olanzapine long-acting injection (OLAI) for the treatment of acutely ill patients with schizophrenia.

Method: In this 8-week, double-blind study, 404 acutely ill adult patients were randomized to receive 210mg/2wks, 300mg/2wks, 405mg/4wks OLAI, or placebo/2wks. No oral antipsychotic supplementation was permitted. The primary efficacy measure was mean baseline-to-endpoint change in Positive and Negative Syndrome Scale (PANSS) Total score.

Results: Mean baseline-to-endpoint decreases in PANSS Total scores were significantly greater for all OLAI regimens relative to placebo (-22 to -26 vs. -9 points; all p<0.001). The 300mg/2wks and 405mg/4wks OLAI groups separated from placebo on the PANSS Total at 3 days after starting treatment, and all OLAI groups separated from placebo by 7 days. Incidences of sedation and increased appetite were significantly higher for 300mg/2wks OLAI relative to placebo (p<0.05). Mean weight gain (3.2-4.8 vs. 0.3kg, p<0.001) and incidence of weight gain ≥7% of baseline (23.6-35.4% vs. 12.4%, p=0.002) were significantly greater for OLAI relative to placebo. Significant differences between OLAI and placebo were observed with mean changes in fasting total cholesterol (5.5-10.4 vs. -7.0mg/dL; p=0.015), and fasting triglycerides (17.6-30.3 vs. -9.4mg/dL; p=0.016). Injection site reactions occurred in 3.6% of OLAI patients vs. 0% for placebo (p=.073).

Conclusions: OLAI administered at 2- or 4-week intervals was significantly more efficacious than placebo for the treatment of acutely ill patients with schizophrenia without oral antipsychotic supplementation. Efficacy and safety findings were consistent with those seen in similar studies conducted using oral olanzapine.

OLANZAPINE LONG-ACTING INJECTION
PHARMACOKINETICS AND DOSING DATA

INSTITUTIONS
1. Eli Lilly and Company, Lilly Research Laboratories, Indianapolis, United States

AUTHORS
1. Holland Detke1, Dr., PhD
2. David McDonnell1, Dr., MD, zyp_sci_comm@lilly.com
3. Richard Bergstrom3, Dr., PhD
4. Daniel Lin1, Dr., PhD
5. Angela Gulliver1, Dr., PharmD

Objective: Pharmacokinetic and efficacy data for olanzapine long-acting injection (OLAI) were assessed to determine dose correspondence relative to oral olanzapine.

Methods: Patients with schizophrenia (N=1065) on a stabilized dose of oral olanzapine for at least 4 weeks were randomized to double-blind treatment with OLAI or to continued treatment on their same dose of oral olanzapine for up to 24 weeks. Oral antipsychotic supplementation was not allowed. Cox proportional hazard models were used to calculate relative risk of relapse.

Results: OLAI doses of 150mg/2wks, 405mg/4wks, and 300mg/2wks produced 10th-90th percentile steady-state plasma concentrations (5-41, 8-51, 7-73ng/ml) similar to those for 10, 15, and 20mg/day oral olanzapine (13-48, 21-63, 21-85ng/ml). Steady-state concentrations were achieved after approximately 3 months of treatment. The relative risk of relapse over 24 weeks indicated a correspondence between OLAI and oral dosing regimens. Patients stabilized on 10mg/day oral who were randomized to 405mg/4wks OLAI showed approximately equal risk as those who remained on a 10mg/day oral dose (hazard ratio [HR]=1.03). Patients stabilized on 15 or 20mg/day oral who were randomized to 300mg/2wks OLAI showed lower or approximately equal risk relative to staying on oral (HR=0.68 and HR=1.13, respectively).

Conclusions: Pharmacokinetic and efficacy data suggest a correspondence between available oral doses and proposed OLAI doses. Data also indicate that patients can be switched directly from oral olanzapine to OLAI without oral supplementation and with a low risk of relapse if switched to an appropriate corresponding dose.

5. Antonio Vita3
6. Antonio Sciarretta4
7. Claudio Mencacci5
8. Paola Tiradritti6

Aims: A cohort of Italian patients was assessed to confirm decreases in weight and improvements in metabolic parameters resulting from a switch to ziprasidone from other antipsychotics.

Methods: In 2 similar 8-week studies, patients with schizophrenia not tolerating or responding to olanzapine, risperidone, quetiapine, or haloperidol were switched to open-label ziprasidone, 80-160 mg/d. Data from the 2 studies were pooled and mean change from baseline at Week 8 in weight and metabolic parameters were analyzed. Primary efficacy variables were changes from baseline in PANSS total and CGI-S at Weeks 1-8; a paired t test assessed statistical significance of change from baseline at each follow up visit (LOCF).

Results: 510 patients were randomized, 501 received ziprasidone. In the pooled analysis, weight decreases (kg) at Week 8 were -1.70 (p<0.0001), -1.43 (p<0.0001), -0.78 (p=0.046), and -0.44 (p=0.073) after switching from olanzapine, risperidone, quetiapine, and haloperidol, respectively. Corresponding changes in metabolic parameters were: body mass index (kg/m2), -0.61 (p<0.0001), -0.49 (p<0.0001), -0.27 (p=0.034), and -0.13 (p=0.129); total cholesterol (mg/dL), -16.13 (p<0.0001), -9.83 (p=0.005), -9.27 (p=0.096), and -4.65 (p=0.083); and glycosylated hemoglobin (%), -0.20 (p=0.004), -0.11 (p=0.049), and 0.03 (p=0.756). PANSS total and CGI-S scores improved significantly from baseline.

Conclusions: These data confirm that switching from other antipsychotics to ziprasidone leads to improvements in weight and metabolic parameters.

Introduction: It is well established that SZ is associated with difficulties in recognizing facial emotional expressions, but few studies have reported the presence of this deficit among their unaffected relatives. This study attempts to add new evidences of familial association on a test of emotion expression processing.

Methods: This study evaluated the performance of 94 paranoid SZ patients, 150 first-degree relatives of probands from multiplex SZ families, and 115 nonpsychiatric controls on a facial emotional recognition test using a computer morphing technique to present the dynamic expressions. The task entailed the recognition of a set of facial expressions depicting the six basic emotions presented in 20 successive frames of increasing intensity.

Results: The findings indicated that SZ patients were consistently impaired for the recognition of the six basic facial expressions. In contrast, their unaffected relatives showed a selective impairment for the recognition of disgust and fearful expressions.

Conclusions: Familial association of selective facial emotional expressions processing deficit may further implicate promising new endophenotypes that can advance the understanding of affective deficits in SZ.

CHARACTERISTICS OF ANTIPSYCHOTIC PRESCRIPTIONS PRIOR TO THE INTRODUCTION OF CLOzapine

INSTITUTIONS
1. UNIVERSITY OF SÃO PAULO - SCHOOL OF MEDICINE, DEPARTMENT & INSTITUTE OF PSYCHIATRY, São Paulo, Brazil

AUTHORS
1. Anny Karinna P. M. Menezes1, Dr., akmenezes@hcnet.usp.br
2. Helio Elkins1, Dr., PhD, helkis@usp.br
3. Belquiz S. Avrichir1, Dr., MD, Bavrichir@usp.br

Introduction: In the last few years, evidence-based guidelines and international algorithms(1) have established that clozapine is the drug of choice to treat refractory schizophrenia and should be introduced after failure of two trials of six weeks each with different antipsychotics. However, certain authors have found a delay up to 5 years for the introduction of clozapine in countries such as the United Kingdom(2).

Objectives: To measure the delay period for the introduction of clozapine and to identify the characteristics of the treatment used prior to clozapine’s introduction in the Institute of Psychiatry in São Paulo, Brazil.

Method: By using chart review we analyzed the treatment variables prior to the introduction of clozapine : (a)number of antipsychotic treatments (b)classes of antipsychotics used (c)adequacy of treatments regarding dose and length (d)number of treatments using only one antipsychotic drug (e)antipsychotic polytherapy and (f)total time elapsed until clozapine introduction. The Student's t test and the Logistic Regression were used for data analysis.

Results: We verified a theoretical delay in the clozapine introduction in 69.4% of the evaluated cases, especially amongst men. The use of this medication was delayed due non evidence based procedures such as the use of antipsychotics for longer periods than necessary, the combination of more than one antipsychotic (polytherapy) and prescription of the same antipsychotic at different moments. The delay was of almost one year(334 days).

UNTREATED PARANOID SCH AS DETERIORATION FACTOR OF HARD FELONIES TO POPULATION OF FORENSIC PATIENTS

INSTITUTIONS
1. Special psychiatric hospital Dobrota, Kotor, Serbia and Montenegro

AUTHORS
1. Tanja D Mijatovic-Papic, Dr.
2. Nevenka S Duletic, Dr.
3. Aleksandar B Tomcuk, Dr.
4. Branislava N Cizmovic, Dr.

Between psychiatric patients which are performing hard felonies, with the following diagnostics categories and felony characters during last 12 months in forensic ward of the Special psychiatric hospital, is became evident that 5 of 21 hospitalized patients are committed murder and all of them /TEMPORAR CRIMINIS/ were in mentally incompetent condition because of mental sickness with permanent character - in other words, paranoid SCH psychosis. In 4 of 5 mentioned cases, sickness is first time diagnosed during a forensic psychiatric examinations leaded toward lawbreakers during an investigation; based on estimations of examinees’ clinical status and their familiar and social dysfunctionality it is concluded that the beginning of sickness dated long time before execution of subject felony but patients weren’t been on psychiatric view and they have never been psychopharmacological treated. During the hospitalization these patients are ordinarily psychopharmacologic treated which is brought to reduction of psychotic psychopathology and according to indicators - aggressively scale till significant degradation risk of auto and heterodestructive behavior. It’s pointing on conclusion that absence of adequate medicamentsy treatment is brought to basic sickness progression and psychotic alienation from reality which cause destructive and homicidal act. Considering the biggest amount of chronic patients which are ailing of paranoid schizophrenia and which are ordinarily psychiatric treated, and in own life history they have never done any hard felony, although is talk about psychiatric sickness with permanent character; mentally disturbed persons cannot be considered as permanently tamable for environment or themselves.

Key words: untreated paranoid SCH, tenability

FRACTALS IN PSYCHIATRY: THE DISTURBANCE OF A “GOLD SECTION” BETWEEN OPPOSITE PAIRS OF EGO-DEFENSE MECHANISMS IN SCHIZOPHRENIA

INSTITUTIONS
1. Kyrgyz - Russian (Slavonic) University, Psychiatry and Clinical Psychology, Bishkek, Kyrgyzstan
2. Tulane School of Medicine, Department of Psychiatry, New Orleans, United States

AUTHORS
1. Elena S. Molchanova, Dr., MD, PhD, molchanova_e@mail.auca.kg
2. Patric Marius Koga, Dr., MD, PhD, pmkoga@ucdavis.edu

Aims/Objectives
Unlike the “normal” functioning of opened dissipative structures (like psychic functions are) governed by the laws of nonlinear chaos, psychopathological changes may occur in much more ranked and well-ordered patterns. To test this hypothesis, this study has applied Mandelbrot’s [1] fractal geometry to a quantitative analysis of Ego-defense mechanisms in schizophrenia.

Method
Kellerman’s psychoevolutionary theory of emotions, ego-defense mechanisms and cognitive styles became the basic paradigm of this research. Life Style Index of Conte & Plutchik, and the Semantic Differential (SD) were used to measure the quantitative indices of Ego-defense mechanisms in patients with schizophrenia, somatoform disorders and healthy respondents.

Results
Comparative analysis of the intensity of Ego-defense mechanisms (EDM) in three groups of patients (60 patients with schizophrena-nia, 100 healthy respondents and 80 patients with somatoform disorders) confirmed that EDM tension is much higher (p<0.001) in schizophrenia in comparison with healthy and neurotic respondents. The analysis of graphical EDM portraits confirmed the more symmetrical and well-ordered structure of EDM graphics in schizophrenia in comparison with healthy respondents and patients with somatoform disorders. Further computations revealed that while the quantitative indices of paired EDM in healthy respondents are in a ratio similar to the famous 1, 618 “golden section rule”, the ratio is disturbed in schizophrenia.

Conclusion
The fractal analysis of EDM graphic portraits seems to enhance the predictive power of psychiatric prognosis for the further directions of development of schizophrenia.

THE 15-YEAR OUTCOME OF IRAQI PATIENTS WITH SCHIZOPHRENIA IN BABYLON, IRAQ

INSTITUTIONS
1. Faculty of medicine and health sciences, UAE University, psychiatry, Al Ain, United Arab Emirates

AUTHORS
1. Ali Abdurahaman Younis¹, Dr. FRCPsych, arionnis@hotmail.com
2. Hamdy Fouad Moselhy¹, Dr. MD, MRCPsych, hamdy.fouad@uaeu.ac.ae

Objectives: to explore the differential outcome of schizophrenia in Iraq. In a 15-year follow up study, 298 patients with first-onset schizophrenia in 1986-1987 were recruited from all subjects who had been consecutively visited the psychiatric service in Merjan Hospital in Al-Hilla city, Iraq. Of these, 84 were excluded, 214 were included in the study. The pattern of outcome were assessed by a pre-designed questionnaire based on ICD-10

Results: A 150 males and 64 females with average age of onset as 24.8 years. Forty three subjects were untraceable, and 12 subjects committed suicide, 11 subjects with alcohol dependence, 8 subjects with clear learning disability, 7 subjects with organic brain diseases, and 3 subjects with epilepsy. All of them were excluded in the analysis. More than 47% of subjects at final assessment had good or partial symptomatic and psychosocial outcome and nearly 53% had poor outcome. A hundred and twenty eight of the subjects suffered positive symptoms (87 males and 41 females) and 86 suffered negative symptoms (63 males and 23 females). Thirty patients (20%) of the male group showed good prognosis versus 31.3% of the female group. Furthermore, 54.7% of the male group were in bad prognosis group versus 48.7% of the female group.

Clinical implications: despite Iraq exposed to economic sanctions, its schizophrenia outcome was similar to that in developing countries. The existence of supportive family, strong religious beliefs, and strict committed regimen for active follow-up treatment may be important contributory factors to better outcome.

Aims: Mobile elements can move around the human genome. They perturb construction and expression of neighboring genes, thus leading to a genomic instability and causing various diseases. Their behaviors are usually suppressed by methylation systems, but these systems can be very unstable in a stage of neuronal development or under stressful conditions. As to schizophrenia, genomic instability and aberrant methylation are being observed. Thus, we speculated that in low or aberrant methylation, the behavior of mobile elements might be affecting the gene responsible for schizophrenia. Based upon this hypothesis, we investigated the novel insertion sites of mobile elements in a patient with schizophrenia to identify risk genes. Screening assay was carried out on one of the well-known human mobile elements, retroposon Alu.

Methods: We screened for the patient-specific Alu insertion in genomic DNA from one pair of case-parent trios for schizophrenia using Alu-specific PCR with microarray.

Results: We have identified patient-specific mutations in three spermatogenesis-related genes.

Conclusions: The patient-specific mutated genes which might be the risk genes for schizophrenia were selected in this study. Spermatogenesis-related genes are known to contribute to the diverse cellular processes in somatic cells, such as apoptosis, differentiation, and transcriptional regulation. Our results may provide an explanation for various biological characteristics and risk factors for schizophrenia.

This study was done under the approval of the Ethical Committee for Genetic Research, Teikyo University School of Medicine.

ASSOCIATIONS BETWEEN PSYCHOTIC-LIKE EXPERIENCES AND SUICIDAL IDEATION AND SELF-HARM BEHAVIORS AMONG JAPANESE EARLY TEENS

INSTITUTIONS
1. Mie University, Graduate School of Medicine, Psychiatry, Tsu-city, Japan
2. Fujita Health University, Public Health, Toyoyake, Aichi, Japan
3. University of Tokyo, Health Service Center, Bunkyoku, Tokyo, Japan
4. Tokyo Metropolitan Matsuzawa Hospital, Psychiatry, Setagaya, Tokyo, Japan

AUTHORS
1. Atsushi Nishida, Mr., PhD, 304d033@m.mie-u.ac.jp, 2. Hisashi Tanii, Dr., MD, PhD, 3. Yukika Nishimura, Mrs., PhD, 4. Naomi Kajiki, Mrs., MS., 5. Ken Inoue, Mr., MD, PhD, 6. Tsukasa Sasaki, Mr., MD, PhD, 7. Yuji Okazaki, Mr, MD

Objective: It is widely known that the risk of suicide is higher in cases of psychotic disorders in comparison to the general population. Recent epidemiological studies have reported that psychotic disorders are continuous with common psychotic-like experiences in general population. This study is aimed to examine the associations between psychotic-like experiences (PLEs) and suicidal ideation and self-harming behaviors in a general population of adolescents.

Method: PLEs were studied using a self-rating questionnaire in 5073 Japanese junior-high school students aged 12-15 years. Suicidal ideation and self-harming behaviors were also studied using a self-rating questionnaire. Symptoms of depression and anxiety were evaluated using the 12-item General Health Questionnaire (GHQ-12). This study was approved by the ethics committee of Mie University School of Medicine.

Results: Psychotic-like experiences were strongly and independently associated with both suicidal ideation (OR = 2.4, 95% CI 1.6 - 3.5) and self-harming behaviors (OR = 3.7, 95% CI 2.4 - 5.7) after controlling the effects of age, gender and GHQ-12 scores. In addition, the severity of PLEs was significantly related to both suicidal ideation and self-harming behaviors (Cochran-Armitage trend test; p < 0.001).

Conclusion: Psychotic-like experiences in a general population of early teens seem to be related with the factors which may associate with suicidal behaviors. This should be taken into account for suicide prevention researches.

JAPANESE VERSION OF BONN SCALE FOR THE ASSESSMENT OF BASIC SYMPTOMS, ITS RELIABILITY AND ITS VALIDITY

INSTITUTIONS
1. Tokyo Medical and Dental University, Tokyo, Japan
2. Tokyo University of Social Welfare, Japan
3. Tokyo Kougyou University, Japan
4. Inagidai Hospital, Japan
5. Kanuma Hospital, Japan

AUTHORS
1. Kazunari Oshima, Dr, MD, oshima.pysc@tmd.ac.jp, 2. Tsukasa Okimura, Dr, MD, 3. Tomoaki Yukizane, Dr, MD, 4. Katsuhiko Yasumi, Dr, MD, 5. Jun Iwawaki, Dr, PhD, 6. Toru Nishikawa, Prof, PhD, 7. Seiichi Hanamura, Prof, PhD

Background: Basic symptoms are self perceivable neuropsychological deficits which continue for decade. Huber and Gross completed it and Klosterkotter regroups 5 clusters with cluster analysis.

Objectives: The aim of this research is to show reliability and validity of BSABS Japanese Version which has 5 clusters which include 52 items: Cluster1: thought, kanguage, perception and motor disturbance, Cluster2: Impaired bodily sensations, Cluster3: Impaired stress to normal stress, Cluster4: Disorders of emotion, affect and memory, Cluster5: Emocional reactivity, disability to maintain so-cial contacts.

Methods: We evaluated with BSABS 105 inpatient in University Hospital. 65 patients have the diagnosis of schizophrenia with DSM-IV and 40 are not schizophrenic but have some psychotic symptoms with a definition of DSM-IV and have decreased social function. We examined, first, interraters reliability, secondly, correlations of 5 clusters by using Spearman’s correlation confident. Finally, diagnostic validity(specificity and sensibility) of 5 clusters with ROC curves.

Results: Interrater reliability is high as follows: In 49 items of 52, Cohen Kappa statistics is higher than 0.7. With Spearmann’s rank, correlation of each clusters are high, in addition, Cronbach à statistics are 0.788. Statistical description of the ROC curves are as follows: Areas under ROC curve of cluster1 is 0.714, that of cluster2 is 0.561, that of cluster3 is 0.711, that of cluster4 is 0.739, that of cluster5 is 0.638

Conclusion: Japanese Version of BSABS has a sufficient reliability and validity for evaluating symptoms of schizophrenia. The results of ROC curves suggest that cluster3 has the highest diagnostic vali-dity to differentiate schizophrenia from other mental disorders with psychotic symptoms.

We studied the initial health condition of 50 schizophrenic patients (DSM-IV TR diagnostic criteria) treated with antipsychotics and the variation after a 90 days follow up. We analyzed the biological constants, weight, CMI, blood tests (glucose, urea, uric acid, creatinine, cholesterol, triglycerides, total lipid levels, bilirubin, ALT, AST, GGt, sodium, potassium, chlorine, CPk, amylase and thyroid function), basic urine, thoracic X-Ray and EKG. We evaluated the side effects of the antipsychotics using the UKU scale and CGI. Subtype of illness, adherence to treatment and clinical evolution are correlated with the physical health and the side effects.

The results are discussed.

**Purpose:** Knowing patients’ opinions about their feelings about disease and the influence of schizophrenia on their life.

**Materials and methods:** The article presents the results of studies on hospital patients suffering from paranoid schizophrenia (during the examination the patients did not demonstrate the psychotic symptoms). Authors wanted to know the patients’ opinions about the changes made by mental disease in their life (family life, daily life, school, work). Fifty patients had to answer 23 questions, in a part of them answers were YES or NO, but in the main patients had to write a few sentences about their impressions of their life situation and problems concerning emotions (happiness, fear, trust, love, friendship, loneliness), religion (faith, sins, suicide thoughts) and treatment.

**Results and conclusions:** Less than half of the patients recognized themselves as ill people, but were not able to show the moment in their life, which could have caused the disease. At the same time half of patients’ relations with their families got worse, but they were looking optimistically in the future.

2. Eung-Jo Kim¹, Dr., MD
3. Joo-Eon Park¹, Dr., MD
4. Kye Hyun Hong², Dr., MD

Objective: To evaluate the quality of life (QOL) of patients with schizophrenia (SPR) and to compare QOL among atypical antipsychotics medication group and conventional antipsychotics medication group, we report a retrospective analysis of consecutive 41 patients with SPR who were treated between 2005 and 2008.

Methods: Patients with ICD-10 F20 schizophrenia were included. 41 patients with SPR took inventory of epidemiological questions. A questionnaire concerning recent symptoms and the Short Form 36(SF-36) QOL instrument were presented to patients and were assessed. Also medication lists of patients were examined.

Results: Mean scores of health status were higher in high income and atypical antipsychotics medication group. The relationship between familial support and social functioning, mental health, general health were revealed significantly.

Conclusions: Therefore we reviewed evidence that kinds of antipsychotics and socio-economic condition are associated with health status in this study, and that the strength of the familial support was a important to maintain health.

OUTCOME OF THE SERTINDOLE COHORT PROSPECTIVE (SCOP) STUDY: ALL-CAUSE MORTALITY

INSTITUTIONS
1. UPC KU Leuven, University Centrum St Jozef, Kortenberg, Belgium

AUTHORS
1. Joseph Peuskens¹, joseph.peuskens@uc-kortenberg.be
2. SCOP study group²

Background: Many schizophrenia patients do not respond to the available drug therapy, and among those who do, significant adverse reactions often compromise therapeutic success. Sertindole is an efficacious atypical antipsychotic with good tolerability and is currently launched in approx 30 countries. A known dose-dependent QT prolongation gave rise to a cardiac safety concern, therefore a post-marketing surveillance study, SCOP (Sertindole Cohort Prospective), was initiated.

Aim: To compare the safety of sertindole in the treatment of schizophrenia with that of the widely used antipsychotic risperidone.

Methods: This was a prospective, randomised, partially blinded, active-controlled, multinational trial. The study was conducted under normal conditions of use (i.e. inclusion criteria were deliberately broad) to ensure high external validity. The primary endpoint, all-cause mortality, is a measure highly resistant to bias. An Independent Safety Committee has been classifying the events, using blinded data, and providing advice to the Independent Management Committee overseeing the trial.

Results & Discussion: The SCOP study is one of the largest post-marketing surveillance studies ever conducted in schizophrenia research. Initiated in 2002, it was decided to end the study in September 2007. The decision to end the study was based on data, indicating that its continuation was unlikely to provide significant additional primary endpoint information. At this stage the study had enrolled 587 investigators, around 9,885 patients and accrued approximately 15,000 PYE over 5 years at 594 sites in 38 countries. Primary endpoint results, all-cause mortality, will be presented.

Background: The misreporting of height and weight and, consequently, of the body mass index (BMI), has been associated with age, sex and medical disease status in the general population. The correlates of BMI misreporting in psychiatric disorders has not been investigated yet. We examined the prevalence of BMI misreporting in patients with schizophrenia and the factors associated with it.

Methods: We recruited 111 patients with schizophrenia who were hospitalized in two acute psychiatric wards or were accommodated in several residential structures (hostels, apartments, boarding houses) of the Psychiatric Hospital of Attica. Objective and self-reported (sBMI) BMI indices were calculated after the patients reported their height and weight. Patients were divided into three groups according to the accuracy of BMI reporting (over-, under- and correct reporters). Demographic, metabolic and clinical characteristics of the patients were also recorded.

Results: In 22.5% of patients sBMI>BMI, in 44.1% sBMI<BMI, while in 4.5% sBMI=BMI. The mean age of each group was 49.36 (SD=13.51), 53.9 (SD=13.56) and 34.6 (SD=14.1) years, respectively. Under-reporters were older compared with over- and correct-reporters (p=0.01). The three groups did not differ in terms of their gender, other demographic, metabolic or clinical characteristics.

Conclusions: The patients with schizophrenia of our sample under-reported their BMI. A regular BMI assessment, based on objective measurement rather than subjective reporting is needed for schizophrenia patients.

AIMS: To investigate the attitudes of patients with Schizophrenia and mental health professionals (MHP) to smoking and smoking cessation.

METHODS: A questionnaire was distributed to 207 MHP (77 psychiatrists and psychiatric residents, 99 nurses, 31 psychologists) working in the Psychiatric Hospital of Attica. A second questionnaire was given to 116 patients suffering from DSM-IV schizophrenia, hospitalized in an acute ward or living in psychiatric residential structures.

RESULTS: 74.1% of patients were smokers with 33.7% of them smoking more than 2 packets/day. 58.1% of patients have tried to quit in the past, while 48.8% would like to quit now and 36% to participate in a smoking cessation program. 68.6% of MHP (75.3% of psychiatrists, 63.4% of all smokers), believe that a smoking cessation program would be useful for patients with schizophrenia, with most favoring both pharmacological and psychotherapeutic methods. However, 44% of participants believe that smoking has a therapeutic role in these patients and 46.9% offer them cigarettes (68.7% of nurses, 32.5% of psychiatrists). Finally, 84.1% of MHP and 43.3% of patients (35.9% of smokers) agree with the perspective of a partial smoking ban in psychiatric units, with the creation of a special 'smoking room' in each unit, although 71.5% of all professionals believe that the clinical picture of these patients will become worse in case of a total smoking ban.

CONCLUSIONS: Half of the schizophrenic patients of our sample are willing to quit smoking, while most MHP support a smoking cessation program and a partial smoking ban in psychiatric units.

DIABETES AND INSULIN-RESISTANCE IN A SAMPLE OF CHRONIC SCHIZOPHRENIC INPATIENTS

INSTITUTIONS
1. Complejo Hospitalario Universitario, Psychiatry, Santiago de Compostela, Spain

AUTHORS
1. Ramón Ramos-Ríos, treseres30@yahoo.es, 2. Manuel Arrojo-Romero, 3. Eduardo Paz-Silva

Objectives
Recently the interest for the medical comorbidity of patients with schizophrenia has increased. The metabolic syndrome has been the focus of several investigations because of its association with elevated rates of mortality and conditions such as type 2 diabetes mellitus and cardiovascular disease. Increased abdominal adiposity and, strongly associated with it, insulin resistance, play a key role in the development of the complete metabolic syndrome. The aim of this study is to determine the prevalence of disturbances in glucose metabolism and its related factors, in patients with chronic schizophrenia.

Methods
Different metabolic and anthropometric parameters (fasting glucose, fasting insulin, triglyceride levels, HDL-cholesterol, BMI, waist circumference, blood pressure) were studied in chronic schizophrenics from a psychiatric hospital (Hospital Psiquiátrico de Conxo, Santiago de Compostela, Spain). Insulin-resistance was evaluated by the HOMA method.

Results
We studied 182 schizophrenics (65.9% men) with a mean age of 55.14 years (SD 15.25). Only 19.8% were treated with antipsychotic monotherapy. 14.8% had the diagnosis of diabetes, 44.8% presented hyperglycemia (fasting glucose > 100mg/dL) and 6.6% hyperinsulinaemia. A significant association (p< 0.01) was found between insulin-resistance and BMI, waist circumference, triglyceride levels and diastolic blood pressure. High insulin-resistance was also significantly associated with low levels of HDL-cholesterol. No relation was found between insulin-resistance and age, years of evolution or type of antipsychotic treatment.

Conclusion
Insulin-resistance appears to be associated with the severity of the parameters that define the metabolic syndrome. Future studies are needed to identify and understand the mechanisms by which medication or the course of the disease can cause insulin-resistance.

Background: A series of inflammatory and immune alterations has been described in schizophrenia. Chemokines are a subgroup of cytokines that play a major role in the recruitment of determined subsets of leukocytes into tissues. To date no study has evaluated whether levels of chemokines are altered in patients with schizophrenia.

Objective: To evaluate serum levels of CC and CXC chemokines of schizophrenic patients and age- and gender-matched controls.

Methods: Forty male institutionalized schizophrenic patients (mean ± SD age, 52.3 ± 9.9) and 20 asymptomatic matched controls were recruited for this study. Severity of symptoms was assessed using BPRS, PANSS and AIMS. All patients were under typical antipsychotic treatment. Serum levels of chemokines were measured by ELISA.

Results: There was no statistical difference in serum levels of CCL2, CCL3, CCL24, CXCL9 and CXCL10 between controls and patients. Serum levels of CCL11 were increased in schizophrenic patients when compared with controls. Serum levels of chemokines were not correlated with the length of disease or hospitalization and the severity of involuntary movements, positive and/or negative symptoms.

Conclusion: CCL11 is a ligand forCCR3, a receptor expressed preferentially on Th2 lymphocytes, mast cells and eosinophils. Higher serum levels of CCL11 in schizophrenia reinforce the view that this disease may be associated with a Th1/Th2 imbalance with a shift towards a Th2 immune response.

5. António Marques1,2

Aims: Neurocognitive impairments are commonly considered a core feature of Schizophrenia. The aim of this study was to compare the performance between schizophrenic patients and healthy matched controls in different cognitive measures derived from the Portuguese adaptation of the Wechsler Adult Intelligence Scale 3rd Edition (WAIS-III).

Methods: Sample consisted of 37 Portuguese patients diagnosed with schizophrenia and 37 normal controls, matched for the following categories: age, education and geographic region. All subjects were assessed with a neurocognitive battery which comprised both verbal (Arithmetic, Vocabulary, Digit Span, and Letter-Number Sequencing) and performance subtests (Picture Completion, Digit Symbol - Coding, and Symbol Search) from the WAIS-III. Controls were part of a broader study designed to adapt the WAIS-III to Portugal.

Results: Patients performed significantly worst than controls in most of the subtests. The only exception occurred with the Vocabulary subtest, in which no significant differences were found. The subtests in which schizophrenic patients showed the most pronounced deficits were Picture Completion, Arithmetic and Digit Symbol - Coding.

Conclusions: The results confirm the presence of generalized cognitive impairments in schizophrenia. These deficits appear to be more prominent in performance tests than in verbal tests. The inexistence of impairment in the Vocabulary subtest should be carefully examined in further investigations. However in the project Measurement and Treatment Research to Improve Cognition in Schizophrenia the cognitive dimension Verbal Comprehension was excluded for being considered to be extremely resistant to change.

3. Susana Aguiar2,3

Aims: Social cognition has been proposed as one possible mediator between neurocognition and functional outcome in Schizophrenia. Social cognition is a broad construct including different domains such as emotion processing, social perception and theory of mind. In this study we will focus on emotion recognition in order to analyse the associations between cognitive skills, facial emotion recognition and psychosocial functioning and to determine if emotion recognition mediated the relationship between cognition and psychosocial functioning.

Methods: 30 Portuguese patients diagnosed with Schizophrenia were selected to participate in the study. Participants were assessed on a test battery derived from the Working Memory and Processing Speed indices of WAIS-III and through a facial emotion recognition experiment. Life Skills Profile (LSP) was used to determine psychosocial functioning. Given the large number of parameters to be estimated we created a composite score of neurocognition based on the mean z-transformed scores of the cognitive measures.

Results: Neurocognition, emotion recognition and psychosocial functioning were significantly intercorrelated. Through the causal steps method developed by Baron and Kenny we observed that controlling for the mediator (emotion recognition) the association between neurocognition and psychosocial functioning decreased. Sobel test revealed that emotional recognition better mediated the Communication dimension of LSP than the total LSP score.

Conclusions: There was found some evidence to support emotion recognition as a mediator of psychosocial functioning. Communication was better mediated by emotional recognition than general psychosocial function, since the latter include other areas of function such as self-care skills, which are not dependent of social interaction.

REMISSION IN PSYCHOTIC CHRONIC PATIENTS: DIFFERENTIAL PROFILE IN THE USE OF LONG-ACTING INJECTABLE ANTIPSYCHOTICS

INSTITUTIONS
1. E.S.M.D MACARENA CENTRO, Area Salud mental Virgen Macarena, Seville, Spain

AUTHORS
1. Samuel Leopoldo Romero Guillena, Dr., forqueta@terra.es
2. Juan Luis Velez Noguera, Dr.
3. Raul Fernandez-Villamor Ortiz, Dr.
4. Carolina Parra Gonzalez, Mrs.

Aims/Objectives: The aims of this project is to investigate whether there is a significant difference in the rate of remission, as defined by Dr. Andreasen et al., in group of patients treated by either Long-Action Injectable Risperidone (LAI Risperidone) or conventional depot: Flufenazine decanoate or Zuclopentixole decanoate. Analyze the status of antipsychotic monotherapy and/or polytherapy based on the treatment received.

Methods: 46 schizophrenic patients diagnosed according to the ICD 10 (International Classification of Diseases) were assigned 3 different treatments: 1) 21 patients treated with long-acting injectable Risperidone (LAI Risperidone), 2) 8 patients treated with Flufenazine decanoate and 3) 17 treated with Zuclopentixole decanoate. 24 months of follow up. Remission Criteria (Andreasen et al., 2005), Global Clinical Impression (CGI-I) and Global Activities Evaluation (EEAG) scales were measured.

Results: Patients treated with LAI Risperidone experienced a statistically significant increase in the rate of remissions (p<0.05) and the rate of patients under a monotherapy treatment (p<0.01) all compared to the group of patients who received the conventional depot either Flufenazine decanoate or Zuclopentixole decanoate.

Conclusions: Long-acting risperidone can increase substantially the level of remission in schizophrenic patients. Long-acting risperidone injection enhances the use of antipsychotic monotherapy.

These circumstances would improve treatment compliance, enhance compliance and lead to a better quality of life and better outcome.

PSYCHOSOCIAL REHABILITATION OF CHRONIC PSYCHOTIC PATIENTS ACCORDING TO THE CLUBHOUSE MODEL

INSTITUTIONS
1. Military Medical Academy, Psychiatric Department, Belgrade, Serbia and Montenegro

AUTHORS
1. Radomir Samardzic, radsam@eunet.yu
2. Zeljko Spiric, zspiric04@yahoo.com
3. Tanja Stojanovic, radsam@eunet.yu
4. Gordana Mandic Gagic, mandig468@yahoo.com
5. Natasa Milosevic, zspiric04@yahoo.com
6. Dragan Krstic, zspiric04@yahoo.com

Aims: This paper represents analysis of long-term psychosocial rehabilitation methods and effects on patients with chronic psychotic disorder.

Method: The Clubhouse model was accepted in Day hospital of Military Medical Academy twenty years ago. Patients attend Club’s gatherings every Wednesday in the same place. The rehabilitation programme was being organised and led by a psychiatrist, psychologist, social worker and a nurse. Therapy consists of individual and group psychotherapy; psychoeducation of patients and their family members as well as occasional art therapy and group drawing analysis. Group therapy is one our long, with an average number of twelve patients. Most commonly used techniques are supportive psychotherapy, psychoeducation and some elements of cognitive-behavioural therapy. One of the group therapy characteristics is the patients’ initiative for selecting the group session topics.

Results: Analysing those topics, we have come up with the most popular subjects for the patients: coping with stress, emotions, characteristics of patient’s personality, psychotic symptoms, interpersonal communication and quality of life. Even so, the patients have shown the biggest interest for quality of life, personality and emotions, and the smallest for symptoms.

Conclusion: The psychosocial rehabilitation applied has the prevention of psychotic disorder relapse for its goal. It is also helping patients to have better insight into their illness, expand psychosocial activities and achieve better quality of life. This type of psychosocial rehabilitation has had very good effect on patients due to low rate of relapse, especially on those patients who were regular visitors to the Club.

AUTHORS
1. Erkan Baysak¹, Mr, MD, erkanbaysak@gmail.com
2. Duygu Cabuk¹, Mrs, MD, fduygu@gazi.edu.tr
3. Aslihan Sayın¹, Mrs, MD, aslihansayin@yahoo.com

Introduction
Ekbaum syndrome, also known as delusional parasitosis (DP), is a rarely seen disorder; which is characterized with a persistent belief that one's own body is infected by worms, insects or parasites. DP can be seen due to an underlying psychiatric or physical disorder (secondary DP), as well as without predisposing factors (primary DP). In this report, we present a case of a patient with secondary DP.

Case Report
A 55 year old woman, with a known diagnosis of paranoid schizophrenia for 30 years, was hospitalized with complaints of having insects in her face and hair. Her blood screening and cranial MRI was found to be normal. The initial SANS and SAPS scores were 58 and 61 respectively. She was consulted to dermatologist because of the lesions on her hands due to repeated hand washing, in consequence of her belief that insects are scattered on her hands. Risperidone 2-12 mg/day was used for 3 weeks, but since there was no significant change on her clinical state, her drug was changed to amisulpride and the dose was increased to 1200 mg/day. At the follow up, the persistent belief of the patient about having insects on her body, had disappeared completely.

Discussion
We think that this case is of particular interest, since it is the first one to report the successful treatment of DP with amisulpride. In recent studies atypical antipsychotic drug administration is being emphasized in the treatment of DP, because of the serotonin receptor blockage effects.

3. Mohammed H. Ahmed¹, Dr., MD

Aim: To determine characteristics and symptom profile of psychotic disorders in middle aged patients attending psychiatry clinics of Ahmadu Bello University Teaching Hospital

Methods: 160 patients with non organic psychotic disorders above forty-five years were admitted into the study. Socio-demographic questionnaire, BPRS, SANS, SAPS, MMSE and AIDS were used to elicit presence of psychotic symptoms, Negative and Positive symptoms, cognitive changes, Abnormal involuntary movements and generate ICD-10 diagnosis respectively.

Result: A total of one hundred and sixty subjects were studied, 61% were females (61.3%), mean age was 49.8±5.6, 70% were married, 63% had polygamous marriage, 85% had children, 55% were employed, and 65% adhered to medications. 58% had schizophrenia 17.5% had bipolar affective disorder, 8.8% had depressive disorder and 7.5 had persistent delusional disorder. Delusions were the most common psychotic symptoms, delusions of reference and persecutions were the most common type of delusions. Auditory hallucinations were most common type of hallucinations. Subjects manifested both positive and negative symptoms, schizophrenic subjects manifested negative symptoms more than others. Cognitive decline was not common but social impairment was more in subjects with schizophrenia.

Conclusion: Schizophrenia still represents the most common functional psychotic disorder that presents to the hospital in midlife and the outcome is better in this part of the World.

AUTHORS
6. Joachim Cordes5, 7. Lars Eriksson6, 8. Enrico Smeraldi7

Aims: To investigate if risperidone long-acting injectable (RLAI) provides better efficacy maintenance over 2-years, as measured by the time-to-relapse, in comparison to oral atypical antipsychotic quetiapine.

Methods: In this open-label, active-controlled, multicenter, 2-year trial, patients with schizophrenia or related disorder were switched from stable treatment with oral risperidone, olanzapine, or oral conventional neuroleptics to randomly-assigned RLAI or quetiapine. Symptomatically stable patients on a stable dose of an antipsychotic for ≥4 weeks were enrolled. Subjects were evaluated with the Positive and Negative Syndrome Scale among other evaluations at baseline. Primary efficacy evaluation was time-to-relapse. Safety evaluations included adverse events (AEs) monitoring, Extrapyramidal Symptom Rating Scale (ESRS), clinical laboratory tests, and vital signs.

Results: A total of 710 subjects were randomized. Mean time since psychiatric diagnosis was 10 years. Reasons for switching included: AEs and insufficient efficacy with negative, positive, or general symptoms. Baseline demographics were similar between treatment groups. Relapse occurred in 16.5% treated with RLAI and 31.3% with quetiapine. Risk-of-relapse was significantly reduced in subjects treated with RLAI compared with quetiapine (p<0.0001). RLAI and quetiapine were well-tolerated. Weight gain affected <10% of subjects treated with either RLAI or quetiapine. Extrapyramidal AEs occurred for 10% with RLAI and 6% with quetiapine. ESRS total scores decreased similarly after switching to either RLAI or quetiapine. Possibly prolactin-related AEs were more common with RLAI than oral atypicals.

Conclusion: Subjects enrolled in this relapse prevention trial were typical of patient samples with schizophrenia or related disorders. RLAI and quetiapine were well tolerated.

6. Msadek Azzouz3, Mr, MD
7. Riadh Bouzid2, Mr, MD

Aim: Some reports indicated a possible relationship between celiac disease and schizophrenia with improvement of psychotic symptoms after a gluten-free diet. The purpose of the present study was to assess the prevalence of celiac disease in a group of Tunisian schizophrenic patients in comparison to a control group.

Methods: Eighty nine schizophrenic outpatients diagnosed according to ICD 10 criteria, as well as 78 age and sex matched control subjects were included in the study. All patients and controls gave their informed consent. History of abdominal pain, chronic diarrhea as well as the presence of microcytic anemia was checked in all patients. Besides, IgA and IgG antitransglutaminase antibodies (ATG) were assessed in all patients and controls. Antiendomysium antibodies (AE) were assessed every time ATG were positive.

Results: History of abdominal pain was found in 30 schizophrenic patients (33.7%), chronic diarrhea in 19 cases (21.3%) and microcytic anemia were present in 5 cases (5.6%). Three patients (3.4 %) had IgA ATG, only 2 amongst them were IgG ATG positive. As for controls, 2 (2.6%) presented IgA ATG and no IgG ATG were detected. There were no significant difference in the prevalence of ATG between patients and controls. No AE were found, thus excluding the diagnosis of celiac disease in both groups.

Conclusion: Like in other studies, the present results do not support association between celiac disease and schizophrenia.

8. Snezana Manojlovic, Dr, PhD, ttomas@eunet.yu

Objective: Lipid disorders are common in the general population. However, little information is available regarding the prevalence and incidence of lipid disorders in patients with serious mental illnesses. Recent reports suggest a temporal association between lipid disorders and the use of atypical antipsychotics. The objective of the present study was to investigate serum lipid changes in patients with schizophrenia or related disorders who received treatment with atypical antipsychotics.

Methods: This was a 6 months prospective study, which was active controlled, in patients with DSM-IV schizophrenia, who were drug-free before hospitalization. Tests included nonfasting total cholesterol, HDL, LDL fractions and triglycerides, which were determined from blood in the same hospital laboratory. The data was performed at baseline and at weekly intervals during the study.

Results: The results we receive show a great effect of atypical antipsychotics on serum lipids. Decrease in all fractions of serum lipids was observed, with pick on 3 months after start point. Also, there were small differences in liability for serum lipids between different antipsychotic agents.

Conclusion: Atypical antipsychotic medication is associated with a great risk of metabolic abnormalities such as dislipidemia. This is potential risk of cardiovascular diseases and diabetes.

6. Georgios Kaprinis

Objective: Frontal lobe dysfunction has been considered as a core feature in schizophrenia. For the evaluation of this impairment, time-consuming neuropsychological batteries are needed. Recently, Dubois et al (2000) presented a short battery (“Frontal Assessment Battery”-FAB) for assessing frontal lobe function in patients with neurological disorders. To evaluate the clinical usefulness of this battery (FAB) in patients with schizophrenia, we performed both FAB and Stroop Color Word Test (SCWT), which is suggested to be a classical task of executive function.

Method: 60 schizophrenic patients and 30 sex and age-matched controls were included. FAB, SCWT and Mini Mental State Examination (MMSE) were performed in both groups. The FAB scores were compared with the performance in SCWT and correlated with education level, age and duration of disease.

Results: No difference in the MMSE scores between two groups was found. The FAB global score was significantly lower in the schizophrenia group compared to controls. In the patients group, the conceptualization and the inhibitory control subscores were negatively correlated with mistakes in color-naming task. The FAB total score, the mental flexibility and the programming subscores were negatively correlated with latencies in color-naming, color-reading and in color-word interference task of SCWT. Negative correlation between the FAB scores and the age and duration of disease was also evident.

Conclusion: The FAB is likely to be a useful and brief battery for assessing frontal lobe function in schizophrenia, as result from the comparison with SCWT.

6. Georgios Kaprinis1

OBJECTIVE: Frontal lobe deficits have often been reported in patients with schizophrenia. Recently, Dubois et al. (2000) reported a short bedside cognitive and behavioral battery (“Frontal Assessment Battery”-FAB)1 for assessing frontal lobe function in patients with neurological disorders. We hypothesized that cognitive functions of frontal lobe in schizophrenia could be evaluated with this battery.

METHOD: 60 patients with schizophrenia and 30 sex and age-matched controls were included. We performed Fab and Mini Mental State Examination (MMSE) in both groups and we correlated the scores of six subtests and the total Fab score with handedness, education level, age and duration of disease.

RESULTS: The Fab global score was significantly lower in the schizophrenia group compared to controls. There was negative correlation between the Fab scores and their age and duration of illness in the schizophrenia patients. Correlation between Fab scores and MMSE scores was taken into account in both groups.

CONCLUSION: The Fab is likely to be a useful and brief battery for assessing frontal lobe function in schizophrenia patients.

5. Yong Woo Kim1, Dr., MD
6. Borah Kim1, Dr., MD

Objectives: Schizophrenia is a chronic disorder usually characterized by relapses alternating with periods of full or partial remission. First-episode schizophrenia usually respond well to treatment, but relapse is frequent during the first years of the illness and may be associated with clinical deterioration. To reduce relapse and rehospitalization rates, new long-acting injectable antipsychotics may be needed in some patients with first-episode schizophrenia. Therefore, we examined whether long-acting injectable risperidone could reduce relapse rate among outpatients with first-onset schizophrenia.

Methods: We conducted a prospective study of 49 subjects with first-episode schizophrenia. We nonrandomly assigned 21 patients with first episode schizophrenia to long acting risperidone group and 28 patients to oral risperidone group. Relapse Rate, Medication Adherence, Brief Psychiatric Rating Scale (BPRS), Clinical Global Impression(CGI)and General Assessment of Functioning(GAF)was assessed.

Results: Long acting risperidone group showed lower relapse rate compared to oral risperidone group (1-year relapse rate: 19% Vs 48%; 2-year relapse rate: 23% Vs 87%). Medication compliance was higher in long acting risperidone group than in oral risperidone group (85.7±21.2 Vs 54.5±32.1 %). Cox proportional survival analysis showed that medication compliance was most significant predictor of first relapse in first episode schizophrenia. Large multicentered trial is needed.

Conclusion: We suggest that long acting injectable risperidone could be more effective in maintaining medication adherence than oral risperidone and The most significant predictor of relapse is noncompliance in first episode schizophrenia. Large multicentered trial is needed.

ITAREPS presents a mobile phone-based telemedicine solution for weekly remote patient monitoring and disease management in schizophrenia and psychotic disorders in general. The programme provides health professionals with home telemonitoring via a PC-to-phone SMS platform that identifies prodromal symptoms of relapse, to enable early intervention and prevent unnecessary hospitalizations. Its web-based interface offers the authorized physician a longitudinal analysis of the dynamics and development of possible prodromes. Previous one-year clinical evaluation of the programme effectiveness in 45 patients with psychotic disorder showed significant 60% decrease in the number of hospitalizations. This work presents data from a two-year mirror-design follow-up evaluation of the programme’s clinical effectiveness in 73 patients with psychotic illness. There was a statistically significant 77% decrease in the number of hospitalizations during the mean 396.8 ± 249.4 days of participation in the ITAREPS, compared to the same time period before the ITAREPS entry (Monte Carlo, exact test, 2-tailed, Z=4.86, p = 0.00).

The ITAREPS presents a novel approach towards relapse prevention. The programme offers affordable solution to face the challenges of frequent rehospitalisation and relapses in patients with schizophrenia and psychotic disorders in general.

Aims: Schizophrenia is one of the most frequent mental diseases. The probability of being taken ill with this psychosis among the whole population is 1%. Frequent hospitalization of schizophrenic patients prevent them from normal and effective functioning in a society [1]. Conducted research had an aim to isolate and define the risk factors of re-hospitalization among schizophrenic patients.

Methods. In the research, the authors used their own questionnaire which provided the demographic, social and medical data. The research were based on archival case histories of schizophrenic people who were the patients of a mental hospital. The research was conducted among 65 people (27 women, 38 men) who were hospitalized more than 15 times in the schizophrenic treatment.

Results. Psychiatric rehospitalizations in schizophrenia are conditioned not only by medical factors connected with the disease itself, but also by demographic and social factors.

Conclusions. 1) The decisive role in rehospitalization of schizophrenic patients plays a small availability of alternative psychiatric care in the patients’ dwelling place as well as the lack of regularity in the continuation on treatment after leaving the mental hospital. 2) Patients’ family status, relationship with family and friends and the level of acceptance and understanding of their disease decline the risk of rehospitalization. 3) The greatest risk of rehospitalization is among people from the lowest class - lonely, young men with primary or vocational secondary education, having no permanent employment.

Objectives: The neurodevelopmental hypothesis of schizophrenia (SCH) is based on the interactions of candidate genes with environmental insults during pregnancy. With regard to the effects of maternal infectious processes on the manifestation of SCH in early adulthood, this study was aimed at (a) the late behavioural consequences of early neonatal exposure to retroviral glycoprotein (gp120) and capsid protein (CA) and (b) evaluating chronic antipsychotic treatment on the psychosis-like behaviour induced by these protein [1].

Methods: Male rats were injected (i.p.) with gp120 or CA between postnatal day (PD) 4 and 8. Adult rats were assessed in terms of the prepulse inhibition (ppi) of the acoustic startle response (asr) and of locomotor activity. Sixty-day-old rats were treated with haloperidol (HAL; 1 mg/kg) and/or with clozapine (CLZ; 20 mg/kg) added to the standard diet for the next 30 days. Results: Unchanged locomotor activity was observed in both experimental rat groups, but a ppi impairment was found in both gp120- and CA-treated rats. HAL significantly depressed locomotor activity in all tested groups. A higher amplitude of ASR was found with both HAL and/or CLZ treatment in the gp120 group. A reduction in ppi deficiencies was documented in the group treated with gp 120/HAL.

Conclusions: Neonatal administration of retroviral gp120 and CA alters the ppi of asr in adult rats and this negative effect can be attenuated by chronic (per os) treatment with HAL and/or CLZ.

Supported by grant IGA MChR no. Nr8797-4.

Objective: To evaluate clinical and functioning outcomes of risperidone long-acting injection (RLAI) treatment in patients with schizophrenia enrolled in the electronic-Schizophrenia Treatment Adherence Registry (e-STAR) from Czech Republic and Slovakia.

Methods: e-STAR is an international, long-term, prospective, observational study of patients with schizophrenia who commence RLAI treatment. Data are collected retrospectively for 1 year and prospectively every 3 months for 2 years. Clinical outcomes were measured by Clinical Global Impression-severity (CGI-S) scale and patient functioning was assessed using Global Assessment of Functioning (GAF) scale. This interim report is based on data from patients who have completed their 18-month follow-up visit.

Results: To date, total of 1324 patients have been enrolled in e-STAR from the Czech Republic and Slovakia; 296 patients with at least 18-months of data available (97.3% still on RLAI) were included in this analysis. Of the 296 patients, 53.7% were male with a mean age of 37.6±12.0 years and a mean time since diagnosis of 9.6±9.0 years. Mean CGI-S score significantly decreased from 4.6±1.1 at baseline to 2.9±1.0 at 18 months (p<0.001). Proportion of patients with not ill/very mild/mild illness increased from 13.5% to 75.6% and that of patients with marked/severe/extremely severe decreased from 48.8% to 6.3% (p<0.001) compared to baseline.

Meanwhile, patient global functioning has significantly improved as the mean GAF score increased significantly from 49.9±15.2 at baseline to 73.8±14.5 at 18 months (p<0.001).

Conclusions: Significant improvements in disease severity and functioning from baseline were observed during 18-month treatment with risperidone long-acting injection in patients with schizophrenia.

Aims/Objectives: The aim of the present study is to investigate the relationship between cognitive function and clinical variables in people with schizophrenia.

Methods: The subjects were forty-nine stabilized outpatients with schizophrenia (DSM-IV). Their mean age was 39.7 (SD=11.7) years. All subjects gave written informed consent to participate in the research. Cognitive function was evaluated using the Brief Assessment of Cognition in Schizophrenia (BACS). Clinical symptoms were assessed using the Positive and Negative (PANSS), the Calgary Depression Scale for Schizophrenia, and the Drug-Induced Extrapyramidal Symptoms Scale (DIEPSS). Spearman rank correlations were calculated to examine the relationships between the BACS measures (Verbal Memory, Working Memory, Motor Speed, Verbal Fluency, Attention, and Executive Function) and clinical variables.

Results: Dose of neuroleptics was significantly correlated with Verbal Memory score (r= -.36, p<.05) and Executive Function score (r= -.30, p<.05). The PANSS negative syndrome scale score was significantly correlated with Verbal Memory score (r= -.41, p<.01), Working Memory score (r= -.40, p<.01), Attention score (r= -.46, p<.01), and Verbal Fluency score (r= -.47, p<.01). In addition, the DIEPSS score was significantly correlated with Verbal Memory score (r= -.40, p<.01), Working Memory score (r= -.42, p<.01), Attention score (r= -.50, p<.01), Verbal Fluency score (r= -.45, p<.01), and Executive Function score (r= -.29, p<.05).

Conclusion: These results suggest that cognitive function might be influenced by extrapyramidal symptom, negative symptom, and dose of neuroleptics in people with schizophrenia.

Objective: To determine the prevalence and conditions of pharmacoresistance (PR) of schizophrenic men in clinical episodes.

Material: 100 schizophrenic male patients aging from 17 to 49 (mean age 24±2). The first episode of paranoid schizophrenia (PS) was diagnosed in 54 cases, schizoaffective disorder (SA) in 46 cases. PR signs were registered in 42 cases, PR in 30 cases (PS 55.5%), and SA in 12 cases (26%).

Results: PR manifested itself as reaction deficiency not less than in 3 successively prescribed neuroleptics, as a minor or unstable therapeutic effect, as frank by-effects, as pseudo-remission. The psychotic state duration prior to the care period was 1 month to 4 years, due to which 43% of the patients were formerly repeatedly treated as outpatients and inpatients. Inadequate therapy at various treatment stages was revealed in 27 cases. The therapy included: resistance overcoming, reduction of the episode. Qualitative and stable remission (catalepsy making more than 1 year) was obtained in 87% of cases.

Conclusion: The risk of pharmacoresistance of schizophrenic men in clinical episodes is high; its conditions and causes may be classified into pathogenetic and iatrogenic. Pharmacoresistant schizophrenia may be treated with positive results.

Aims/Objectives: Since the introduction of the newer atypical antipsychotics in the nineties, the prevalence of antipsychotic polypharmacy in patients with schizophrenia tripled suggesting inadequate efficacy or treatment resistance. This was paralleled by a tenfold increase in costs over the period 1993-2003 without, however, a clearly demonstrated improvement of efficacy. Remarkably, the prescription of clozapine did not increase. These trends are reflected by the number of publications about the rationale for augmentation strategies in case of lack of responsiveness to clozapine.

Methods: A systematic search of the literature was performed into augmentation studies with clozapine.

Results: Over the past decade about 40 open studies have been published in which clozapine was augmented with another antipsychotic, mostly risperidone or amisulpride. Of these cases reports, nearly all described a positive outcome. Seven controlled studies have been published using augmentation of clozapine with sulpiride (n=1), amisulpride (n=1), amisulpride and quetiapine (n=1) and risperidone (n=4), including 266 schizophrenic patients, partially unresponsive to clozapine prescribed in a daily dose of 400-550 mg. In only 3 of these studies the plasma concentration of clozapine was measured that ranged from 400-800 µg/l. None of these studies showed a relevant improvement. In one study with sulpiride a decrease on the BPRS of 21 % was noted after 10 weeks of combined treatment.

Conclusions: The results are flawed by the lack of information on the plasma concentrations of clozapine in most of the studies. There is no database to conclude that augmentation of clozapine with other antipsychotics is clinically relevant.

Gamma band frequencies have been associated with the sensory encoding and processing of auditory information, with auditory hallucinations (AHs) being associated with excessive gamma. This finding may reflect a hyperconnectivity, which in turn could be associated with excessive processing and impaired sensory integration. Many imaging studies have implicated also the superior temporal cortex (STC), the anterior cingulate cortex (ACC) and the prefrontal cortex (PFC) in AHs. This study used gamma band oscillations to examine source density (GSD) in 12 hallucinating (HP) and 12 non-hallucinating (NP) patients (and 12 controls) during passive recording conditions. Furthermore, as a number of studies have suggested that hallucinations worsen in the presence of speech, GSD was also examined in response to external speech presented during background noise and silence conditions. Low resolution electromagnetic topography (LORETA) analysis was used to estimate GSD and its distribution in the cortex. In the silence condition, HPs exhibited less GSD in the left temporal regions, including the STG. Conversely, NPs exhibited less GSD in the right temporal regions. In the speech only condition, HPs showed greater GSD in the medial and superior frontal regions (bilaterally) and in the right anterior and posterior cingulate cortices. NPs exhibited greater GSD in the left inferior and superior parietal regions, in the speech without noise condition only. Because gamma synchrony establishes the neural communication necessary to “bind” sensory components into a unified percept, our findings suggest that the hallucinations may be influenced by binding within two separate neurocircuitries.

Improvements of cognitive and social functioning have been reported in patients with schizophrenia participating in rehabilitation programs (1). This study was aimed to evaluate verbal memory performance in schizophrenic subjects, before and after a cognitive rehabilitation program, and the associated electrophysiological changes.

Twenty-one subjects (14 males), with mean age (±sd) of 35.8 (±5.6) years, were enrolled. All of them received a DSM-IV diagnosis of schizophrenia and underwent a six-month rehabilitation program. Event-related potentials were obtained from 30 electrodes, while subjects were engaged in a continuous word recognition memory task, in which they were asked to press two different buttons when “old” (already recognized) or “new” words were presented. Amplitude and latency measures for N1 (80-350 msec), P3 (250-550 msec) and N4 (400-700 msec) components were obtained. Extensive psychopathological and neuropsychological evaluations were also carried out.

Mean correct hits rate was 52.37%, errors and omissions rates were 24.44% and 23.19%, respectively. Mean (±SD) reaction time for correct hits was 750.94 (±182.07) msec. Preliminary multivariate analyses of variance showed, at baseline, greater N1 amplitude (F1,20=5.01; p<0.03) and latency (F1,20=8.67; p<0.01) for “new” stimuli, with respect to the “old” ones. Only for the recognized words, N1 latency correlated positively with verbal fluency (r=0.46; p<0.05) and N1 amplitude correlated negatively with depression (r=-0.55; p<0.05) and motor slowing (r=-0.52; p<0.05).

Our data suggest that subjects with schizophrenia pay greater attention to newly presented verbal stimuli and that changes in verbal memory and attention may influence their symptoms and social functioning.

It is well documented that religion has an impact on mental health. However, scientific research regarding the influence of religion on sexual experiences and sexual self-perception in mental health patients and healthy people is very scarce. Therefore, our goal was to research how and in what measure religious views of both mental health patients and healthy people influence their sexual functions and sexual self-perception.

Research was conducted on 100 patients suffering from schizophrenia and 100 patients suffering from depression, while 100 healthy individuals served as the control group. In order to research the aspects of sexual self-perception we used Bezinovic’s questionnaire and Arizona sexual experience scale (ASEX) to research the aspects of sexual intercourse.

Results show that roman-catholic patients suffering from schizophrenia experience greater sexual satisfaction than eastern-orthodox or atheist schizophrenic patients. Among patients suffering from depression of differing religious views there were no significant differences regarding sexual satisfaction or the aspects of sexual self-perception. Furthermore, there is a significant difference among healthy individuals when taking into consideration religious views. We established that Muslims have a significantly stronger sexual drive then atheists, roman-catholic or eastern-orthodox individuals. Compared to roman-catholic and eastern-orthodox individuals, atheists have better consciousness of their own sexuality. Religious views have an influence on sexual functioning and sexual self-perception in both mental health patients and healthy individuals. Further research on a bigger sample of participants - not only of those religious denominations covered in this research, but also of those less present in our society - is needed.

**THREE- YEARS REHOSPITALIZATION RATES OF PATIENTS DISCHARGED WITH HALOPERIDOL OR RISPERIDONE OR CLOZAPINE**

**INSTITUTIONS**
1. University of São Paulo, Department and Institute of Psychiatry, São Paulo, Brazil

**AUTHORS**
1. Ana Paula Werneck¹, Dr, MD, anapwc@uol.com.br
2. Helio Elkins¹, Dr, Phd, helkis@usp.br

Based on previous review we hypothesize that second generation antipsychotics are superior to conventional antipsychotics for preventing rehospitalizations. Hence, the aim of this study was to observe 3-year rehospitalization rates of patients with schizophrenia discharged on a regimen of haloperidol, risperidone, or clozapine. Data were collected from charts and hospital database. Survival curves were estimated by the product-limit formula and Cox regression models was used to analyze covariates. A total of 96 patients entered the selection and at 3 years follow-up the percentage of patients remaining discharged were 74% for haloperidol, 59% for risperidone and 84% for clozapine. There were no significant differences in re-admission rates among the three groups. Age, gender, age of onset of symptoms, length of illness, number of previous hospitalizations, length of hospitalization and length of follow-up were not associated with the risk of rehospitalization. The results demonstrate lower rehospitalization rate for clozapine than haloperidol, and lower rate for haloperidol than risperidone. Conclusions drawn from this study must be tempered according to the limitation of the methodology used. Patients were not randomly assigned; the comparison involves clozapine, a drug defined for treatment resistant schizophrenia and at the time of the study risperidone was used for patients who hadn’t previously responded to conventional antipsychotics and it is possible that such were also treatment resistant, thus representing a more severe population. Nevertheless, all covariates and those thought to have impact on time to readmission were not related to the risk of being readmitted in the Cox regression model.

**MARS - USEFUL COMPLIANCE SCALE FOR SCHIZOPHRENIC PATIENTS**

**INSTITUTIONS**
1. Institute of Psychiatry and Neurology, Third Department of Psychiatry, Warsaw, Poland

**AUTHORS**
1. Adam Wozniak¹, Dr, MD, wozni@ipin.edu.pl

The aim of this study was to examine psychometric properties of the polish language version of Medication Adherence Rating Scale (MARS) – new compliance scale constructed with the aim of greater validity and clinical utility (Thompson K., Kulkarni J., Sergejew A.A. Reliability and validity of a new Medication Adherence Rating Scale (MARS) for psychosis. Schizophr Res 2000, 5; 42: 241-247).

60 inpatients with ICD-10 schizophrenia were assessed on MARS, DAI-10, UKU and PANSS. Patients were divided into two groups - those with MARS total score < 7 were classified as non-compliant. There were no differences between compliant and non-compliant group in age, education, and duration of illness, number of hospitalizations. Non-compliant group had higher score on uncooperativeness (G8) and lack of insight (G12) items on PANSS (3.59±1.24 vs 2.57±1.17 and 4.96±1.34 vs 3.87±1.21 respectively; p<0.002). And lower score on DAI-10 (13.9±2.4 vs 16.8±2.6; p<0.0001). MARS total score correlated negatively with excitement factor of PANSS (r= - 0.39, p=0.002).

Polish version of Medication Adherence Rating Scale (MARS) has good reliability, validity and it is a useful tool for clinical assessment of compliance in schizophrenic patients. Psychometric properties of MARS are better then Drug Attitude Inventory (DAI-10).

PAIN IN SCHIZOPHRENIA

INSTITUTIONS
1. Institute of Psychiatry and Neurology, Third Department of Psychiatry, Warsaw, Poland

AUTHORS
1. Adam Wozniak, Dr, MD, wozni@ipin.edu.pl

Psychiatric literature contains many reports of unexpected pain reactions in schizophrenia. Clinicians have observed, that most patients with schizophrenia appear to be relatively insensitive to physical pain and bodily discomfort. In surgical literature we can find reports of schizophrenia patients with atypical pain reaction during extremely painful acute medical conditions. There are suggestions that analgesia in schizophrenia may lead to the misdiagnosis of potentially serious health problems. Yet, the phenomenon of pain insensitivity in schizophrenia remains unclear. To explore this issue, we examined pain sensitivity in 20 inpatients with ICD-10 schizophrenia and healthy adults using the Cefar Painmatcher, electric pain stimulator. There were no differences in general characteristic between patients with schizophrenia and control group. Patients with schizophrenia showed elevated pain thresholds and pain tolerances to electric stimulation.

SMOKING IN SCHIZOPHRENIA - RELATIONSHIP TO PSYCHOPATHOLOGY AND SIDE-EFFECTS

INSTITUTIONS
1. Institute of Psychiatry and Neurology, Third Department of Psychiatry, Warsaw, Poland

AUTHORS
1. Adam Wozniak, MD, wozni@ipin.edu.pl

There is an increased interest in smoking among patients with schizophrenia. It was suggested that frequency of smoking may be associated with positive and negative symptoms as well as may be a self-help strategy in dealing with side-effects of medications. The aim of our study was to examine the relationship between smoking and psychopathology and side-effects in a sample of 60 patients with ICD-10 schizophrenia, hospitalized due to exacerbation of psychosis. Psychopathology was assessed with PANSS, side effects were measured with UKU. Smoking status was determined and Fagerstrom test was administered to all smoking subjects. 58,3% patients were smoking and 36,6% were smoking more than 10 years. There were no differences between smokers and non-smokers on PANSS total as well as positive, negative and depressive factors of PANSS. The only difference was excitement factor were smokers scored higher (p<0.02). There were no differences in side effects between two groups.

Objectives: The purpose of this study was to assess the effect of a weight reduction program designed for schizophrenic inpatients and to compare these patients with a randomized control group. The effects of the weight loss were assessed especially with regard to obesity-related quality of life.

Method: Fifty-one obese schizophrenic inpatients were enrolled in a 12-week, randomized weight reduction program. Thirty-two patients were randomly assigned to an intervention group in which they received weight management program. Nineteen patients were allocated to a control group in which they received usual clinical inpatient treatments. Body weight, body mass index (BMI) and quality of life scales such as short Form of Medical outcome study (SF-36), Korean version of Obesity-related Quality of life Scale (KOQOL) were evaluated during 12-week period. All assessments were done at baseline, week 4, 8 and 12.

Results: Sixteen of 32 (50%) patients in intervention group and 12 of 19 (69.4%) patients in control group completed this study. We found significant differences in weight (p<.05) and BMI (p<.05) change from baseline to endpoint between intervention and control groups. After completion of the weight management program, there were significant differences on the physical Component summary of SF-36 (p<.05), total scores, (p<.05), Psychosocial Health (p<.01), Physical Health (p<.05) and Diet subscales (p<.05) on the KOQOL between intervention and control group.

Conclusion: The weight reduction program was effective for weight reduction in schizophrenic inpatients. In addition, it showed the improvement of the obesity-related quality of life.

Objective: This study was aimed to investigate the prevalence of metabolic syndrome (MS) and associated characteristics in schizophrenic inpatients.

Method: In this cross-sectional study, 214 inpatients with schizophrenia or schizoaffective disorder defined by DSM-IV criteria were included. Prevalence of MS was assessed based on the Asian-Pacific Criteria of National Cholesterol Education Program (NCEP, Adult Treatment Protocol, ATP-III).

Results: Prevalence of MS was 22.9% in our sample. Metabolic syndrome was associated with male sex, but not with duration of illness, current use of antipsychotic medications. Compared with patients without metabolic syndrome, patients with metabolic syndrome had higher risk for cardiometabolic morbidity. Of the individual cardiometabolic risk factors, waist circumference (65%) and HDL-cholesterol (54.7%) were more common than triglyceride (29.4%), blood pressure (8.9%) and blood glucose (5.1%).

Conclusion: Although prevalence of MS in schizophrenic inpatients was common in our sample, it was not quite high than general population in Korea. But, it should be critical part of clinical management of schizophrenic patients to assess of the presence and monitoring of the MS.

DISCRIMINATION EXPERIENCES AND STIGMA OUTCOMES OF IN-PATIENTS WITH SCHIZOPHRENIA

INSTITUTIONS
1. Heinrich-Heine-University Düsseldorf, Department of Psychiatry and Psychotherapy, Düsseldorf, Germany

AUTHORS
1. Harald Zäske1, Mr., harald.zaeske@lvr.de
2. Anja E Baumann1, Dr., anjaesther.baumann@uni-duesseldorf.de
3. Wolfgang Gaebel1, Prof. Dr., wolfgang.gaebel@uni-duesseldorf.de

Aims: Social stigmatization is a severe burden for people suffering from severe mental illnesses, especially from schizophrenia which is negatively associated with violent behavior and unpredictability. Nevertheless, quantitative data to what extent patients with a diagnosis of schizophrenia actually feel stigmatized in their everyday life is yet rare for Germany.

Methods: In the framework of the INDIGO-Study group (International Study of Discrimination and Stigma Outcomes in Mental Health, Thornicroft et al. 2007), an instrument has been developed for the assessment of discrimination experiences (DISC, Discrimination and Stigma Scale). The instrument comprises 51 items about discrimination experiences in different life domains and reactions to having a diagnosis of schizophrenia. The German version of the DISC was conducted with n=46 in-patients with schizophrenia.

Results: Important domains of stigma experiences are the social life (friendships, family), the workplace (finding or keeping a job), and mental health staff. The majority of the interviewed (61 – 76 %) stated that they react with anticipatory self-restraint (e.g., they stopped themselves from looking for close relationships) on the fact of having a diagnosis of schizophrenia.

Conclusions: Stigmatization and discrimination experiences are widespread in in-patients with schizophrenia in Germany. Further endeavors of antistigma work are needed to improve their situation, as projected within the German Alliance for Mental Health.

COGNITIVE IMPROVEMENT OF SCHIZOPHRENIC PATIENTS UNDER QUETIAPINE: A PRELIMINARY SINGLE-TRIAL ERP ANALYSIS

INSTITUTIONS
1. Medical School Hannover, Psychiatry, Socialpsychiatry and Psychotherapy, Germany

AUTHORS
1. Yuanyuan Zhang1
2. Martin Lehmann1
3. Amir Shobeiry1
4. Dörte Höfler1
5. Sönke Johannes1
6. Hinderk M. Emrich1
7. Detlef E. Dietrich1

The study aimed to explore by means of single-trial event-related potentials (ERPs), whether and how the medication change from older neuroleptics to quetiapine in schizophrenic patients leads to a significant cognitive enhancement. This single-trial ERP analysis allowed investigating attention and memory processes in single patient before and after treatment. Thirteen schizophrenic patients (mean age: 40.1 ± 13.5 y) were followed up for 16 weeks and assessed for changes of clinical symptoms and ERP-components P300 representing target detection processing and N400 indexing context integration in word recognition processes.

The mean scores of PANSS, MADRS, BF-S, SCL-90 and CGI-S at the end of study (week 16) showed significant improvements compared to the baselines (week 0) (p < 0.05). Three subjects had to be excluded from the ERP recording sessions because of excessive blink artefacts and movements. Regarding the P300 components of the target detection, there were significant increases of amplitudes in 5 of 10 patients (50%) at week 16 comparing to week 0. Regarding the N400 components of the word recognition, there were significant increases of amplitudes in 4 of 10 patients (40%) at week 16 comparing to week 0. No extrapyramidal symptoms as well as akathisia after quetiapine treatment were reported during the study.

These preliminary data suggested that quetiapine improved context integration and target detection processing in these patients. This technical procedure may help to differentially assess cognitive enhancements in each single patient.

7. John Davis4, Dr
8. Erminio Costa1, Dr, ecosta@psych.uic.edu

INTRODUCTION: Postmortem human brain studies suggest that in schizophrenia (SZ), there is a dysfunction of telencephalic GABAergic neurons that is characterized by the overexpression of DNA-methyltransferase1 (DNMT1), which is likely responsible for epigenetic promoter hypermethylation and the related downregulation of reelin and GAD67 genes.

OBJECTIVES: The goal of this study is to compare in peripheral blood lymphocytes (PBL) the expression of DNMT1 and Gad67 mRNAs, in control and schizophrenia patients (SZP).

METHODS: In PBL, DNMT1 and Gad67 mRNAs were measured using quantitative competitive RT-PCR and the values were compared to the housekeeping gene glyceraldehyde-3-phosphate dehydrogenase (G3PDH) mRNA.

RESULTS: The level of DNMT1 mRNA showed an increase greater than 2 fold (p<0.02) in the PBL of SZP (n=18) compared to NPS (n=16), whereas the levels of Gad67 mRNA were decreased by 30-40% (p<0.04) in the PBL of SZP (n=10) vs NPS (n=10). These changes are not influenced by age, gender, race and antipsychotics. Frequently, SZP are heavy cigarette smokers, we studied whether smoking affects DNMT1 expression. The higher levels of DNMT1 mRNA in SZP vs. NPS were present in both smoking and non-smoking groups. However, in the group of SZP, there was a trend for the few patients who had a heavier current cigarette smoking habit (>15 cigarettes /day) to have lower DNMT1 mRNA levels compared to those who smoked fewer cigarettes or to non-smoking SZP.

CONCLUSIONS: Measurements of DNMT1 and Gad67 mRNA content in lymphocytes should be investigated as a potential peripheral marker for the diagnosis of SZ.

CLINICAL REPORT OF MATRICS CONSENSUS COGNITIVE BATTERY (MCCB) FROM CHINA

INSTITUTIONS
1. Beijing Huilongguan Hospital, Peking University, Beijing, China

AUTHORS
1. Yizhuang Zou1, Mr., MD, PhD, yzouy@263.net
2. Jiefeng Cui1, Mr., MD
3. Jian Wang1, Mr., MD
4. Nan Chen1
5. Shuping Tan1, Mr., MD, PhD

Objective: To evaluate psychometric properties of MCCB (MATRICS Consensus Cognitive Battery) Chinese version.

Methods: 122 inpatients with schizophrenia who diagnosed with DSM-IV (84 males, and 38 females), received MCCB test and retest in 4 weeks.

Results: (1) Test-retest reliability of Category Fluency (CF), Trail Making-A (TMT), Symbol Coding (SC), Continuous Performance Test-Identical Pair (CPT-IP), Digital Span (DS), Spatial Span (SS), Hopkins Verbal Learning Test-R (HVLT-R), Brief Visual Memory Test-R (BVMT-R), Neuropsychological Assessment Test (MAZES) and Managing Emotion (ME) before and after 4 weeks were 0.75, 0.6, 0.85, 0.71, 0.73, 0.75, 0.62, 0.78, 0.71 and 0.68 respectively; Test-retest reliability of MCCB total score was 0.88, p<0.001; (2) Practice effects of CF, CPT-IP, HVLT-R, MAZES and ME are not significant (p>0.05), while TMT, SC, SS and BVMT-R have certain practice effect. Floor effects appear in SS (1.28%), and MAZES (1.72%), while ceiling effects in DS (0.85%); (3) Internal consistency: All subtests of MCCB appear significantly correlated with MCCB overall scores, p<0.001; (4) Tolerability and practicability are fine. Average administration time of MCCB is 58.2 minutes, with completing rate of 98%; (5) Differences between A/B alternate forms of HVLT-R, BVMT-R and MAZES are not significant (p>0.05).

Conclusion: MCCB may become a promising standard and sensitive clinical tool for assessing neuron-cognitive function in schizophrenia in China.

IMPARTING SPIRITUAL IDEAS IN TREATMENT MAY HELP FOR FAST AND SUSTAINED RECOVERY IN PSYCHIATRY

INSTITUTIONS
1. Calcutta Pavlov Hospital, psychiatry, Kolkata, India

AUTHORS
1. Asis Krishna Acharya¹, Dr., D.I.H., D.P.M, dr_asisacharya@yahoo.com

Objective: In majority of cases of treatment of psychiatry disorders, specially those of depression and anxiety related disorders, they are long, pharmacotherapy dependant, and sometimes not free from recurrence or exaggeration at times. Some other unique therapy are in quest to fill the gap to a reasonable degree which makes the suffering soul in peace and tranquility and the psychiatrist hopefully away from drugs indefinitely. Spirituality- a 4th dimension of health is less explored arena, in this aspect, which suitably amalgamated with a supportive therapy by the psychiatrist can cut the treatment period, bring an idealistic insight & bring the remission quickly, prevent relapse in future. Spirituality here means 'a divine sphere in owns inside that may be Called "Soul"; and unfolding an inside that you are not different or alone from the supreme'. 'I' and "thou" is inseparable, a part of universal divinity resolves their isolation and makes them relapse free.

Methods: In 150 patients attending Calcutta Pavlov Hospital comprising 3 groups of 50 each suffering from Anxiety Disorders, Anxiety depressive disorders (mixed), Dysthymia were included in a cluster. Each 25 patients of the 3 groups were given drugs only, and rest 25 of similar mach patients from 3 groups received both drug and weekly session on spiritualities applied application in own understanding. They were followed up each months interval for one year and then 3 monthly for another 2 years.

Results: Initial response were almost same in 2 g, on ongoing follow up both recovery and remising were high in spiritual touch up gr. Relapses were low.

Conclusion: Spirituality in therapy may help in recovery and well-being, in majority of psychiatric patients.

MODEL FOR EVALUATING THE LEVEL OF DEVELOPMENT OF COMMUNITY MENTAL HEALTH SERVICES

INSTITUTIONS
1. Faculty of Medicine. Universidad de Chile, Psychiatry and Mental Health. Campus Oriente, Santiago, Chile
2. Faculty of Medicine. Universidad de Los Andes, Psychiatry, Santiago, Chile

AUTHORS
1. Julia Acuña¹, Dr., MD, jacuna@med.uchile.cl
2. William Jadresin², Dr., MD, wjadresin@gmail.com
3. Cynthia Zavala³, Dr., MD, czaval@gmail.com
4. Alberto Botto⁴, Dr., MD, abottov@hotmail.com

Objective: To design a model for evaluating the degree of implementation of community mental health services in Chile.

Methods:
a) Stratified proportional multilevel sample, for 8 psychiatric units: 339 randomly selected patients, representative of all users(11020) of public mental health services of Chile
b) Construction of a development index of community psychiatry health services, based in three indicators: -Quality of structure -Level of development and functioning of community mental health net -Quality of process and flow of users
c) Design and application of Questionnaire and 30 day follow up in ambulatory health care system. d) Indicators are reduced to similar scale 0 (minimum) to 1 (maximum) to be able to compare them and to establish the final index.

Results: The structural quality was between 0.42 and 0.86; development and functioning was between 0.49 and 1 and process and flow between 0.35 and 1. Different units evaluated were arranged from higher to lower degree of development of community mental health services.

Discussion and conclusions: The article describe the implementation of a model for evaluating the degree of development of community mental health services. It was necessary first to establish a conceptual framework for defining fundamental dimensions that determine the model, then to develop a method for the evaluation. Theoretical and practical difficulties are discussed. Qualitative aspects, which could explain differences in level of development of community mental health services studied are discussed; some elements for improving the model are commented. Even this investigation shows the reality of Chile, the model could be adapted for being used in other countries.
At the last few years there is massive change in the ways of communication all over the world and this change led to a lot of similarities between originally different cultures. Globalization may be defined as a process in which the traditional boundaries separating individuals and societies gradually and increasingly recede. This shift of human affairs from the restricted frame of the nation-state to the vast theater of the world not only is affecting trade, finance, science, and the environment, it is also changing the nature of mental health challenges facing people all over the world. In this symposium the faculty will discuss the impact of globalization and changing culture on definition of mental health, mental health care system, diagnosis and management of psychiatric disorders and what we have to do to practice psychiatry in the shadow of these dynamic changes of culture.

AUTHORS
1. Paula Zimbrenan, MD, paula.zimbrenan@yale.edu
2. Gustavo Angarita-African, Dr., MD, gustavo.angarita@yale.edu

There is a high prevalence of psychiatric symptoms in patients with Systemic Lupus Erythematosus (SLE); however, information regarding their treatment is limited. Objectives: to describe the use and tolerability of psychotropic medications among patients with SLE treated in a primary care setting.

Methods: retrospective review of medical records. All patients fulfilled the Revised Criteria of the American College of Rheumatology and were prescribed psychotropic medications at some point during their illness. The following data was recorded: demographics, psychiatric diagnosis, presence or absence of neuropsychiatric lupus, prescribed psychotropic medications, duration of treatment, impact of treatment, adverse reactions, reason for discontinuation.

Results: among the 152 cases reviewed, the female/male ratio was 142/10, with African-Americans being the best represented group (37%). 44 (28%) patients received psychotropic medications. Selective Serotonin Reuptake Inhibitors were most commonly prescribed (20%). Twenty patients received more than one medication; six patients received three or more. No patient received maximum therapeutic dose despite reporting residual symptoms. Adverse reactions were common but moderate.

Conclusion: 28% of patients with SLE treated in a primary care setting are prescribed psychotropic medication, however their treatment is not optimized. Further research is needed to clarify if increased sensitivity to medications plays a role in the lack of treatment optimization.

ADVANTAGES OF THE AUTONOMOUS - SELF-RULING NETWORK OF COMMUNITY-BASED PSYCHIATRIC SERVICES COMPARED TO THEIR DEVELOPMENT RUN BY A PUBLIC GENERAL HOSPITAL

INSTITUTIONS
1. PSYCHIATRIC HOSPITAL OF PETRA OLYMPUS, COMMUNITY MENTAL HEALTH CENTRE, KATERINI, Greece

AUTHORS
1. Giorgos Angelidis¹, PSYCHIATRIST, Phd, info@kepsykat.gr
2. Nata Voura¹, PSYCHOLOGIST, aponota@hol.gr
3. Dimitris Xilas¹, PSYCHIATRIST, info@kepsykat.gr
4. Maria Tsarouha³, Mrs, info@kepsykat.gr
5. Constantinos Dimitriadis¹, Mr, info@kepsykat.gr

The psychiatric hospital of Petra Olympus (PHPO) is the first Greek psychiatric hospital that closed its chronic wards (2004). It has transformed into an autonomous Network of community-based psychiatric services in the Central-North Greece. Today, it is in liaison with the primary health care services in its catchment’s area and with medical services of the local public general hospital. The proposed policy changes in mental health care provision after the closure of public psychiatric hospitals in Greece with the administrative accession of the psychiatric services into the local general hospital will have a negative effect on the quality of the services provided to people with psychiatric problems in the catchment’s area. Psychiatric patients need services that offer integrated care, in the way it is provided by a therapeutic team. They strive for well organized services, and a network of services that assesses their individual needs and applies a holistic approach on their care. Usually, the general hospital approach of a psychiatric patient is emphasized on therapy but not on primary prevention of the mental health disease, sensitization of the general population, stigma, or family psycho education. The current Network of community-based psychiatric services of the PHPO, which can be extended in the future with new services, covers effectively many of the psychosocial needs of the population of its catchment’s area. We believe that there are important advantages in the function of this Network contrary to the development of psychiatric services administrative accessed in the local public general hospital.

4. Georgios D Giaglis¹, Dr, PhD, giaglis@med.auth.gr
5. Venetsanos Mavreas², Dr, PhD, vmavreas@cc.uoi.gr

Background: Estimating the satisfaction of psychiatric patients is considered to be one of the most important indications of quality of the psychiatric care provided.

Material and methods: In this survey, 168 psychotic psychiatric patients participated. Eighty-four of those resided in one of the Residential Care Facilities (RCF) of the Psychiatric Hospital of Petra Olympus, Greece, whereas 84 were clients of the Community Mental Health Center (CMHC) of Katerini. To estimate their satisfaction from the mental health services provided, the participants completed the Greek version of the Verona Service Satisfaction Scale-54 (VSSS-54). Their functioning (use of the Global Assessment / Functioning Scale - GAS/GAF), psychopathology (use of the Positive and Negative Syndrome Scale - PANSS), quality of life (use of the Quality of Life Scale - QLS), and their socio-demographic characteristics were also estimated.

Results: The total mean score of the VSSS-54 of the RCF residents was 4.12 ± 0.50 and of the CMHC clients was 4.34 ± 0.40 (p=0.002).

Conclusion: Both groups of patients recorded high percentages of satisfaction from the services provided. CMHC clients were more satisfied. Using multiple regression analysis it was found that 56.3% of the variability of RCF residents’ scores in VSSS-54 was interpreted by QLS, female gender, years of care by current psychiatric service, PANSS-negative (positive association), PANSS-total, GAS/GAF; and age (negative association), whereas, in CMHC clients, only a marginally significant 10.5% of the variability was interpreted, mostly through their education status and the diagnosis of schizophrenia.

THE ATTITUDES OF NURSES TOWARDS DEPRESSION AND DEPRESSIVE PATIENTS

INSTITUTIONS
1. Abant Izzet Baysal University, Izzet Baysal Medical School, Psychiatry, Bolu, Turkey
2. Dicle University Medical School, Psychiatry, Diyarbakir, Turkey

AUTHORS
1. Özden Arısoy¹, Dr., Assist. Prof., MD, ozdenariso@yahoo.com
2. Altan Essizoglu², Dr., MD, altanessizoglu@mynet.com

Aim: To determine and compare the attitudes of mental health nurses and general hospital nurses towards depression and depressive patients.

Method: 100 nurses, 70 of which working in a mental health hospital and 30 of which working in a general hospital for at least one year were interviewed. Questions about sociodemographic status and attitudes toward depression and depressive patients were asked by a questionnaire. Results were analyzed by chi-square test and t-test.

Results: The mean age, the total working time and ratio of married ones was higher in the mental health hospital nurse group. The general hospital nurses did not see depression as a disorder but rather regarded it as a condition everyone can fall from time to time and thought that depression was due to social problems whereas the mental hospital group saw depression as a mental disorder. Both groups had positive attitudes towards depressive patients. They stated that depressive patients could live in public and that they could work and get married with a depressive patient and that they could have a neighbour with depression.

Conclusion: The attitudes of nurses towards depression was much better compared to their attitudes towards schizophrenia which had been determined previously in the same group with another study. (1) This shows that different psychopathologies can cause different attitudes to develop in nurses.

4. Vesna Gerazova-Pejoska¹
5. Viktorija Vujovic¹

Goal: To present sociotherapeutic benefit for the social skills of the psychodrama techniques in patients with chronic psychiatric disorders.

Materials and Methods: 30 patients diagnosed with F20, F33 and F31 by ICD-X were treated in long term as outpatients as well as inpatients were involved in the research. At this time they are treated at the daycare hospital center with maintenance pharmacotherapy and once a week psychotherapeutic process (psychodrama). Patients were evaluated according to PANSS and scale for evaluation of the social skills. Evaluations were done at the beginning of the treatment, after 1 and 3 months.

Results: Patients that beside pharmacotherapy participated in the psychodrama had significant improvement in their social functioning regardless of the actual clinical condition.
It is postulated that prevalence of endogenous psychoses including schizophrenia is approximately similar in the world. On the territory of Siberia concomitantly 36 different peoples live, more than 300 ethnic communities with sparse composition in ethnic and cultural plan little brought together, but geopolitical positioning of subjects of this territory allows in known sense considering living here peoples as a uniform system of ethnic groups. Originating from priority assessment of full number of schizophrenic patients, we have identified a theoretic number of patients: in West Siberia, this magnitude has constituted near 315000, in East Siberia respectively - 174000 and in Far East - 146000, across Siberia as a whole this magnitude is near 635000. Real number of persons receiving treatment-counseling assistance and being under dispensary observation constitutes respectively 16.5%; 17.8% and 15.2% of therapeutic assessment. It is believed that only 20% of seeking for assistance at psycho-neurological dispensaries needs medical assistance and the rest needs social problems resolution, medico-social activities etc. If indicated corrections are accepted so currently specialized psychiatric assistance in Siberia and Far East is accessible to significant number of patients in need for it and does not depend on ethnocultural peculiarities of the population.

P-04-010

A CLINICAL STUDY OF CHILDREN AND ADOLESCENTS PRESENTING TO PSYCHIATRIC EMERGENCY SERVICES

Introduction: Over the past two decades there have been reports of increasing trend in children and adolescents presenting to psychiatric emergency services. Lack of access to community-based services is often hypothesized as the primary reason for this increase. There have been virtually no Indian studies on the clinical profile of these patients.

Objectives: To study the socio-demographic & clinical profile of children and adolescents presenting to psychiatric emergency services in a tertiary care general hospital setting.

Methodology: 42 children and adolescents presenting to psychiatric emergency services in a tertiary care general hospital setting were studied over a period of 22 months. A clinical interview was done with a structured proforma with the patients and attendants. Diagnosis was made on the basis of ICD-10 DCR. Rosenn’s classification was used to classify the presenting symptoms on the basis of acuity of problem.

Results: 85% of the sample was adolescents. 76% were females. The average number of cases was 1.9 patients per month. Majority of the patients presented with “pseudoemergencies” according to Rosenn’s classification. Dissociative/conversion spells were the most common presentation.

Conclusion: Pseudoemergencies constitute majority of children and adolescents presenting to psychiatric emergencies reflecting the lack of access to less urgent services in the community.

3. Dragutin Ivanec 3, divanec@ffzg.hr
4. Goran Tasic 1
5. Branimir Margetic 1

Aim: to assess internalized stigma and its relations to religiosity in a population of patients with schizophrenia.
Methods: Sixty seven patients with schizophrenia (59 men and 8 women) mean age 33,7 SD 9,5 years were included. Stigma was assessed with 29-item Internalized Stigma Mental Illness inventory (ISMI) that has five subscales: Alienation; Stereotype Endorsement; Perceived Discrimination; Social Withdrawal and Stigma Resistance, rated on four possibilities Likert scale: (1-strongly disagree to 4-strongly agree). Religiosity assessment included: general religiosity (1-not religious to 4-very religious), religious upbringing (yes/no), religious community support (1-no support to 4-very strong support), religious coping with the illness (1-very helpful to 3-not helpful at all).
Results: Age was significantly and positively correlated with ISMI (r=0,267), subscales Alienation (r=0,245) Stereotype Endorsement (r=0,368), and Social Withdrawal (r=0,284). Religiosity was not associated with ISMI or to any of its subscales, controlled for age. Religious upbringing was associated with subscale Perceived Discrimination (r=2,002; df=65; p=0,049). Those that had religious upbringing perceived more discrimination. Support of religious community was not associated with ISMI. Religious coping was associated with ISMI (F=3,41; df=2/63; p=0,039) controlled for age showing that those who stated that religiosity helped them partly, felt more stigma than other two groups (not helpful at all and very helpful).
Conclusion: in patients with schizophrenia internalized stigma is associated with some aspects of religiosity.

3. Medin Hodzic, Dr, esmina@bih.net.ba
4. Zihnet Selimbasic, Dr

Research conducted up to now point at connection of the lower monthly income with depression, anxiety disorders, and generally weak health condition. The aim of this research was to analyse the connection of psychological symptoms with monthly income of the employees in companies which were in process of privatisation.

Methods: In this research involved were 258 workers from seven companies which were in privatisation process from Tuzla Canton. Brief Symptom Inventory (BSI) was used for this research along with general questionnaire with sociodemographic data, and income and work place data. Data extracted were processed with descriptive statistics.

Results: The average age of analysed group of workers was 45.06±9.46 years, and average monthly income was 227.6±137.8 euros. The highest number of workers (80.2%) had under average monthly income in Federation of Bosnia and Herzegovina (309.33 euros). The workers with monthly income below average had on BSI scale increased somatisation, anxiety, paranoia, interpersonal sensibility, and hostility. The significant negative correlation between income rate, and expression of psychological symptoms on BSI scale was confirmed ($r = -0.184, P = 0.002$). The female workers with lower level of education, which were not married, and which were sub-tenants had lower income rate and more expressed psychological symptoms on BSI scale.

Conclusion: On the basis of the results it was found that social-economic factors such as monthly income, and the total family income, education level, marital status, and sex may be predictors for psychological distress.

The pillars of contemporary organizational approach of mental health were mental health centres which were linked to other services in the community into a unique network of mental health services. The aim of this research was to analyse psychiatric morbidity in outpatient care of mental health services during the period of one year.

Method: This research included analysis of psychiatric morbidity in three Mental Health Centres (CMHC) and one neuropsychiatry dispensary in the area of Tuzla Canton for 2007. The number of residents which these mental health centres covered with their service was: 52697 CMHC Gracanica, 51551 CMHC Lukavac and 45 000 CMHC Srebrenik, and 26000 were covered by neuropsychiatry dispensaries in Banovici. Data about mental disturbances, age and sex structure of patients were extracted from medical documentation.

Results: Significantly higher number of residents, older then 18, sought help in outpatient care services which cover the area with fewer number of residents ($p<0.05$). Concerning psychiatric morbidity, the lowest number of patients with schizophrenic disorder (3.7%) was in Gracanica CMHC, while the highest percent of such patients was in Lukavac CMHC (20.2%). The highest number of patients with depressive disorder was in CMHC Gracanica (41.7%), and the lowest in CMHC Srebrenik (15.7%). There was no significant difference between services in a number of patients with PTSD, anxiety disorder, and disorders related to addiction.

Conclusion: The most frequent mental disturbances in outpatient care settings were depression, anxiety disorder, and PTSD.

DISASTERS WORKERS, RELIGIOUS COPING AND EMOTIONAL INTELLIGENCE

INSTITUTIONS
1. Mazandaran Medical Sciences University, Sari, Iran (Islamic Republic of)

AUTHORS
1. Hamideh Azimi Lolaty¹, Dr, PhD, Hamidehazimi@yahoo.com
2. Shahrbano Ghahari¹, Mrs, PhD, Ghahari@yahoo.com
3. Abdolkarim Tigrari¹, Mr, PhD

Religious coping is expressed as benefit from religious beliefs and practices, for cope with problems and stressors in life. Emotional intelligence defined as the ability to perceive emotions, to access and generate emotions to assist thought, to understand and monitor emotions in themselves and other. As well as victims, disaster workers are also at increased risk of psychopathology. The aims of this descriptive study were to determine religious coping and levels of emotional intelligence, and its related factors. 187 Red Crescent volunteers (f =104, m=83 & mean=21.14 sd=3.36) from 13 city of Mazandaran convince were randomly selected. Bar-on MMEmotional Quotient inventory and Religious coping inventory were used. 44.9%, 5.3%, 5.3% and 7% of volunteers had adequate, under-developed, extremely under-developed and atypically impaired emotional capacity, respectively. Also, The Findings revealed 11.8%, 75.4% and 12.8% had high, moderate and low religious coping, respectively. Significant correlation found between religious coping and total Emotional Intelligence r=0.27 and 5 subscales of Emotional intelligence; Intrapersonal r=21%, Interpersonal r=41%, Adaptability r=23%, Stress Management r=26% and General mood r=27%. The implications of these findings are for using EI and religious coping as a predicator for vulnerability to traumatic stress among disaster workers.

INVESTIGATION OF MENTAL SYMPTOM LEVELS OF NURSES

INSTITUTIONS
1. Ege University School of Nursing, Department of Psychiatric Nursing, Izmir, Turkey

AUTHORS
1. Gönül Özgür¹, Dr., PhD, gonul.ozgur@ege.edu.tr
2. Aysun Babacan Gümüş¹, Dr., PhD, aysungumus@hotmail.com
3. Şifa Gürda¹, Mrs.

Objective: This study was designed to determine mental symptom levels of nurses and also to see whether background variables were related with their mental symptom levels.

Method: This descriptive study's sample consisted of 360 nurses who worked in one of the government hospitals in Turkish Republic of Northern Cyprus. Data were collected by using Nurses' Description Form and Symptom Check List-90-Revised (SCL-90-R) (1). As mentioned in the literature, over the 1.00 point of Global Symptom Index (GSI) mean score shows high level of mental symptoms (2). Data were evaluated using "t" test and ANOVA.

Results: GSI mean score of nurses were 1.11±0.66. The higher mean scores of the SCL-90-R subscales were found as following; obsessive-compulsive symptoms (1.21±0.73), somatization (1.20±0.64), paranoid thinking (1.17±0.80), hostility (1.14±0.82), interpersonal sensitivity (1.10±0.73). Nurses' sociodemographic findings as age, perceived economic status and nurses' working characteristics as department, number of nurse, ratio of patient, professional position, work year as a nurse, work hours per week, level of job satisfaction were found effective on GSI mean score.

Conclusion: It seems that nurses carry risk for their mental health and health care organizations.

MEDIA STAFF’S OPINIONS ABOUT MENTAL ILLNESSES IN TURKEY

INSTITUTIONS
1. Ege University School of Nursing, Psychiatric Nursing, IZMIR / BORNOVA, Turkey

AUTHORS
1. Leyla Baysan Arabaci1, Research Assistant, MD, baysanarabaci@hotmail.com
2. Şeyda Dülgerler1, Assistant Prof., PhD, seydanurmetin71@hotmail.com
3. Esra Bağ Enginy1, Assistant Prof., PhD, esrabasengin@hotmail.com

Background: It is known truth that the prejudices built up against the mental illnesses by the society effects the health staff’s treatment and care applications negatively.

Aims: This research was planned to investigate the media staff’s opinions about the mental illnesses.

Methods: The descriptive research was held by 73 people working in written and visual media from December 2007 - January 2008, in Izmir. Data were collected depending on individual announcement with 2 questionnaires forms after taking necessary permissions. The high point taken from Beliefs Toward Mental Illnesses Scale (BMI) shows the negative belief about the mental illnesses (Max:105).

Results: 63% of the participants are men, 52% of them are single and their mean age is 33.78±10.64. The media staff whose 46% works in editorial office and 34% works as correspondent work 61.50±20.84 hour in a week on an average. The BMI average point of the media staff is 52.30±18.17. In the study held by Çam and Bilge in Turkey, the BMI average point of the society was found as 59.98±16.17 (1);in another study held by Çam and Baysan-Arabaci, the BMI average point of the nursing students was found as 49.98±15.96(2).

Conclusion: It can be said that media staff have more positive beliefs about the mental illnesses in comparison with the society, but they have more negative beliefs in comparison with the nursing students that is a more professional group.

ACUTE INPATIENT CARE: RADICAL CHANGES, RADICAL RESULTS

INSTITUTIONS
1. Hellesdon Hospital, County Acute Service, Norwich, United Kingdom

AUTHORS
1. Julian Beezhold1, Dr, MBChB, MRCPsych, beezhold@doctors.org.uk
2. Pete Williams1, Mr, pete.williams@nwmhp.nhs.uk
3. Jenny Taylor1, Mrs, jenny.taylor@nwmhp.nhs.uk
4. Andy Harris1, Mr, andy.harris@nwmhp.nhs.uk

Aim: To assess the impact of radical changes to the way in which acute inpatient care is delivered to a population of 450000 in rural central Norfolk.

Method: In September 2006 a new system of acute inpatient care was introduced. This included a dedicated inpatient consultant psychiatrist, regular daily ward rounds, and enhanced roles for non-medical staff. A number of different outcomes measures were used to evaluate the effect the changes to the care system. These included length of stay, bed occupancy, violent incidents, absconsions, deliberate self harm incidents.

Results: Data was obtained on 2236 consecutive admissions from April 2002 - December 2007 of which 403 were admitted after the changes introduced in September 2006. These demonstrated dramatic impacts including 75% reduction in deliberate self harm, 50% reduction in bed occupancy, and over 50% reduction in violent incidents.

Conclusion: The impact of the service changes introduced was dramatic and has led to a sustained measurable improvement in both ward environment and outcomes. This has direct benefits to patients, staff and has also reduced costs.

MAKSHIVIM - AN INTERACTIVE ONLINE PROJECT TO PROMOTE RECOVERY & SOCIAL INCLUSION OF PERSONS WITH PSYCHIATRIC DISABILITIES

INSTITUTIONS
1. Makshivim, Tel-Aviv, Israel

AUTHORS
1. Eitan Ben-Itzhak Klutch1, Mr., MA, eitan@makshivim.com
2. Daniel Cochavy1, Mr, danielcochavy@yahoo.co.uk

Makshivim is an Internet-based project for people with psychiatric disabilities. Through the project, participants chat with each other and/or with a professional guide to achieve one or more of the following goals: To raise awareness of mental illness and ease societal and self-stigma; To practice social and communication skills; To find friends from the consumers population with common experiences and interests; To organize courses of study; To find rehabilitative jobs and jobs in the wider community. The program’s moderator online guides are consumers themselves and serve as instructors for courses set up by the program.

Rationale
People with psychiatric disabilities deal with a range of difficulties, including public, institutional, and self-stigma, difficulty adhering to formal, community-based rehabilitation services, and high unemployment. This may lead to social isolation and loneliness. In Makshivim the consumers can build social ties with peers, while still maintaining anonymity.

Uniqueness
This is the only project of its kind that makes rehabilitation through the internet, and after 2 years of operation and one year formally, it has already proven that consumers - who want to live in a maximally normative way - need a forum for free and independent interaction without confining themselves to the mentally ill community.

Summary
This is an internet social-rehabilitative project, which serves a population that experiences pervasive social isolation.

CHARACTERISTICS OF HIV+ PATIENTS TREATED IN A PSYCHIATRIC EMERGENCY DEPARTMENT

INSTITUTIONS
1. University of Washington, Psychiatry, Seattle, United States

AUTHORS
1. W. R. Murray Bennett1, Dr., MD, FRCP, mbennett@u.washington.edu
2. Jutta M Joesch1, Dr., PhD, jjoesch@u.washington.edu
3. Michelle A Mazur1, Dr, PhD, mamazur@u.washington.edu

Purpose: Knowledge about the characteristics of patients using psychiatric emergency services is expanding. However, to date the prevalence of HIV infection among patients treated at psychiatric emergency departments is not known, and neither are the characteristics of HIV+ patients seen in this setting. Thus, the aims of this study are: (1) to estimate the prevalence of HIV infection among patients utilizing psychiatric emergency services in a large, urban, level 1 trauma center; and (2) to describe demographic and clinical characteristics of HIV+ versus HIV- patients in such a setting.

Methodology: Data were collected over a ten-year period for patients who had visited a large, inner city psychiatric emergency department. Information on HIV infection and demographic and clinical characteristics was obtained from the medical record. To accurately present the prevalence of HIV infection among patients treated at the Psychiatric Emergency Department, we calculated the infection prevalence, as well as the clinical and demographic characteristics, per visit.

Results: Almost 2% (1.8%) of Psychiatric Emergency Department Visits were by HIV infected patients. HIV infected patients were more likely to be male, African-American or race other than Caucasian, African-American, Asian-American or Native-American, and homeless. These patients were also more likely to be Demented, Suicidal, Abusing Substances, or coping with Borderline Personality Disorder.

Conclusion: These findings have wide public health implications in considering both the increased needs of this patient population and utilization of psychiatric emergency services.

SOCIAL SERVICES FOR PSYCHIATRIC CLIENTS: WHAT CAN PILSEN MUNICIPAL AREA OFFER?

INSTITUTIONS
1. Charles University Prague, Medical Faculty Pilsen, Psychiatry, Pilsen, Czech Republic
2. Obcanske sdruzeni Ledovec, Ledce, Czech Republic

AUTHORS
1. Jiri Beran1, Mr., MD, beran@fnplzen.cz
2. Martin Fojticcek2, Mr., ledce@volny.cz
3. Jiri Podlipny1, Mr., MD, podlipny@fnplzen.cz

The aim of the lecture/presentation is to inform about the social services for psychiatric clients in the municipal area of the City of Pilsen. This municipal area has about 200,000 inhabitants. During the last 10-15 years, considerable development of social services for psychiatric clients has been put into life. These social services are independent on the psychiatric health care system which takes care of in- and outpatients. A lot of non-profit organisations care about psychiatric patients with the aim to integrate them into the society. The integration has several aspects such as interpersonal relationships, social life, working skills, culture and hobbies. These organisations offer a broad spectrum of activities e.g. sheltered workshops, educational courses, cultural programmes, meals and housing. They cooperate with health care organizations, educational or religious institutions and voluntary organizations. They get their financial support from local resources and the European Union. By raw estimation these organisations in Pilsen municipal area offer services to 250 clients.

TIME OF DAY AT REFERRAL TO ACUTE CARE AND DIAGNOSIS

INSTITUTIONS
1. Lovisenberg diakonal hospital, Department of psychiatry, Oslo, Norway

AUTHORS
1. John e. Berg1, Dr, MD PhD, john.berg@lds.no

Introduction: Patients are referred to acute psychiatric care at all times during the day, and a substantial part are referred outside office hours. This applies to both compulsory referrals and referrals at the free will of the patient. There is a scarcity of research into this time related area. The diagnoses of patients referred may influence when patients are referred. Method and material: A one year cohort of patients referred to the acute care unit was investigated using the hospital computerized register, which contains socio-demographic and clinical information plus information on the exact time of referral. Results: 1323 patients were referred, slightly more women than men, the age distribution was from 18 to 88 years. 52% arrived within office hours, 39% in the afternoon and early night and 9% later at night. 19% of the resident stays ended within 24 hours. Further results will be presented as a poster in Prague in September 2008.

Large areas in the Peloponnese were devastated by wildfires in August 2007. Firefighters were on duty for several days without sufficient rest. Due to this disastrous event 3 firefighters and 40 other people were killed. One month later, a group of mental health clinicians from the University Mental Health Research Institute (UMHRI) and the 1st Department of Psychiatry of the University of Athens visited the disaster area in order both to provide psychological support and to investigate the psychosocial consequences of this catastrophic event. 102 firefighters were interviewed using several questionnaires, among them Eysenck’s Personality Inventory1 and the Albert Einstein College of Medicine Copying Styles Questionnaire (AECOM - CSQ)2. 18.6% of the firefighters who took part in the operation were found to have PTSD according to ICD-10 criteria. Logistic regression showed that seasonally employed firefighters who presented with higher neurotic personality features and used the mechanism of minimization to a greater degree were more likely to develop early PTSD. It seems that coping mechanisms might influence the development of post-traumatic stress symptoms.

MULTIPLE MEDIA ADDICTION- AN EMERGING PROBLEM IN DEVELOPMENTAL PSYCHIATRY

INSTITUTIONS
1. Vivantes Netzwerk Berlin, Kliniken für Kinder- und Jugendpsychiatrie, Germany

AUTHORS
1. Oliver Bilke1

Introduction: The Internet, modern electronic media and online gambling have changed adolescent socialisation in the last decade. Although some researchers still do not see this social and technological problem as an aspect of dependency, there is a need for clinical useful classification and diagnostic criteria.

Method: Research on published classification systems such as ICD-10, DSM-IV, on medical and psychological databases and single publications on the topic from 2000-2007.

Results: There is no consistent possibility to diagnose or classify a distinctive subgroup of patients with severe dependency problems concerning the electronic media. DSM-IV and ICD-10 provide the well known categories of impulse control disorders, gambling or dissocial behaviour only covering a part of the individual problems. There is only one useful published classification not researched upon yet.

Conclusion: With the increasing impact of electronic media even on children, there is a need of specialised developmental oriented classification systems to distinguish clearly between phasic behaviour patterns in adolescents and different severe disease processes maybe summarized as multiple media addiction (MMA) .

GENEVA’S INTERNATIONAL ORGANIZATIONS HEADQUARTERS: DO THEY ATTRACT TRAVELERS IN NEED OF MENTAL HEALTH CARE?

INSTITUTIONS
1. Geneva University Hospitals, Psychiatry, Geneva, Switzerland

AUTHORS
1. Ariel Eytan¹, Dr.
2. Laurence Borras¹, Dr.

Objectives: Several international organizations have headquarters in Geneva and are thus hypothesized to attract both people seeking help for human right abuses and pathological travelers. A previous study showed that the latter category, albeit small, represent an identifiable cause of psychiatric hospitalizations in the local public psychiatric hospital (1). The present survey aimed at examining this question from the Organizations' perspective rather than from the hospital's point of view.

Methods: Medical, administrative and security officers belonging to 17 different Organizations were interviewed by one of the authors. Questions covered a one-year period (September 2005 to September 2006).

Results: Over a one-year period, 297 visits considered as inappropriate were recorded. Visitors were in majority male (60%), aged above 40 years (80%) and lived alone (90%). Twenty percent came from Switzerland, 40% from European countries and 40% from other areas of the globe. Psychotic symptoms, mainly delusions of persecution, grandiosity and ideas of influence, seemed to underlie almost 90% of these visits. The international vocation of Geneva was invoked as a reason for choosing this destination.

Conclusions: It is important to distinguish people seeking help for human right abuses from pathological travelers, since responses should of course be different. However, both categories of visitors can represent a non-negligible work load for international Organizations' medical services.

ANALYSIS OF THE PROFILE OF PATIENTS SUBMITTED TO BARIATRIC SURGERY IN THE SURGERY WARD OF THE SANTA CASA DE SÃO PAULO

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbluscato@uol.com.br
2. Luciana Rodrigues Theodoro¹, Mrs., MS, chpsicol@santacasasp.org.br
3. Carlos Alberto Malheiros¹, Mr, MD, chpsicol@santacasasp.org.br

Introduction: Surgery is the elected treatment for patients with a body mass index equal to or over 35, because only 1% of these patients can lose weight through conventional treatments. In the long run, the success of the surgical treatment does not depend on the procedure, but on the patient’s adaptive capacity.

Aim: To analyze the profile of patients who have had surgery at the Santa Casa de São Paulo.

Method: Analysis of the following variables: gender, age, schooling, body mass index, pre-surgery weight variation and associated diseases in 265 patients both male and female who have undergone Capella type Gastroplastic surgery between 1999 and 2004 who are now in multidisciplinary monitoring in this institution. Results: 13,6% were male and 86,4% female. As for age, 20,5% were between the ages of 20 and 29 years, 37,3% between 30 and 39, 29,4% between 40 and 49, and 13,7% were above 50 years. Regarding schooling, 36,2% had completed middle school, 29,4% had completed high school and 14,3% had completed university. The body mass index varied between 35-39 (10,1%), 40-44 (24,5%), 45-49 (24,9%), 50-54 (18,4%), 55-59 (10,9%), 60-64 (5,6%), 65-69 (5,2%), over 70 (0,3%). The pre-surgery weight variation consisted on the greatest weight equal to 220 Kg and smallest weight equal to 84 kg. 56,7% of the sample did not present associated diseases.

Conclusions: Mostly women, with ages between 30 and 50 years and schooling with middle school complete; with a body mass index between 40-50 and with no associated diseases.

COPING STRATEGIES USED BY NEPHROPATHIC AND HEPATOPATHIC CANDIDATES TO TRANSPLANT

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Paula Silva Kioroglo¹, Ms., chpsicol@santacasasp.org.br
3. Rosana Trindade Rodrigues¹, Mrs., MS, chpsicol@santacasasp.org.br

Introduction: Nephropathic and hepatopathic candidates to transplant present physical and psychosocial difficulties and need coping mechanisms that can guarantee the treatment's success and reduction of the emotional strain.

Aim: To describe the coping strategies used by the nephropathic and hepatopathic patients being evaluated for transplant.

Method: 9 nephropathic patients, 4 female and 5 male, with an average age of 51 years; and 9 hepatopathic patients, 1 being female and 8 male, with an average age of 54 years, all in pre-transplant evaluation, answered to the Ways of Coping with Problems Scale (E MEP).

Results: The coping strategies focused on the problem that use behavior directed to handling and solving related to treatment as well as re-meaning of the disease were used by 22% of the nephropathic patients and 44.5% of the hepatopathic patients. The strategies focused on the emotion that are related to blaming others or self-blaming, moving away from the problem or expression of negative emotions were not used by any of the two groups. The strategies focused on the search for religion/imaginative thoughts were used by 45% of the nephropathic patients and 44.5% of the hepatopathic patients. Finally, the strategies focused on the search for social support that can be defined by the search of a social and family net to deal with the disease and treatment was used by 33% of the nephropathic patients and 11% of the hepatopathic patients.

Conclusion: The groups present different strategies to deal with the disease, treatment and search for transplant.

CORRELATION BETWEEN PHYSICAL IMAGE AND SOCIAL SKILLS IN WOMEN WHO ARE AWAITING BARIATRIC SURGERY

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Luciana R. Theodoro¹, Mrs., MS, chpsicol@santacasasp.org.br
3. Carmen N. Benedetti¹, Mrs., PhD, chpsicol@santacasasp.org.br
4. Carlos A. Malheiros¹, Mr., MD, chpsicol@santacasasp.org.br

Introduction: Obesity is a chronic disease of multifactorial etiology. The interference of psychological factors can also be observed, especially those related to a negative physical image, which can cause as consequences: feeling of inadequacy as a human being, inadequacy in a few social interactions and low self-esteem.

Aim: To evaluate the Physical Image and the possible inter-relation of it with these patients' social skills.

Method: 20 female patients with an average age of 40.65 years, were evaluated with the Physical Image Questionnaire - Version for Women (BSQ) and with the Social Discomfort and Aloeofness Scale (SAD). These patients presented an average weight of 122.45 kg and a body mass index average of 47.803 kg./m.

Results: Of the 20 patients who took part in the research, 95% demonstrated a change in Physical Image, 10% of those with a small alteration, 30% with a moderate alteration and 35% serious alteration. Regarding the Social Skills, 60% of the patients presented a good ability for them and 40% presented low ability in the social skills, however, the correlation between Physical Image and Social Skills was not significant.

Conclusions: Most of the patients presented a different Physical Image and all those who presented difficulties in social interactions demonstrated a serious alteration in physical image. This data suggests that the manner in which these patients interact in the social environment does not only depend on the quality of their physical image, but also on internal aspects of their personality.

EMOTIONAL ASPECTS INVOLVED IN THE TREATMENT OF BOTOX APPLICATION IN HEMIPLEGIC PATIENTS CAUSED BY CEREBROVASCULAR ACCIDENT (STROKE).

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbbruscato@uol.com.br
2. Valéria Wojciechowski¹, Mrs, MS, chpsicol@santacasasp.org.br
3. Sérgio Lianza¹, Mr., MD, chpsicol@santacasasp.org.br

Introduction: After a cerebrovascular accident, the patients present various adjustment difficulties, including the non acceptance of physical limitations and incapacities. The visibility of physical difficulty is one of the main conflicts, leading to a social isolation and personal devaluation. Hence, the will to solve these frustrations trough treatments is constant.

Aim: To evaluate the level of expectancy facing the treatment proposed by the Concentrated Espasticity Assistance done by the Rehabilitation staff of the Santa Casa de São Paulo.

Method: Semi directed interviews with 19 patients before and after the application of chemical neurolysis (botox) were carried out, where the patient was allowed to talk about feelings and thoughts regarding treatment.

Results: The results pointed to the need to evaluate the level of expectancy towards this treatment, seeing that all the patients presented idealized expectations, which can create feelings and behavior that can compromise the results, such as non adherence to treatment and, in future, intense frustration levels. The presence of anxiety and depression symptoms shown by the patients expresses the difficulties in accepting physical limitations.

Conclusion: The need for psychological monitoring during the process was verified, so that these expectancies may be made adequate, allowing the individual to deal with treatment and its results in a realistic manner.

P-04-030
EVALUATION OF THE DEGREE OF SATISFACTION OF THE PRE-SURGERY EXPECTATIONS IN PATIENTS SUBMITTED TO THE OBESITY SURGERY

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbbruscato@uol.com.br
2. Luciana R. Theodoro¹, Mrs., Ms, chpsicol@santacasasp.org.br
3. Luzia D. Santos¹, Mrs., chpsicol@santacasasp.org.br
4. Carmen N. Benedetti¹, Mrs., PhD, chpsicol@santacasasp.org.br
5. Carlos A. Malheiros¹, Mr., MD, chpsicol@santacasasp.org.br

Introduction: Thanks to the great difficulty that this patient has in losing weight and maintaining it after achieving the ideal weight, it is expected that the obesity surgery (as a promise of slimming guarantee) awakens high expectations in the obese person. These not always realistic expectations may not be met in the post-operative period.

Aim: To assess the degree of satisfaction of expectations regarding the results of weight loss in morbid obese patients submitted to the obesity surgery.

Method: 40 patients who underwent the obesity surgery were evaluated and monitored for at least one year, with ages between 25 and 67 years, 34 female and 06 male. The protocol for the routine evaluation of this institution’s psychological consultation was used for this study. The variables analyzed were the expectations regarding professional life, appearance and aesthetics, emotional, social and family relationships, health and leisure.

Results: The expectations were prioritized in the following order: 1st Health, 2nd Appearance and Aesthetics, 3rd Professional Life and Emotional Relationships, 4th Social Relationship, 5th Family Relationship and 6th Leisure. As need for improvement in order of priority, the following were mentioned: Health with 55%, Appearance and Aesthetics 17.5%, Professional Life with 17.5% and Emotional Relationships with 10%. The other variables (social relationship, family and leisure) were seen as a need for secondary improvement, and it was also reported that these variables were significantly dependent on improvement of the first.

Conclusion: The expectations expressed were significantly achieved by patients submitted to the obesity surgery.

CHARACTERIZATION OF THE CONSULTATIONS CARRIED OUT BY THE TEENAGER AND CHILDREN’S PSYCHOLOGY IN THE PRIMARY HEALTH ATTENTION

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Roberta Maia Sessa¹, Mrs., chpsicol@santacasasp.org.br
3. Flávia Fusco Barbour¹, Mrs., chpsicol@santacasasp.org.br

Introduction: The Barra Funda School Health Center has to promote health according to prevention precepts as its aim. However, we noticed that the demands of this equipment are adverse to the Primary Attention proposal. Aim: To characterize the population and demand of the use of the Health Center for thought and comparison with other equipment, aiming towards the creation of more efficient proposals.
Method: To go through 68 files of patients with ages between 03 and 17 years who went through teenager and children’s psychological triage from August 2006 until February 2007.
Results: 28% of those who use the service are between the ages of 03 and 06 years; 34% between 07 and 10 years and 38% between 11 and 17 years, 72% of them male and 28% female. The study showed that 44% of the patients come to the Psychology Service with a specific school complaint; 22% with a family demand; 20% with various complaints; 13% with organic complaints and 1% with a complaint of violence. In other words, a significant number of children and teenagers come directed by the school seeking a psychological evaluation for learning and behavior disorders, especially hyperactivity.
Conclusions: The highest percentage of complaints regards school problems, which suggests the need for a new investigation about educational, social and family matters. We noticed the importance of psychoprophilactic interventions in the family circle, seeking to avoid that a great number of emotional factors significantly harm the teenagers’ and children’s learning process.

P-04-032
CHARACTERIZATION OF THE INTER-CONSULTATION REQUESTS BY THE ADULT PSYCHOLOGICAL CONSULTANCY SECTOR OF THE SANTA CASA DE SÃO PAULO

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs, PhD, wlbruscato@uol.com.br
2. Marcela Mayumi Kitayama¹, Mrs, chpsicol@santacasasp.org.br

Introduction: The Psychological Consultancy in the General Hospital is an important intervention model in the health area. Professionals from various specialties may request a psychologist’s opinion when they identify emotional problems interfering in the treatment of the hospitalized patient.
Aims: To characterize the psychological inter-consultation requests received by the Adult Psychological Consultancy Sector between 2002 and 2006, comparing them throughout time.
Method: 715 consultation requests regarding adult patients. The data was obtained retrospectively in register protocols of the consultation requests, in institutional reports and previous studies. The following were investigated: origin of the request, category of the requesting professional, reason for request, patient’s gender and age.
Results: The consultation requests were made by doctors (82,8%), and mostly came from the Medical and Orthopedic Clinics (44,76%), followed by the Surgery and Psychiatry Clinics (23,50%). There was a greater frequency of patients between the ages of 15 and 35 years (42,42%), 55,94% female. Depression (27,55%) and unadjusted behavior in the emotional point of view were amongst the most frequent reasons for a request for psychological evaluation.
Conclusion: The frequency of depression and suggestive behavior of adjustment disturbance was high. The systematic register adopted as practice allows the evaluation and follow-up of the relationship with the service users. The constant demand suggests that the Psychological Consultancy Sector is an assisting resource for the institutional specialties and an important aspect in the construction of complete care in the health area.

IMPLANTATION AND CHARACTERIZATION OF A PSYCHOLOGY SERVICE IN THE GENERAL HOSPITAL

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato1, Mrs., PhD, wlbruscato@uol.com.br
2. Maria das Graças S. Lima1, Ms., Ms, chpsicol@santacasasp.org.br

Introduction: The implantation of a Psychology Service in a General Hospital with 180 beds implicates in a systematization of acting in the institution as a whole, seeking multidisciplinary interaction and identification of demands. Hence, the Interconsultation Model has proven itself adequate.

Aim: To characterize the interconsultation requests received by the Psychology Service during the implantation in a General Hospital, from April/2006 to May/2007. To identify the requests’ main demands and applicants.

Method: 52 consultation requests regarding hospitalized patients. The data was obtained retrospectively in registration protocols of the consultation requests, as well as from institutional reports. The following were investigated: gender, age, social status and patient’s diagnosis, psychological demand observed and requesting staff.

Results: A total of 52 evaluation requests, 77% being adult patients. 75% female with diagnosis of: adjustment disturbance (50%), depressive state (32%), suicide attempt (15%) and difficulty to adhere to treatment (3%). Male (25%), with a diagnosis of: difficulty to adhere to treatment (65%), adjustment disturbance (30%) and anxiety disturbance (5%). Regarding the Pediatric patients (23% of the total), the following cases prevailed: domestic violence (50%), adjustment reactions (35%) and parent orientation (15%). The main requestants were: Medical Clinic (46%), Pediatrics (23%), Social Service (20%) and Gynecology/Obstetrics (11%).

Conclusion: The Interconsultation model allows the identification of demands and the insertion in the multidisciplinary staff, favoring the creation of strategies to optimize the assistance during the implantation of the Psychology Service.

INFLUENCE OF PHYSICAL IMAGE IN THE EVERYDAY LIFE OF LARYNGECTOMEE PATIENTS IN THE FIRST POST-SURGERY YEAR

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato1, Mrs., PhD, wlbruscato@uol.com.br
2. Daniela Achette1, Mrs., chpsicol@santacasasp.org.br
3. Antonio José Gonçalves1, Mrs., MD, chpsicol@santacasasp.org.br

Introduction: Studies point out that as time goes by, the laryngectomee recreates his/her ideals of physical image, confronted by the real condition of being aphonie, or presenting a tracheotomy. Others suggest that there is no adjustment but a passiveness regarding the condition. There are losses in roles and the body’s ideal image, but, to have survived such a stigmatized disease as is cancer is an extremely valued point.

Aim: to identify the influence of physical image in the everyday life of complete laryngectomies (LT) in the first post-surgery year.

Method: Prospective descriptive transversal study, with a laryngectomee with at least six months and maximum one year of post-surgery. We used a protocol created for this finality and the drawing of the human figure (Buck, 2003).

Results: We evaluated 10 patients, all male. The age group varied between 40 and 75 years. Regarding the professional impact, 40% retired after the complete laryngectomy and 60% presented a loss in social relations compared to before the sickness, however, they referred that they accepted the new condition and were glad to be alive. The main complaint was regarding communication, 70% mentioned difficulty in more refined contact in the psychosocial relation and 80% presented good adjustment to physical image (including dealing with tracheotomy).

Conclusion: There was an impact especially in communication, causing a certain psychosocial damage. However, the patients developed a good adjustment regarding physical image in the late post-surgery.

INTERDISCIPLINARY TRIAGE MODEL IN PRIMARY HEALTH ATTENTION

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Flávia Fusco Barbou², Ms., chpsicol@santacasasp.org.br
3. Roberta Maia Sessa¹, Ms., chpsicol@santacasasp.org.br

Introduction: This proposal presents groups of triage in mental health (Psychology and Psychiatry) with the participation of the Social Service.

Aim: To optimize the welcoming time of new cases for the mental health Service. With this model, we expect a greater organization in conduct, making the monitoring and/or forwarding of cases easier.

Method: The triage was interdisciplinary, relying on a psychologist, psychiatrist and social worker, and was done once a week at different times, in group, with an established number of six vacancies per time. The patients, 47 of them, were seen in group at the first moment and after the complaints were sorted and the professionals discussed among themselves which would be the most appropriate conduct for each patient and the feedback was given individually.

The participants would leave with their specialty consultation already done and/or forwarded/scheduled to the specific place.

Results: In a sample of 47 patients, 11 left the triage with two or more indications for the psychology, psychiatry and social service specialties, which meant 23.4% of the cases. The adoption of this model also brought an optimization of the patient’s time in the Service.

Conclusion: Diagnoses and indications to specialists took place in a more adequate and objective manner. We thus had a more organized movement of these users and guaranteed a greater assertivity of the Service. This shows the importance of joined practice by health teams, taking the population’s demand into account.

MULTIDISCIPLINARY GROUP WITH FAMILIES OF PATIENTS ADMITTED IN THE ADULT INTENSIVE CARE UNIT

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Luciana C. Sasso², Mrs., chpsicol@santacasasp.org.br

Introduction: The Intensive Care Unit is a clinic destined to care for patients with serious illnesses and who need intensive care. The death stigma is extremely present in this context, due to the patients’ serious clinical state. The setting of the Intensive Care Unit is a triggering factor for psychopathological changes in the patient, family and members of the staff, causing depression, anxiety and fear. For the family, the diagnosis of a serious disease is, many times, a factor of intense psychological breakdown, making it clear that the family needs a differentiated look from the health team. Hence, the interdisciplinary action provides benefits to all the involved parts, seeing that the feeling of shelter, trust and security manifest themselves in both the family and the patient, improving their relation with the disease process, hospitalization and treatment.

Aim: To evaluate the effect of the multidisciplinary group with families of patients admitted in the ICU, looking at their own level of anxiety.

Method: Application of the Beck Anxiety Inventory (BAI).

Results: 76% of the family members demonstrated greater confidence in the staff and greater comprehension of the patient’s general condition and the need for the stay in the Intensive Care Unit, minimizing the degree of anxiety after coming to the group.

Conclusion: Feelings of anxiety and anguish when facing the situation of admission in the ICU were minimized by group intervention. Besides this, there was an improvement in the relation and communication between family members and staff.

OBESITY AND DOWN’S SYNDROME

INSTITUTIONS

1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS

1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Luciana Rodrigues Theodoro¹, Mrs., MS, chpsicol@santacasasp.org.br

The obesity comes increasing too much in the last few decades however, the epidemic still little is studied in people with Down’s syndrome, whose situation propitiates a bigger development of the illness. Objective: to identify the existence of overweight and obesity in adolescents with Down’s syndrome and establish relations with eating habits, hormonal alterations, practices of physical activities and emotional behavior. Had participated in this study 40 adolescents with Down’s syndrome between 10 and 19 years of both sex and their respective mothers. Results: In relation to the weight, 20% with overweight and 40% with obesity. The eating habits had demonstrated that 40% eat more than the majority of the people, in the opinion of their mothers. The compulsory search for foods was related by 65% of the interview. The overweight and the obesity had been took of alterations of thyroid in 50% of the cases, of cardiopaties in 57.5%, familiar historic of obesity of 27.5% in fathers and 31% in the mothers and the practical of physical activity in 62.5%. The mothers had chosen as predispositions factors of the overweight and obesity in their children the fact to have Down’s syndrome and the adolescents demonstrated to have idea of what it is necessary to make to lose weight and make distinction between healthful and not healthful foods. Conclusions: the combination of diverse factors can interfere with the presence of the excess of weight in the population with Down’s syndrome.

PSYCHOLOGICAL ASPECTS FACING DIAGNOSIS AND HOSPITALIZATION OF HIGH-RISK PREGNANT WOMEN

INSTITUTIONS

1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS

1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Adriana A. Fregonese¹, Ms., MS, chpsicol@santacasasp.org.br
3. Roberta M. Sessa¹, Ms., MS, chpsicol@santacasasp.org.br

Introduction: Many physical and emotional changes take place during pregnancy accompanied by anxieties, fears and fantasies, but it is in a high-risk pregnancy that they become aggravated. High-risk is defined by everything that exposes the pregnant woman and the conception to physical, psychological and social aggravations. The woman may present difficulty of emotional adjustment, and feelings of guilt and helplessness are frequent.

Objectives: This study had as its objective to identify the emotional reactions facing the diagnosis and hospitalization of high-risk pregnancies.

Results: 86 psychological attendances were held. Regarding diagnosis, 34% of the patients reported feelings of anxiety, surprise, fright and fear; 27% reported feelings of abandonment and helplessness facing sickness; 24% expected the diagnosis because of previous pregnancies, but with negative feelings and 15% failed to express in words which were the feelings triggered. Regarding admission to the hospital, it was found that 64% reported negative feelings (anguish, anxiety, fear and sadness), and 36% described the hospital with positive feelings (refuge, protection and care).

Conclusion: We noticed that the diagnosis of a high-risk pregnancy can lead to a disorganization of thought and feelings and pregnant women show themselves lost and disoriented, intensifying defense mechanisms such as denial, rationalization and regression. As for the admission, we noticed the presence of negative feelings, often projected towards the institution and the staff, as something threatening to the continuity of gestation. The psychological monitoring and integrated assistance can help in the psychological reorganization and re-signification of the pregnancy.

PSYCHOLOGICAL ASSISTANCE IN OBSTETRICAL WARD WITH PATIENTS IN PREMATURE CHILDBIRTH

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Adriana A. Fregonese¹, Ms., MS, chpsicol@santacasasp.org.br
3. Roberta M. Sessa¹, Ms., MS, chpsicol@santacasasp.org.br

For mothers of babies born prematurely, the puerperium tends to be seen as a time of acute crisis, anxiety and stress, with many questions and feelings that trigger intense feelings of depressive guilt. The difference between the real and imaginary baby is quite pronounced.

Objective: to create a space for the expression of the pregnant women’s subjectivity, an area in which feelings, emotions and reactions facing premature childbirth were accepted, for discussion and comparison of the real premature baby and full term baby.

Method: This study was conducted in an obstetrical clinic ward through individual psychological consultations with 14 patients. The verbal expression of feelings related to pregnancy, with the future baby, love life with companion and family were stimulated.

Results: The psychological assistance provided emotional support to the mothers facing the imminence of premature birth. We noticed the restructuring process of the pregnant women and the putting off of the moment of birth. 11 patients managed to take the pregnancy to the gestational age deemed appropriate. only 3 patients gave birth in advance and demonstrated a high degree of anxiety in the puerperium.

Conclusions: The psychological assistance in the ward shows itself effective in the moment of intense anguishes and anxieties facing childbirth, helping in the pregnant woman’s psychological reorganization. The importance of psychoprophilactic intervention can be seen in the pregnant puerperal cycle, avoiding many factors to configure in the pre-term birth.

RESIDENT DOCTOR’S EMOTIONAL REACTIONS TOWARDS A PATIENT IN PALLIATIVE TREATMENT

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Daniela Achette², Mrs., chpsicol@santacasasp.org.br

Theme of death and such a theme frequently generates feelings of omnipotence in the doctor.

Aim: To identify which are the resident doctor’s main emotional reactions and attitudes towards terminal patients.

Method: This study had residents of General Surgery as participants. A standardized questionnaire created by the researcher was used. The format of the study was descriptive transversal.

Results: 28 questionnaires were distributed and out of these, 13 were answered. 69% of the researches talked about the prognosis with patients, but 91% of these make use of help from the family members. The main feelings experienced by the residents are impotence and sadness (23% each), indicating that, for them, death represents failure. In cases where patients or family members ask the resident for a procedure to cure the disease, we noted feelings of impotence (18%), anguish (22%) and pity (22%), due to difficulty when dealing with the situation. Most of the residents (73%) answered that they would tell the patients in palliative treatments who asked about their prognosis the truth. They affirm that the patient knowing or not depends mainly on each one’s structure of personality (31%) and the importance of their preservation of independence (49%). The main requirement, according to the residents, is the cultivation of the doctor-patient relationship, necessary when dealing with patients (39%).

Conclusions: The study indicates difficulty in most of the participants in dealing with the theme and communication of death to their patients, family members and themselves.

THE INFLUENCE OF MOURNING IN THE ORGAN AND TISSUE DONATION PROCESS

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Paula Silva Kioroglo¹, Ms., chpsicol@santacasasp.org.br
3. Rosana Trindade Rodrigues¹, Mrs., MS, chpsicol@santacasasp.org.br
4. Yvothy A. Sens¹, Mrs., MD, chpsicol@santacasasp.org.br

The need of family consent for donation in a delicate moment places mourning as one of the intervening factors of this process.

**Method:**
Bibliographic survey about the themes: organ donation, mourning, family.

**Results:**
Donation can have different meanings for family members: comfort, satisfaction, honor, pain, among others and is inevitably associated to mourning. Therefore, it can represent an increase in stress for the family members, but may also mean comfort. According to literature, families of donors have an inadequate comprehension about the definition of brain death, so the institution's support throughout the process is necessary, giving them information and opportunities to visit the donor, before and after donation. To monitor family members offering emotional support from the moment of diagnosis and after, when consent for donation has been given, prevents the mourning process to negatively influence the donation and later, on the experience of becoming a donor.

**Conclusion:**
It can be seen that the increase in donors depends on a look that goes further than the technical issues of the organ donation process, taking into account the social approach, ethical perspective and psychological comprehension of the moment of mourning where donation is considered, and especially, respect to the potential donors' and families' right to independence.

TWO DECADES OF KIDNEY PRE-TRANSPLANT PSYCHOLOGICAL EVALUATION: PATIENT’S PROFILE

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Paula Silva Kioroglo¹, Ms., chpsicol@santacasasp.org.br
3. Yvothy A. Sens¹, Mrs., MD, chpsicol@santacasasp.org.br
4. Luis A. Miorim¹, Mr., MD, chpsicol@santacasasp.org.br
5. Pedro Jabur¹, Mr., MD, chpsicol@santacasasp.org.br

**Introduction:**
The psychological evaluation of the adult kidney transplanted analyzes the emotional condition to deal, adjust to the new life condition and adherence to treatment.

**Aim:**
To track data obtained through the receptors' kidney pre-transplant psychological evaluation protocol. **Method:** 100 receptors' psychological protocols were analyzed (1990 - 2007).

**Results:**
54% of the patients were female and 46% male. 65% did not have any psychopathological records previous to renal pathology, however, along with the renal pathology, 79% presented adjustment reaction. 61% presented good intellectual resources, comprehension regarding transplant was good for 58%. The dialysis treatment was done by 93%, with 86% of total adherence. Total adherence to diet took place in 59%, partial in 39% and was not followed by 2%. 72% adhered completely to the reduction of liquid ingestion, 24% partilly and 4% did not adhere. The patients with a potential live donor were 32% of the sample, and there was a satisfactory connection between them in 87.5%. The dead organ donor was considered by 68% of the patients. The information about the transplant was adequate for 44%. The expectations were positive for 82%. 63% presented specific fears facing the transplant. The emotional resources were considered satisfactory in 50%. The psychological opinion saw that 10% of the patients were not considered suitable for transplant, 52% suitable and 38% suitable but with need for monitoring during surgical period.

**Conclusion:**
Data related to the patient's profile are important to predict how he/she will deal with the treatment proposed and consequently, adhere to it.

TWO DECADES OF PSYCHOLOGICAL EVALUATION OF POTENTIAL KIDNEY DONORS

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato, Mrs, PhD, wlbruscato@uol.com.br
2. Paula Silva Kioroglo, Ms, chpsic@santacasasp.org.br
3. Yvoty A. Sens, Mrs, MD, chpsic@santacasasp.org.br
4. Luis A. Miorim, Mr., MD, chpsic@santacasasp.org.br
5. Pedro Jabur, Mr., MD, chpsic@santacasasp.org.br

The psychological evaluation of potential donors has as its aim to observe the emotional dynamics, psychological functioning and both the manifest and latent reasons for donation. To verify the presence of emotional and financial coercions is made necessary due to the negative repercussions that could be caused by these behaviors in the post-transplant period for both receptors and donors.

Aim: To track data obtained in the pre-transplant psychological evaluation protocol of potential kidney donors.

Method: 34 potential donor protocols were analyzed (1990 - 2007).

Results: The group of potential donors was 62% female and 38% male. 76% of these did not have psychopathological records. The intellectual resources were considered good for 76% of them. The quality of life was satisfactory for 53%, regular for 41% and unsatisfactory for 6%. The connection with the receiver was evaluated as satisfactory in 88% of the cases and regular in 12% and the emotional implications observed for the transplant situation were considered without unreal expectations for 85%. Regarding the expectations about transplant, 79% were predominantly positive. The emotional state relative to transplant was considered without evidence of a non-adaptive emotional state for 47%, adjustment reaction in the context of transplant for 32% and non-adjusted reaction in the context of transplant for 21% of the donors. Hence, the emotional resources presented by the donors were satisfactory for 71%, leading to a favorable psychological opinion towards donation for 70% of the donors; 12% were considered suitable, but with a recommendation for handling during surgical period and 18% were not recommended.

THE VALIDITY OF THE CGI SEVERITY AND IMPROVEMENT SCALES AS A ROUTINE OUTCOME MEASURE

INSTITUTIONS
1. Barwon Health, Australia
2. University of Melbourne, Australia
3. Healthscope, Australia
4. Monash University, Australia

AUTHORS
1. Thomas Callaly
2. Tom Trauer
3. Seetal Dodd
4. Michael Berk

Objective: The Clinical Global Impression Scale (CGI) is established as a core metric in psychiatric research. This study aims to test the validity of CGI as a clinical outcome measure suitable for routine use in a private inpatient setting.

Method: The CGI was added to a standard battery of routine outcome measures in a private psychiatric hospital. Data were collected on consecutive admissions over a period of 24 months, which included clinical diagnosis, demographics, service utilisation, and four routine measures (CGI, HoNOS, MHQ-14 and DASS-21) at both admission and discharge. Descriptive and comparative data analyses were performed.

Results: Of 786 admissions in total, there were 624 and 614 CGI-S ratings completed at the point of admission and discharge, respectively, and 610 completed CGI-I ratings. The admission and discharge CGI-S scores were correlated (r=0.40), and the indirect improvement measures obtained from their differences were highly correlated with the direct CGI-I scores (r=0.71). The CGI results reflected similar trends seen in the other three outcome measures.

Conclusions: The CGI is a valid clinical outcome measure suitable for routine use in an inpatient setting. It offers a number of advantages, including its established utility in psychiatric research, sensitivity to change, quick and simple administration, utility across diagnostic groupings, and reliability in the hands of skilled clinicians.

FACILITATING ADJUSTMENT OF COGNITIONS AND EMOTIONS (FACE©) IN BIPOLAR AND ADHD ADULTS

INSTITUTIONS
1. Hospital Simone Veil, Psychiatry, Paris, France
2. Vrije Universiteit Brussels, Psychology and Educational Sciences, Brussels, Belgium

AUTHORS
1. Leon-Patrice Celestin, Dr., MD, celestinlp@celestin.info
2. Smadar Celestin-Westreich, Prof. Dr., PhD, Smadar.Westreich@vub.ac.be

Background: Recent findings into cognitive-executive and emotion regulation deficits in adults with Bipolar Disorder and/or ADHD facilitate understanding of how these difficulties may affect quality of life and contribute to addictive responses to stress. Such insights, however, largely remain to be implemented into practice.

Method: This paper integrates findings from the current neuroscientific database into the FACE©-model, which translates the above insights into a systematized multidisciplinary program. Using a mixed-method bottom-up and top-down design, practice implementation of this model is illustrated with cases of consecutively admitted adults’ open access to a first-line mental health centre in suburban Paris over a three month course.

Results: Consistent with previous application to Bipolar/ADHD youth and their parents, clear-cut intervention improvements come forward within a relatively brief time span from the current FACE©-service implementation with adults. All clients presently investigated consulted primarily for single or multiple types of substance abuse. Therapeutic progress foremost includes programme adherence among long-time treatment-resistant clients. Benefits also appear largely ascribable to adequately addressing untreated underlying disorders, chiefly including Bipolar Disorder, ADHD and childhood trauma, into the therapeutic paradigm. Caregiver and patient self-reported (Achenbach’s ABCL/ASR) benefits further include increased insight in and mastery over cognitive-emotional regulation, facilitating control of addictive responses to stressful situations.

Conclusions: Application of the FACE©-program, by actively engaging the client in a scientist-practitioner model along with rigorously implementing evidence-based assessment and intervention, appears to systematically foster therapeutic adherence and outcomes. Further research and practice implications for larger scale and longer-term outcome evaluations are outlined.

VIOLENT BEHAVIOR AND VICTIMIZATION OF PERSONS WITH SCHIZOPHRENIA - REVIEW OF STUDIES

INSTITUTIONS
1. First Faculty of Medicine, Charles University, Psychiatric Clinic, Prague, Czech Republic
2. 7th Field Military Hospital, VÚ 6900, Hradec Kralove, Czech Republic

AUTHORS
1. Martin Cerny, MD, dr.cerny@centrum.cz
2. Ilja Zukov, MD, CSc., ilja.zukov@seznam.cz
3. Jan Vevera, MD, PhD, janvevera@centrum.cz

Objective: Patients suffering from schizophrenia commit violent acts more frequently than general population. On the other hand they are also more likely to be victims of a violent behavior. Recent research proved that they were more likely to be victims of a violent crime than to be arrested for one. The purpose of this study was to analyze how many studies investigated violence committed by psychiatric patients and how many studies investigated violence towards patients with schizophrenia.

Methods: A detailed PubMed analysis (key words: 1. schizophrenia violence, 2. schizophrenia victimization) was performed and relevant studies were reviewed.

Results: Totally we founded 818 studies for keywords schizophrenia violence and violence and 52 studies for keywords schizophrenia victimization. From those 870 studies 244 studies provided relevant information regarding violence or victimization or both in patients with schizophrenia. Almost I (n=176) of all relevant studies (72%) measured violent behavior committed by schizophrenic patients, while only 23% (n=55) measured violence behavior towards schizophrenics. Only 5% (n=13) studies studied both - violence committed by patients and violence towards those patients.

Conclusions: While the majority of studies analyzed violent behavior of schizophrenic patients, only few studies investigated violence and abuse that schizophrenics experience from the community.

MENTAL HEALTH SERVICES AND INDIGENOUS ISSUES IN CONTEMPORARY POLYNESIA

INSTITUTIONS
1. University of Hawaii at Manoa, Anthropology, Honolulu, United States

AUTHORS
1. Shanna M. Clinton¹, MA, sclinton@hawaii.edu

Increasing incidence of mental illness is growing global concern, but is especially problematic among indigenous peoples in modernized/modernizing societies. Psychiatric research and practice, public mental health systems, and other social service programs have made significant efforts to address the burden of psychiatric disorders. But they have not sufficiently incorporated cultural awareness, social support, and consumer-congruent explanatory models, which are especially important in indigenous mental healthcare. This paper investigates the incidence and nature of mental illness, and the programs which address it, in contemporary Polynesia. Special attention is paid to the situations of Hawaii and New Zealand/Aotearoa as having high rates of mental illness and numerous treatment institutions, and these are contrasted with smaller and less developed nations in the Western Pacific. The issues around these discrepancies provide examples for understanding more global mental health disparities, especially for marginalized indigenous peoples. Some culturally-specific programs for indigenous mental health are described and their value in responding to the populations’ unmet needs and illuminating flaws in psychiatric theory and practice is elaborated.

Psychiatric illnesses, especially depression, may affect a person’s ability to respond to behavioral interventions. In a study of high risk crack cocaine using women, recruited from street based community outreach, we had the opportunity to evaluate the effect of DSM-IV depression on changes in HIV risk behaviors. Women were randomized into the NIDA standard vs. an enhanced, behavioral, peer-delivered intervention and followed at 4 and 12 months. High response rates were achieved at each wave. The sample of 304 women, who completed all 3 waves, were stratified into 3 groups: those who currently met criteria for depression and those who never did. Lifetime, but not currently depressed, were excluded. Depressed women differed from never-depressed women on race, sex trading, but not arrest history, homelessness, marital status and education. Depressed women, compared to never depressed women, were more likely to meet criteria for alcohol dependence, ASPD, and PTSD. Interactions between depression status and assigned intervention at 4 and 12 months will be analyzed to assess the effect of depression over time on number of crack days per month and number of sexual partners. HIV interventions should take into consideration the mental health status of respondents, in the community.

COLLABORATIVE CARE IMPLEMENTATION IN MENTAL HEALTH SYSTEM

INSTITUTIONS
1. Secretaria Municipal de Saúde de Florianópolis, Brazil

AUTHORS
1. Evelyn Cremonese¹, MD, evelyncremenese@yahoo.com.br
2. Sonia A Saraiva¹, MD, soniasaraiva@hotmail.com

OBJECTIVES: To describe the implementation of collaborative care in mental health system in Florianópolis, a state capital in southern Brazil.

METHODOLOGY: Experience report.

RESULTS: The family health policy, current model of primary care in Brazil, is composed of interdisciplinary teams that act in regionalized form, with defined population under their responsibility. The challenge is to implement beyond borders with the goal of effectiveness. Inside this perspective, a reorganization of the Mental Health system was started. The action of mental health professionals were disarticulated, only in sub-specialized ambulatories, with great waiting lists without risk evaluations and without continued care. Since 2006, the mental health system has been reorganized based on necessities of primary care. Regular meetings between mental health and family health teams have been legitimized, where the cases and strategies of action are presented and evaluated, with advantage it offers in their practice and professional education. It becomes a shared attention, allowing continuity a care and ensuring appropriate treatment.

CONCLUSIONS: Collaborative care is an integrated approach health care in which primary care and mental health providers partner to manage the treatment of persons with mental health problems. This model allowed risk evaluation, end of waiting lists, and increased access to mental health professionals, bringing better security to primary care professionals dealing with mental health. Obstacles that still need to be addressed are the great resistance of the professionals to work collaboratively and human resources reduced.

INTEGRATING PSYCHIATRISTS WITHIN PRIMARY HEALTH CARE

INSTITUTIONS
1. Secretaria Municipal de Saúde de Florianópolis, Brazil

AUTHORS
1. Evelyn Cremonese¹, MD, evelyncremenese@yahoo.com.br
2. Sonia A Saraiva¹, MD, soniasaraiva@hotmail.com

OBJECTIVES: To discuss the role of the psychiatrist in primary care.

METHODOLOGY: Experience report.

RESULTS: Originally, graduate medical education in Brazil was based on the individualized clinic and hospital-based care, with little integration with other health professionals. However, the change in the health care system and the Psychiatric Reform gave preference to the decentralization of health services and to community-based care, which urged the re-evaluation of the psychiatrist role. In Florianópolis, southern Brazil, the psychiatrists used to practice in specialized ambulatories with no contact with other professionals of primary care. There were long waiting lists and no risk evaluations. As a consequence, the model of attention was redesigned based upon the National Health Department's recommendations, with family health centers as the main coordinators of care. Psychiatrists then begin to work within the collaborative care model, giving support to family health teams’ demands whilst restructuring its own practice. In this model, new strategies for intervention, admissions and evaluation are adopted. The referral method, which tends to favor fragmentation and irresponsibility, was substituted by the notion of co-responsibility.

CONCLUSIONS: Such changes have propitiated the union between health care providers and the organization of referral system to mental health based on risk evaluation and coordinated work. It also favored the continuous education and inter-disciplinarian work, as well as bringing the psychiatrist closer to the community.

OBJECTIVES: Describe the experience in planning a new technical-assistance model in mental health care, with the various obstacles and opportunities in the reorganization of the mental health system.

METHODOLOGY: Description of experience.

RESULTS: The mental health system of Florianópolis, the capital of Santa Catarina state in Southern Brazil underwent a process of re-modeling in mental health care after the detection of its fragmentation, with mental health professionals working in an isolated form and the need for integration with primary care based on Family’s Health Strategy. The process consisted of different stages: approach, proposal, construction and evaluation in conjunction with the health care providers. The main strategies were: organization of the mental health care based on the Family Health Team (FHT), in regionalized form, with collaboration between Family Health and Mental Health Teams (MHT); coordination of the different mental health resources (FHT, MHT, Centers of Psychosocial Care and hospitals); design of treatment protocols and reorganization of the pharmaceutical care; and the offering of psychological support groups for the FHT.

CONCLUSIONS: Besides being a slow process with conflicting positions between different social actors, this restructuration is providing a unification of the different health resources and the adoption of integrated interventions, resulting in better health care for the population.

MENTAL HEALTH SERVICE IN SHORTAGE CONDITIONS AND CRISIS - THE LAST CALL FROM CUIAVIA-POMERANIAN REGION IN POLAND

INSTITUTIONS
1. Collegium Medicum N. Copernicus University, Dept. of Psychiatry, Child and Adolescent Ward, Torun, Poland
2. County Psychiatric Treatment Center (WOLP), IV th Clinical Dept. of Psychiatry, Torun, Poland
3. Medical University in Gdansk, Dept. of Psychiatry, Gdansk, Poland

AUTHORS
1. Miroslaw R Dabkowski¹, MD, PhD, domirka@uni.torun.pl
2. Mieczyslaw S Janiszewski², MD, PhD, mjanisz@wolptorun.pl
3. Alina M Wilkowska³, MD

The crisis of mental health service (MHS) within all Poland regions is seen in: - low level and even deepening every year lack of human resources in every MHS profession - insufficient indices in in-patient MHS (approx. 3.5 beds per 10 thousand inhabitants) - the only bankroll rule of MHS is "payment for service" - collapse of outpatient non-private MHS - the waiting list appoints visit up to 100 days - short outlay proportion for MHS (for psychiatry: approx. 3% of total health service funds) - insufficient financing of MHS providers (procedures are underpay - below reimburse) - decay of money absorptive and time consuming services (e.g. psychotherapy, family approach)

Crisis: 1 Jan 2008 - the breakdown of MHS in the Region - enforcement of EU Directive of doctors’ employment time. Attempts of trade unions of medical professions to improve their SES (“to earn more than a half of average salary in Poland”) Prognosis: - substantial limitation of accessibility to MHS, discontinuation of treatment - significant lose in quality of MHS - increasing of medical professions diverge from MHS (migration and to other professions) - government and local authorities quit onus for MHS - MHS evolution stunts (transitions from traditional, “big hospital/asylum” model to community psychiatry is impeded) This is the last call to introduce systemic changes.

AUTHORS
1. Ivan David¹, Dr., david@plbohnice.cz

Since the 17th century the approach the mentally ill has still been changing. Tendency to protect the mentally ill tends to release them from the jails to the psychiatric hospitals. The human effort to protect the ill from the conditions in the overcrowded and poor, not sufficiently funded psychiatric hospitals, tends to release the patients to the outpatient care. But the outpatient care is usually not ready for this and more over rather a great part of the ill suffers not only from psychosis but also from anosognosia. The reformers of psychiatry either do not know, or they are disregardful that the chance to cure the mentally ill expertly, though not voluntarily, will disappear. In services offer which is not sufficient this necessitates to homelessness and criminalization of the mentally ill. The aim of the paper is to compare the situation in some countries which go on different ways and achieve different results. The best results has been achieved in such countries which are proposing the goals from the economic point of view achievable and the planned changes will not cease halfway, when the care for a big number of the mentally ill is not ensured. The projects of changes of the psychiatric care organization must be evidence based and not ideology based, they must be prepared with regard to secure all the real needs of all the patients including those suffering from anosognosia, and this must be assured by sufficient funding of the whole project.

PSYCHIATRIC HOSPITALIZATION OF CHILDREN AND ADOLESCENTS IN A PRIVATE GENERAL HOSPITAL

INSTITUTIONS
1. Clinica las Condes, Psychiatry, Santiago, Chile

AUTHORS
1. Flora M De la Barra¹, Dr., torbarra@gmail.com
2. Garcia S Ricardo¹, Dr., MD, ricardo.garcia.se pulveda@gamil.com

Aims: To describe characteristics of 41 children and adolescents admitted to an acute treatment psychiatric unit in an 18 months period, discuss results, and analyse benefits and weaknesses of this modality.

Method: 262 patients were admitted, 15.45% of which were under 18 years of age, whose case notes were reviewed.

Results: 18 were girls and 23 boys. Mean stay was 3.58 days. Main reasons for admittance were suicidal behavior (29.3%), psychomotor agitation/ acute conduct disturbance (24.4%), psychotic behavior (12.2%). At discharge, 43, 9% were diagnosed as suicidal, 1/3 of which suffered depression. Psychosis were documented in 22%, emotional disorders in 19.5%, 46, 3% had abnormal personality development. Family dysfunction was present in 53,15%. Psychopharmacologic treatments were prescribed in 63, 4% of the patients: atypical antipsychotics 58, 5%, mood stabilizers 24.3 %, benzodiazepines 24.3%, SSRIs 12.2%. All patients received psychotherapeutic, family and psychosocial interventions.

Discussion: This treatment model is the first implemented in Chile in the private sector. In a short stay, it was possible to control and stabilize severe psychiatric pathology, perform precise diagnoses and intensive treatment. The unit was evaluated as technically efficient by the administration and joint evaluation commission. Due to high demand of medical-surgical beds, low reimbursement by insurance companies and marginal profits, it was decided to reconvert the unit, maintaining psychiatric hospitalization when necessary.

This results are discussed in the framework of literature reports.

3. Hamid Ashkani1, Dr, MD

Background: It has been long recognized that the practice of medicine is stressful and that medical students are prone to psychological problems. The aim of this study was to determine the personality characteristics, mental health, stressors and coping skills of first year students of Shiraz University of medical sciences.

Materials and Methods: This is a descriptive study, 102 first year medical students were randomly selected. They were subjected to fill demographic questionnaire, General Health Questionnaire-28, psychosocial stressors Questionnaire of Medical student, coping strategies - Revised Questionnaire and NEO-FFI.

Results: Analysis of data revealed that 42.2% of medical students were suspected to suffer from a variety mental disorder. Medical students who came from region 3 showed more anxiety than other regions (p<0.014). Male medical students used significantly more problem focused coping skills that females (p<0.03) female medical students used significantly less useful coping skills than male students. Female medical students received high score in Graduate subscale of psychosocial stressors Questionnaire than male students (p<0.001). Personality characteristics did not show any differences between males and females.

Conclusion: This finding suggests further psychological evaluation and adequate counseling services to promote medical students mental health.

INTRODUCTION The treatment of patients with mental disorders has traditionally suffered from a paternalistic social and political attitude with little respect for autonomy. In this era of neuroscience, where we are challenging old concepts of psychiatric taxonomy, diagnosis and related treatment, still this remains the case. We advocate monotherapy for distant disorders, but we practice polypharmacy for comorbid disorders and personality states, giving often inadequate reasoning for such practices.

METHODS Through thorough research of main medical databases and web search engines relevant data was scrutinized independently.

RESULTS In spite the fact that a definition for mental disorder and certainty about diagnosis continue to be elusive issues, we are extremely determinist concerning treatment modalities. The apparent gap between insufficient empirical evidence and the need for a decisive practice creates many ethical considerations which, till now, are focused on promoting "security" for the practitioner and the patient.

CONCLUSION Apparently that is the right avenue to pursue but in our view the gap still remains and, in the end of the day, with what it is concerned most is the maintenance of an "infallible" medical paternalism anxious to protect a presumed intrinsic goodness. We propose that a research for an ethical framework should also take into consideration "uncertainty" as the only "safe" ground for practice exposing the gap and filling it with genuine intellectual honesty.

IS THERE A NEED FOR STRUCTURED ASSESSMENT OF COMPETENCE OF TREATMENT DECISION?

INSTITUTIONS
1. Psychiatric Hospital of Attika, Dafni, Athens, Greece

AUTHORS
1. Christos Tsopelas¹, Dr, MD, MSc, tsopelas@gmail.com
2. Anastasios Dimopoulos¹, Dr, MD
3. Ilias Vlachos¹

Aims
Although treatment decision is respected in patients with physical illnesses, that's not the case with mentally ill patients. Competence to decide for their own treatment is decided by the assessing psychiatrist without clear rules, influenced mainly by the compulsory status of the admission and the absence of unambiguous guidance.

Methods
In depth literature research of medical and law databases have produced relevant articles. Further research with web search engines revealed extended arguments regarding these issues. Two researchers have independently done research and assessed all data before reaching consensus about the appropriate data.

Results
There is a common understanding that compulsory admission presupposes diminished capacity for decision making. Though most of the times this is considered to be true, it is not always the case and often the capacity of the patients for making decisions is underestimated. This in part is due an inherent prejudice of the physician towards the cognitive and emotional abilities of the patient. Furthermore, the initial assessment is taken quite always as granted, framing in that way a rigid interaction between psychiatrist and patient concerning the treatment plan.

Conclusions
The capacity of decision making of the mentally ill patient, whether or not being compulsory admitted, should be assessed in a more holistic and systematic approach and become part of the standard practice. The structured approach could improve also dissemination and approval of analogous decisions to all relevant parties, such as service users, carers and legal services.

DO MENTAL HEALTH SERVICES MEET USERS’ NEEDS?

INSTITUTIONS
1. Wroclaw Medical University, Department of Psychiatry, Wroclaw, Poland

AUTHORS
1. Ewelina Dobrzynska¹, Dr, PhD, edobrzynska@poczta.fm
2. Joanna Rymaszewska¹, Dr
3. Dorota Frydecka¹
4. Andrzej Kiejna¹

Objective:
Clients’ satisfaction with mental health service is one of necessary conditions of good treatment outcomes. The aim of the study was to investigate satisfaction with treatment and its dependency of users' needs and their subjective quality of life.

Methods:
The sample of 174 out-patients with schizophrenic, affective, anxiety, eating and personality disorders were assessed with the Brief Psychiatric Rating Scale (BPRS), the Camberwell Assessment of Need Short Appraisal Schedule (CANSAS), Manchester Short Assessment of Quality of Life (MANSA) and the Client's Scale for Assessment of Treatment (CAT).

Results:
1. The mean result of CAT was 8.2 [SD=1.5] and the half of patients assessed their satisfaction with treatment between 7.2 and 9.2 (on 1-10 scale). Persons with eating and personality disorders were the least satisfied with services.
2. The highest numbers of met/total needs were connected with health and unmet needs with social area. Total unmet needs of persons with schizophrenic, eating, personality and affective disorders were significantly higher than among patients with anxiety disorders.
3. Persons with personality, affective and eating disorders had significantly lowest subjective quality of life.
4. Satisfaction with treatment had negative correlation with unmet needs (mostly health and service needs), intensity of depressive/anxiety symptoms and positive correlation with subjective quality of life.

Conclusions:
1. Social needs were the most often unmet from patients' point of view.
2. The higher unmet needs and more intensive symptoms of depressive/anxiety were, the less patients were satisfied with treatment and the lower they assessed their quality of life.

3. Adriana Vitalli¹, Mrs

In a total of 3940 Psychiatric Evaluations, the Adjustment Disorder constitutes the psychiatric pathology that most frequently appears in the interviews of employees in psychiatric examination in disorders with more than 30 days of evolution and in conditions of labor absenteeism. It is to emphasize that in these evaluations, stories associated to labor harassment prevail, without being associated to an increase of efficiency or effectiveness in the labor. In this study we detected that this psychological harassment is occasioned not only from the chiefs to the subordinate personal, but also among mates. We also found that certain hierarchy personnel are also harassed by specific groups of employees. In the evaluated group we found that the associated psychiatric disorders to mobbing were: Adjustment Disorder (32.5%) Mixed States of Anxiety and Depression and Generalized Anxiety Disorder (21.7%), and Depression (21.9%). One of the tests used in this study group was the Rorschach, which made it possible the analysis, differentiation and validation of the Adjustment Disorders especially stress tolerance. It also discriminates among personality features - stable characteristics - and symptoms or behavior reactions that are caused by environmental stress. The above mentioned Test may be useful in the analysis of the correlation between Adjustment Disorders and Personality Disorders.

The Recovery Movement in the United States is part of a larger social movement among individuals with serious mental illness focusing on empowerment and self-determination. The American Psychiatric Association has adopted recommendations for its members to “contribute to the development of best-practice guidelines that describe a range of approaches that support recovery goals.” This presentation focuses on an example of best-practice practice guidelines developed by a group of multi-disciplinary practitioners and recovering consumers to support the recovery of individuals with severe mental illness. A review panel provided additional support and critique in the development of the Recovery Standards Manual and included nationally recognized advocates in the recovery movement. The Recovery Standards Manual action-guidelines, developed for recovery-oriented practitioners, are presented with definitions for each guideline, their strategic importance, and specific activities to support their implementation with patients.

URBAN YOUTH VIOLENCE AS A MENTAL HEALTH ISSUE: KILADELPHIA: AN AMERICAN CITY

INSTITUTIONS
1. Strategies For Well-Being, LLC, Medical Ethics, Yeadon, United States

AUTHORS
1. Glenn Ellis1, Mr., glenn@glennellis.com

Youth violence in the United States has emerged as a major concern for communities. There is some evidence of a relationship between serious mental disorders and violence in adolescents or young adults in the general population. Youths exhibiting multiple, persistent violence were more likely than were their nonviolent peers to have such other problems as substance use, nonviolent delinquency, academic problems, and poor mental health. The designation of youth violence as a public health issue complements the more traditional status of the problem as a criminal justice concern. Studies suggest that of the one million youth who come into contact with the juvenile justice system, as many as 60% of those incarcerated may have a mental health disorder and as many as 20% may have a severe disorder. Kiladelphia is the name that, in some circles, is being given to Philadelphia, PA after the murder rate jumped to 406 killings in 2006, and almost 400 in 2007. 85% of those killed were African American youths. This presentation will look at the current trends in the city with youth violence, and the corresponding statistics around the lack of mental health care provided to them leading to their acts of violence.

ATTITUDES TOWARDS PSYCHIATRY IN THE MEDICAL SETTING

INSTITUTIONS
1. Children Cancer Hospital 57357, Psycho-oncology, Cairo, Egypt

AUTHORS
1. Mohammad Ibrahim ElShami1, Dr., mohammad.eshami@57357.com

The stigma attached to mental illness in Egypt is one of the greatest obstacles to the psychiatry field as a whole and the medical student’s career choice in psychiatry. We propose that medical students and staff hold a negative attitude towards psychiatry and mentally ill patients. This in turn affects the psychiatry students’ career choice and the medical services offered.

Aim/objectives This work aims at measuring the attitude of medical staff and medical students to the psychiatry field and mentally ill patients. Furthermore, we aim at acquiring knowledge to further revise the undergraduate psychiatric clinical course in the medical school, and to further advance the liaison psychiatric consultation.

Methodology The study will take part at the faculty of medicine, Cairo University Hospital, Egypt. The study population will include medical students divided into two subgroups each one contains 100 students. First subgroup is 1st year medical students and 6th year students. The second subgroup is medical staff. 50 members will be recruited. The observation period will span over a period of 5 months. All the subjects will be asked to anonymously complete a questionnaire. This questionnaire is constructed to cover the following dimensions: attitudes towards psychiatric services and treatment, causes of mental illness, human rights of mentally ill patients, stigmatization of mentally ill patients, psychiatric career choice and attitudes towards psychiatrists. The study-specific questionnaire was developed through in-depth interviews and then constructed and run a pilot study on.

Results & Conclusion Work in progress

The work is recognized as it founds an individual and social significant function, support of psychism. Given the significant representation of the known inscript in the psychism and pulsional balance, and subliminal channel. This investigation tries to make an updated description about the disturbances in the psychism and psychic pathologies, associating subjective suffering to the involuntary loss of the labor activity and to know the different beliefs, valuation and conformation of the identity responding to this problematic, within people of different classes and age range. The sample is constituted by 400 Ss of different social and educative levels, sorts and ages, being in labor age and next not to retire. The measure in this general sample is a semistructured survey that includes sociodemographic standards and indicating items (DSM) of clinical symptoms, syndromes and psychosomatic diseases that are hoped to be found in the blanc population. In a subsample of 20 Ss, deeper interviews were made to release specific qualitative data to the training targets. The correlational descriptive data will work with program SPSS/PC and it will be integrated to the qualitative analysis. The methodology that it will be used is descriptive with qualitative and quantitative data.

AIM: EMILIA is a sixth framework European Project that is aimed to improve social inclusion of mental health service users by challenging the conventional role of users and professional. The implementation of EMILIA is the move towards the empowerment of the users, the recognition of their expertise in the field of mental health and the use of this knowledge to help mental health institutions learn and develop. EMILIA introduces the concept of the user as an expert.

METHODOLOGY: The innovative aspect of this Project is that users participate as researchers and teachers while at the same time forming part of the study group. Based in the methodology of Life Long learning:LLL, a group of patients, staff and family members undergo a training programme designed by EMILIA: social network support, recovery, families, employers/employees, with the aim of recognising the user as an expert.

RESULTS: The Project is two years old and after a year and a half research and training design phase the first training modules have just started with users, staff and families. Various changes have occurred in order to convert conventional mental health care centres into learning organisations. Base-line studies were undertaken and will be repeated through the Project to measure this shift.

CONCLUSIONS: The EMILIA Project requires a change in perspective and attitudes among mental health professionals, users and family members to allow for the empowerment of users.

3. Vera Lucia Mendiondo Osinaga 1, Doutor, PhD, wosinaga@terra.com.br

Introduction: This study aimed to discover possible factors conditioning patients’ knowledge about their diagnosis at three psychiatric services (Emergency Unit, Outpatient Clinic and Psychosocial Care Center - NAPS). Methodology: We interviewed 125 mental patients and their companions at each of the three services, located in Ribeirão Preto (n= 750). In the multivariate analysis, gender, civil status, education, family relationship, complaint, serious diseases, treatment, earlier hospitalizations and age were studied in relation to the dependent variable Agreement among diagnoses informed by patient, companion and records. In the logistic regression, the variables were maintained with coefficients different from (α = 0.05). The Odds Ratio was used for comparison. Results: Agreement levels at the services were: 22.4% (EU); 26.4% (NAPS) and 24.8% (Outpatient Clinic). Logistic regressions presented significant effects according to the Chi-Square test. Knowledge about medical diagnosis was conditioned differently at the three services. The following variables displayed significant prediction power: Age, Gender, Education, Earlier Hospitalizations, Severe Illnesses and Treatment.

This study aimed to present the profile of professionals who act in mental health services in São Paulo, state focusing on the nurse’s practice. Questionnaires and semi-structured interviews were performed with 114 professionals of three hospital psychiatric and five extra-hospital services. The results indicate teams with nurses (31%), physicians (29%), psychologists (16%), social workers (11%), occupational therapists (7%) and other professionals (6%). Female gender is predominant (73%), age between 24 and 68 years old. Of these professionals, 46% attended to specialization courses in mental health and 33% are specialized in other areas. All of them perform individual assistance in the development of therapeutic practices, 55% attend in group and 73% attend families. Of these, 43% work alone or with another professional, predominantly in 41% with soci

al workers. Nurse’s actions focus on the patient’s observation (41%), taking notes of behavior (40%), administering medication (38%), physical comfort and vital signs (35%). Therapeutic interactions are also involved (33%), recreational activities (27%) and observations of the patients’ sleep patterns (23%). The management function in the units were performed by 26% of the nurses; other professionals summed together 28% of those who managed the Unit. It is concluded that nurses are more represented in teams and their activities involve interaction with the mental patient, consolidating the interpersonal relation practice. In addition, the nurse is collaborator in the mental health teams with other professionals, in the assistance to families and groups of patients, and is also manager of mental health units and of team of auxiliaries.

ADHERENCE TO ANTIRETROVIRAL TREATMENT: MOTIVATION ASPECTS

INSTITUTIONS
1. Medicine and public health school, Psychiatry, Salvador, Brazil
2. Universidade Federal da Bahia, Infectology, Salvador, Brazil

AUTHORS
1. Rosa Garcia¹, Dr., PhD, pssiquiatria@uol.com.br
2. Roberto Badaró², Dr., PhD, pssiquiatria@uol.com.br

It is now possible to achieve extreme reductions in the numbers of viral particles in the peripheral blood of HIV-positive patients undergoing treatment. However, the strict therapeutic regimens required, the number of pills, adverse events and the stigma of a disease that requires the patient to introduce pill-taking into his/her lifestyle brings into question one aspect of mental health, which is motivation to do that which is being proposed. We investigated the influence of each of the components of the adherence trilogy: information, motivation and behavioral abilities, as risk factors in a population of HIV-positive/AIDS patients undergoing antiretroviral treatment in the city of Salvador, Bahia, Brazil. Methods: An intervention study was carried out by introducing motivational assistance into the routine recommendations for the treatment of patients who were initiating antiretroviral (ARV) therapy. Seventy-six treatment-naive patients, who had been selected to initiate ARV therapy, were included. These patients were divided into two groups. Group A, in which the regular routine of the institution was followed, received information on the disease and its treatment; patients in group B had the same routine, but they were also followed-up fortnightly and given motivational intervention. Evaluations of viral load and CD count before and following treatment were used to measure adherence. Results: There was no significant difference between the two groups. Conclusions: As the rates of non-adhesion were at the lower limits of the ranges reported in the literature, it would appear that providing motivation and information can be of help to the patient.

PRACTITIONERS’ REALITIES: ISSUES, PROBLEMS AND STRATEGIES IN THE SUPERVISION OF MENTAL HEALTH PROFESSIONALS

INSTITUTIONS
1. Northern Illinois University, Counseling, Adult and Higher Education, DeKalb Illinois, United States
2. Johns Hopkins University, Counseling and Human Services, Rockville, Maryland, United States

AUTHORS
1. Francesca Giordano¹, Dr, Ph.D., fgiordano@niu.edu
2. Mary Guindon², Dr., Ph.D., mguindon@jhu.edu

Bernard and Goodyear (2004) define clinical supervision as an intervention provided by a more senior member of a mental health profession to a more junior member of that profession. This relationship is evaluative, extends over time, and has the simultaneous purposes of: enhancing professional functioning of the more junior person, monitoring the quality of professional services offered to the client and serving as a gatekeeper of those who are to enter the particular profession. Many mental health professionals experience problems obtaining effective, ethical supervision. These problems may be linked to the failure of educational and community-based setting to provide supervision training. Based on data gathered from mental health professionals, in Illinois within the United States, with more than five years clinical experience, this session will explore their concerns related to their experiences as supervisors, supervisees, and administrators. Additionally, this session will explore models of supervisee and supervisor development, ethical issues in supervision and the training needs of supervisors.

THE VALUE OF LIFELONG LEARNING AS A RECOVERY RESOURCE

INSTITUTIONS
1. Middlesex University, London, United Kingdom

AUTHORS
1. Christopher Griffiths¹, c.griffiths@mdx.ac.uk

This research has emerged out of the EU’s Empowerment of Mental Illness Service Users: Lifelong Learning and Action (EMILIA) project which has as two main goals: increasing empowerment and social inclusion.

Aims/Objectives The main aims of this research were to seek out the value of a three part training course for mental health service users from the perspective of the trainers. The research sought to find out what the students gained and also what the trainers - who were also mental health service users - derived from the training. Furthermore suggestions for improving training for service users were sought.

Methods Qualitative analysis of trainer’s focus groups and reflective reports was conducted based around the principles of grounded theory.

Results The results showed that both trainers and students gained greatly from the training. The students gained in terms of their recovery, leadership skills, self-awareness, social inclusion, empowerment, self-confidence, and future orientated motivation. The students came to recognise and accept the fact that they do have particular individual strengths and that they are part of a larger movement of people who are recovering. The trainers expressed the fact that they felt great pride in the success, growth and progress along the journey of recovery shown by their students. The trainers also felt that they were enriched by the experience.

Conclusion Lifelong learning is an important and integral part in the recovery of mental health.

INVESTIGATION OF EMPATHIC TENDENCY PERCEPTIONS ACCORDING TO SPIRITUAL DIMENSIONS OF TURKISH NURSING STUDENTS

INSTITUTIONS
1. Ege University School of Nursing, Psychiatric Nursing, Izmir, Turkey
2. Ege University School of Nursing, Community Health Nursing, Izmir, Turkey
3. Ege University School of Nursing, Izmir, Turkey

AUTHORS
1. Aysun Babacan Gümüş¹, Dr, PhD, aysungumus@hotmail.com
2. Esra Engin¹, Dr, PhD, esraengin@yahoo.co.uk
3. Şafak Ergül², Dr, PhD
4. Hatice Polat³, Mrs

Objective: Empathy is one of the main components of the therapeutic relationship. One of the factors which effects empathic tendency is the individual’s spiritual dimension. Therefore in therapeutic relationship nurses need to be aware of their own psychosocial, emotional and spiritual dimensions. This study was conducted to investigation of empathic tendency perceptions according to spiritual dimensions of Turkish nursing students.

Method: The sample of the research consisted of 400 students of Ege University School of Nursing in Turkey in the academic year 2006-2007. Data was collected with the questionnaire form developed by researchers in line with the related literature (1) and Empathic Tendency Scale (2). Data were analyzed using student t test and ANOVA.

Results: Empathic Tendency Scale mean score of students was 68.22±7.76. There was a significant difference between belief status (F=3.75, p<0.05), worship status (F=8.23, p<0.01), perceptions of relationship with God (F=19.40, p<0.01), perceptions of life (F=3.65, p<0.05), perceptions of death (F=7.35, p<0.01) and Empathic Tendency Scale mean score of students.

Conclusion: According to findings, spiritual dimension affects the students’ empathic tendency. Therefore, in nursing education, spiritual awareness process should be taken into consideration in order to increase the empathic tendency of the students.

Objectives: 1. To identify various mental health delivery models used in the earthquake affected areas of Gujarat, India 2. To study the public perception about their usefulness and acceptability.

Methods: A severe earthquake (6.9 on Richter Scale) rocked the state of Gujarat, India in 2001. As a part of a multi-site study of mental health morbidity and service needs in the earthquake affected population, various service delivery models were identified from the primary and secondary sources of information in three districts of Gujarat viz. Ahmedabad, Bhuj and Rajkot. Primary information was obtained using qualitative research techniques like in-depth interviews, key informant interviews, and focused group discussions in the affected communities and the help seeking behaviour of patients identified in epidemiological survey in the area. Various secondary data sources included health care settings, and scientific reports and documents of various organizations working in the field. Data were analyzed using qualitative analysis.

Results: A variety of service delivery models were used by different agencies to provide mental health services including awareness camps, community outreach clinics, telephonic helpline, mobile health clinics, mental health camps, counseling services, community support groups and group activities, religious/spiritual healing and Yoga services. The majority of these models were perceived by the people as useful and acceptable, albeit within specific contexts and for specific purposes.

Conclusion: Mental health services could be provided using multiple service delivery models which need to be deployed judiciously to different contexts, populations and range of mental health problems in the aftermath of disasters.

FACTORS INFLUENCING PSYCHIATRIC HOSPITALIZATION FROM SHORT STAY WARD, NIMHANS

INSTITUTIONS
1. Chetna Health Center, Psychiatry, Moradabad, India

AUTHORS
1. Neeraj Gupta1, Dr, MD, drneerajgupta@sancharnet.in

Aim: In India, the mental health services are available only in large cities & the number of psychiatric beds available accounts to 0.25 per 10,000 population.[1] thus, all efforts must be directed at ensuring optimal utilization of the limited resources. This may be true for most developing countries. This study aimed to delineate the factors influencing the dispositions of the patient and the clinical decision making process at the emergency ward.

Methods: This was a comparative study of prospective nature where in two groups from short stay ward (ssw)-(a) 50, consecutive patients hospitalized & (b) 50 consecutive patients discharged & treated as out-patient were compared & followed up for the three months to study their clinical status & psychosocial adjustment during the intervening period by using schedules for clinical assessment in neuropsychiatry and global assessment functioning scale.

Results: The admitted group was more likely to have past history of mental illnesses & psychiatric hospitalization; positive family history of mental illnesses; poor drug-compliance; impaired over-all psychosocial functioning; diagnosis of psychosis(53%),esp. affective psychosis; severity of symptoms, esp. psychotic symptoms, suicidal ideation & violent behaviour. socio-demographic variables, patients' familiarity with NIMHANS' employee & the referral letter weren't related with the admission decision.

Conclusion: It is the clinical status of the patient, not the socio-demographic factors which determines his disposition.

3. Leyla Baysan Arabaci\(^3\), Research Assistant, MD, baysanarabaci@hotmail.com

Background: Humor is an important fact to provide homeostasis. It has a great importance in protecting the health and advancing it(1). It is important to investigate the nursing students’ opinions about the humor, who will be the nurses in the future, and to search the effect of their opinions on the healthy lifestyle.

Aims: This research was planned in order to investigate the opinions of the nursing students about humor and the effect of this opinions on healthy lifestyle behaviors.

Methods: The describing research was held with 291 students educating in 2., 3. and 4. classes at Ege University, School of Nursing from March until April, 2006. Data were collected with 2 questionnaire form. The “Healthy Lifestyle Behavior Scale” consists of 6 sub-groups and each sub-group of the scale was evaluated independently. Data were evaluated by the number-percent dispersion and correlation analysis.

Results: The students whose mean age was 25 and 32.0% of whom worked as nurses stated that humor helped communication and also 25% of the students stated that humor made the jobs done more enjoyable and more productive. Also, 64% of the students underlined that a lesson including humor must be in the nursing education. It was assigned that the students use of humor were related to their “realization of themselves”, “having the responsibility of health”, “nutrition”, “stress management”, and “interpersonal support” situations.

Conclusion: It was assigned that the students’ situation of using humor were effective on the healthy lifestyle behaviors.

STATE OF MENTAL HEALTH IN UNEMPLOYED PEOPLE IN CONTEXT OF SOCIOCULTURAL DYNAMIC

INSTITUTIONS
1. Mental Health Research Institute, Social Psychiatry Department, Tomsk, Russian Federation

AUTHORS
1. A. V. Gychev\(^1\), Mr., niipz@sibmail.com

Investigation of patho- and sanogenesis of social-stress disorders requires more detailed study of mechanisms of interaction in system “person - social situation” with distinguishing situational and personal variables as well as parameters characterizing their mutual influence.

Objective: To reveal substantially significant macro-social compounds of the situation of forced unemployment we have conducted comparative analysis of state of mental health of unemployed people in interrelationship with some social-demographic indices in 1993 and 2004. As baseline data, we used results of screening-examination of 184 persons, officially recognized as unemployed by public employment service of Tomsk in 1993 and 224 persons, having status of unemployed in public employment service of Tomsk in 2004.

Conclusions: For period from 1993 till 2004, decrease of level of mental health at the expense of enhancement of number of persons with clinically pointed out forms of borderline neuro-mental pathology is noticed. Trend toward “ageing” in all groups of mental health what reflects more harsh requirements of employers to age of potential employees. 3. Basic cause of unemployment currently is his/her own decision of the employee and not reduction of staff or liquidation of the enterprise what was typical for period 1992-1993. Unemployment for this period gradually looses character of extra-personal, incontrollable situation. 4. Subjective assessment of problems of unemployment testifies to decrease of “traumatic character” of unemployment for persons with signs of mental health disturbance. This is one of the indirect proofs of “selectivity” concept in the problem of interrelationships of unemployment and mental health at present.

Trisomy 21 is the most common and best known of all malformation syndromes. The birth prevalence of trisomy 21 is generally 1:650 live birth. Certain signs lead to suspicion of the diagnosis already before the certainty given by cytogenetic test in few days. As a matter of fact new-born child with Down’s syndrome involves not only the child itself but also the parents as well as the whole family. It is not only concerned about to fix the diagnosis but based on the knowledge of the family to schedule who, when and how should announce it to the parents confidentially. The way which the parents are said the fact is very important for the future of everyone involved. The parents come through a psychic crisis that is identical with phases reacting to the death of beloved person: shock, refusal, adaptation, reorientation. The way of a notification can help then to overcome the situation more easily or can traumatise them for a very long time and influence the development of the child secondary impaired through painful experiences of the parents or even abandoned. Parents are very sensitive to every word and tender to every support and compassion given to them. The staff has to undertake responsibility and inform parents about the birth of the child with handicap. It is necessary to prepare the interview properly. It is necessary to deal with the parents as with adults, who are able to face the situation with using the proper help and support.

Aims/Objectives: The purpose of this research is a study of the relationship between managers’ human skills and teachers’ job security.

Methods: Research method is correlation. For this purpose, 292 managers were selected by using the random sampling method. Sample size estimate with use Kerejci and Morgan table. In this research two questionnaires were used: managers’ human skills and teacher’s job security. Face and content validity of questionnaires were established using a panel of experts. In present study five hypotheses was tested. To analyze data, coefficient of correlation and, t-test have been used.

Results: Results of research showed that: 1) There is a significant relationship between managers’ human skills and teachers’ job security ($r=0.453, p<0.05$). 2) There is difference between managers’ human skills in male and female ($t=3.648, p<0.05$). 3) There is difference between teachers’ job security in male and female ($t=1.982, p<0.05$). 4) There is a significant relationship between managers’ human skills and teachers’ job security among male ($r=0.31, p<0.05$). 5) There is a significant relationship between managers’ human skills and teachers’ job security among female ($r=0.623, p<0.05$).

Conclusion: This research indicated that managers’ human skills have role in teachers’ job security. Teachers’ job security and managers’ human skills are difference in male and female.

Key Words: Managers’ Human Skills, Teachers’ Job Security

AN INTERVENTION PROGRAM FOR IMPROVING THE ACCEPTANCE OF CHRISTIANITY AND INCREASING THE PURPOSE IN LIFE AMONG COLLEGE STUDENTS

INSTITUTIONS
1. Nanya Institute of Technology, General Education Center, Taiwan Republic of China
2. Chung Shan Medical University, Department of Public Health, Taichung City, Taiwan Republic of China

AUTHORS
1. Chi-yin Ho, Dr., PhD, waterho93@yahoo.com.tw
2. Hao-Jan Yang, Dr, PhD, hjyang@csmu.edu.tw

Objectives: This is a preliminary study in evaluating the effectiveness of the Christianity Small Group (CSG) based on small-group dynamics on improving the acceptance of Christianity and increasing the purpose in life among college students.

Methods: Sixteen pre-screened college students with low purpose in life were divided into two groups through randomization process: one self-designed 32-hours program (CSG, n=8) and the other an encounter group (n=8), both were lead by the author. The effectiveness was evaluated by a self-designed 35-item questionnaire named Christianity Attitude Scale (CAS). Pre- and post-tests for the scores of the CAS were compared between and within the two groups using multivariate analysis of covariance (ANCOVA).

Results: A very high internal consistency (Cronbach á = 0.98) of the CAS was revealed in the use among college students. In addition, the two main outcomes, i.e., acceptance of Christianity (F=27.83, p<0.01) and the purpose in life (F=30.30, p<0.01), were significantly higher for subjects in CSG than those in encounter group.

Conclusion: The CSG is an effective program in improving the acceptance of Christianity and increasing the purpose in life among college students. Clinicians or counselors may take spirituality or well-being factors into account in the counseling for college students.

In period after the war (1992 - 1995) in Bosnia and Herzegovina, the reform of mental health services was carried out, which considered implementation of community mental health centre's (CMHC), division into departments, and interdisciplinary work (1, 2). The aim of this research was to analyse the obstacles in work of CMHC, during the period 1997-2007.

Methods: Three CMHC from the area of Tuzla Canton which covered approximately equal number of residents, and had approximately equally structure of urban and rural area have been analysed. The work of CMHC has been analysed with aspect to structure of the team, area capabilities, available resources in the community, and community needs. The data were gathered on basis of a questionnaire, which was composed for this research.

Results: During the nine year period of the CMHC existence 939.6±21.5 patients with mental disorders have been treated yearly on average in all three centres. The highest number of patients belonged to the age of 18-65. Regarding the structure of team, in all three CMHC, teams were incomplete; and the working space capacities were inadequate. Organizational link with primary health care presented main obstacle in realisation of preventive programs, and resocialization programs of patients with schizophrenia.

Conclusion: The main obstacle in functioning of Community Mental Health Centres was the organizational belonging to primary health Centres' where the access was oriented on diagnosis.

Objective: To determine incidence of complicated grief in the families of enforced disappearance in the conflict torn Kashmir valley. Complicated Grief is a recently identified symptom complex marked by continued separation distress and bereavement related accompanying traumatic distress. Methods A total of 100 family members who were recruited from a workshop conducted by department of psychiatry and MEDICEN SAN FRONTIERS with family members of enforced disappearances were screened. Results: Complicated Grief was very prevalent, 79% screened positive for complicated grief, PTSD was present in 30% of screened, 41% met criteria for major depressive disorder, 38% neither met criteria for major depressive disorder nor PTSD, even though everybody who met criteria for PTSD had major depressive disorder as comorbidity. Conclusion: COMPLICATED GRIEF is an important diagnosis in this subgroup of population and results into significant distress and dysfunction and hence warrants attention.

Objectives: To assess distress, anxiety, depression, somatization in professionals working in the IT/ITES sectors and correlate with sociodemographic variables. Methods: 100 IT/ITES professionals were identified randomly from consenting companies selected without any bias, and administered the scaled version of General Health Questionnaire - 28 items scale (GHQ-28) and a self-administered survey form to collect demographic data, total professional experience, history of any medical illness, medications, smoking or alcohol use. Results: Common problems noted were feeling constantly under strain (28%), unable to enjoy daily activities (22%), edgy, bad tempered (19%), not satisfied with asks (18%), and not feeling in good health (16%). Symptoms of anxiety, were noted in 13%. Features of severe depression which were significantly more often reported by women were, feeling life not worth living (p<0.002), thoughts of making away (p<0.005) and idea of taking one’s life (p<0.02). 36 % subjects scored above the cutoff score of 4 and could be considered as probable psychiatric cases. Conclusions: Occupational mental health needs adequate attention in IT / ITES companies as the rate of psychiatric morbidity of 36 % is higher than that reported for general population in India. The findings suggest a need of health promotion activities in the IT sector. Acknowledgements: Lundbeck India, Bangalore

THE HELPING WORKERS’ ATTITUDES TOWARDS ATTRIBUTING BLAME AND HELPING INTENTIONS IN DOMESTIC VIOLENCE

INSTITUTIONS
1. National Chiao Tung University, Counseling center, Hsinchu, Taiwan Republic of China
2. National Changhua University of Education, Department of Guidance and Counseling, Changhua, Taiwan Republic of China

AUTHORS
1. Hsueh-Chun Chen¹, Mrs., Md, violachen2003@gmail.com
2. Li-An Kuo², Dr., Phd, lakuo@cc.ncue.edu.tw

OBJECTIVES: This study is to examine the correlation among and prediction of attitudes toward attributing blame, affective reactions and helping intentions among the helping workers.

METHODS: This study uses the Helping Intention Scale and the Domestic Violence Blame Scale, including victim, perpetrator, societal, and situational factors. It is conducted in a purposive sample of helping workers (N=421) from 23 governmental centers for domestic violence prevention in Taiwan. The valid response rate is 56.1% out of 715 questionnaires.

RESULTS:
1. Significant gender, experiences, and training differences are found in attitudes toward attributing blame: (1) Males are more likely to have Victim blame than females; (2) Those with prior experience of violence in their original family or with domestic violence trainings are more likely to have Societal Blame than their counterparts.
2. Significant correlations among attitudes about attributing blame, affective reactions and helping intentions are found, among the sets of canonical factors, affective reactions could explain 9.6% of the helping intentions through the set of canonical factor, naming “Commiserating with an unpleasant man-Making peace with no divorce” (r= .40) in Taiwanese contexts.
3. Attitudes toward attributing blame could predict helping intentions directly or indirectly, i.e., the higher the Victim Blame and the sympathy for the perpetrator, the more the tendency to support the abused women to return home (9.0%).

CONCLUSION: When counseling the abused women, helping workers’ attitudes toward attributing blame and affective reactions predict their helping intentions. In addition, the findings of this study emphasize the importance of domestic violence education.

A COMPARATIVE STUDY OF SOCIODEMOGRAPHIC, CLINICAL AND SERVICE RELATED VARIABLES IN PSYCHIATRIC PATIENTS ATTENDING AN OUTPATIENT FACILITY IN A TERTIARY CENTRE VS. PSYCHIATRY EXTENSION CLINIC IN A RURAL AREA

INSTITUTIONS
1. KMC Manipal, Psychiatry, Manipal, India
2. UCMS & GTB HOSPITAL, PSYCHIATRY, DELHI, India

AUTHORS
1. Vishal Chhabra¹, Dr., DPM, DNB (PSYCHIATRY, drvishal2010@yahoo.com
2. Podila S. V. N Sharma¹, Dr., DPM, MD, psvn.sharma@manipal.edu

AIMS AND OBJECTIVES: 1. To study and compare the sociodemographic, clinical, general health, functional level, quality of life, economic burden, family burden and psychiatry service satisfaction in two outpatient psychiatric clinic populations, one in a university-based General hospital (tertiary centre) and the other in a rural extension clinic (primary centre). 2. To elucidate any possible advantages/disadvantages of psychiatry outpatient services in the two settings mentioned above.

METHODS: Patients attending OPD at the two centers were taken up for the study using randomization. Seven different scales including WHO QOL BREF, DUKE health profile, GAF and CGI (S) were administered to assess various clinical, QOL, illness burden and service parameters.

RESULTS: Results show that the rural patients are older (p = 0.006), more severely ill (p= 0.003) having longer duration of illness (p = 0.001) compared to tertiary centre. Also they have lower level of functioning (p=0.001), poorer QOL (p= 0.015), poorer general and mental health and the families are more burdened with illness (p = 0.001) than their counterparts visiting tertiary centre. Interestingly, the same level of quality of care, is being perceived by both patient populations. But the accessibility is better (p= 0.001) and waiting period (p = 0.001) is less for rural centre patients. Rough cost estimates show that besides low operating costs, extension clinic saves time and money of already overburdened rural patients.

CONCLUSION: Despite study’s limitations, it appears that rural patients benefit from the extension clinic. The poorer illness variables, increased burden and low operating costs favour the continuation of such extension clinics.

4. Cristinel Stefanescu², DR., MD, cristinel.stefanescu@gmail.com

In our modern society more and more people are suffering from the daily stress that by time leads to hypnotic disturbances. Improving sleep quality prevents developing other co-morbidities, maintaining the mental health of population. With the help of this information, we considered realizing an observatory study on 60 people suffering from insomnia, with age 30-70 from Iasi, Romania. The objectives of our study were: 1. identifying insomnia interference with social and professional life; 2. underlying the risk factors for developing insomnia; 3. improvement of symptoms after education and sleep hygiene practice; 4. identifying psychiatric co-morbidities.

Method: Our data were obtained corroborating information from the clinic interview and the one from the sleep diary that each person has fill it in during a two weeks.

The results have shown the followings: the feminine population is 1.5 times more frequent affected by insomnia then men; from them 75% have reported the coexistence of disturbing sleep behaviors of their partners (snoring, alcohol use, etc). 83.3% of them admitted chronic consume of caffeine during afternoon. 6.6% have had a psychiatric diagnostic and 85% admits watching TV or reading or even just talking to their partner while in bed. Sleep hygiene program, which was accepted by 98.3% of participants has shown an increase of life quality.

Conclusion: More researches are required considering insomnia, so that the risk factors that determine it can be better identified.

7. Dimitra Lagou¹, Mrs, ssdnii@otenet.gr
8. Vasiliki Basogianni¹, Mrs, ssdnii@otenet.gr

Objectives
The Counselling Center provides drug abuse prevention services which promote mental health, and are part of broader health education. In this context, parent groups are carried out to support parents in their parental and conjugal role by the empowerment of their personal and social skills, and to enable them form opinions and attitudes that facilitate family relationships.

Method Each group consists of 8 to 10 parents, includes 8 to 10 two hours weekly meetings, is co-ordinated by one or two specialists, and parents have the opportunity to express thoughts, exchange views and share their difficulties in raising children.

Results Parents are encouraged to share their fears and anxiety, acquire better awareness of themselves and others, handle effectively relations with their children and improve communicative skills. The topics concerning the emotional development of children, communication in the family, relationships among parents, children and siblings, expression and understanding of emotions, and the handling of difficult situations are elaborated in the group by the use of experiential techniques. The meetings include also information on addictive substances and clarification of myths around drugs.

Conclusion Family is related with many protective factors (strong bonds, care and support, boundaries) and with risk factors (chaotic family environment, inadequate parental role, indifferent upbringing), which are connected with drug use and vulnerability to psychopathology. The change of parents’ attitude through experiential learning, which is promoted by the use of a group-centered model, can be effective in the process of prevention within the framework of broader programmes.

5. Goro Tanaka5, OTR, PhD
6. Yasuyuki Ohta6, Dr., PhD

Objective: To investigate occupational stress in relation to changes in the mental health of employed Japanese males over a 1-year period.

Methods: Subjects were 366 males employed at a manufacturing company in Nagasaki Prefecture. The study was conducted from August to October of 2005 and 2006. In both years, the mental health of all subjects was evaluated using the General Health Questionnaire 12 (GHQ-12). Deteriorated mental health was defined as a total GHQ-12 score of 4 or higher. Changes in mental health one year after the initial test were classified into the following four types: “maintained health,” “improved health,” “exacerbated health” and “continued poor health.” Furthermore, the Brief Job Stress Questionnaire was used to simultaneously assess job stressors, psychological stress reactions, and modifiers (job support, spousal support, job satisfaction, and family satisfaction). Consent to participate was obtained after subjects received an explanation of the study objective and methods. For statistical analysis, the four types were compared in relation to time and job stress scores using X2 tests.

Results: For the improved health group, job stressors, stress reactions, and modifiers generally improved. For the exacerbated health group, job stressors and psychological stress reactions exacerbated, and in particular, changes in modifiers increased stress. For the maintained health group, job support was adequate; however, for the continued poor health group, spousal support was lacking, thus elevating psychological stress.

Conclusion: Changes in the mental health of employed Japanese males were ascertained over a one-year period, and changes in modifiers appear to influence occupational stress.

Barriers to Integration of Mental Health with Primary Care in India

Institutions
1. The University of Western Australia, School of Psychiatry and Clinical Neurosciences, Fremantle, Australia

Authors
1. Mohan Isaac1, Professor, MD, DPM, FRCPsych, Mohan.Isaac@uwa.edu.au

Background: Mental health care is a grossly neglected area in India due to a variety of factors including acute shortage of trained mental health professionals. The objective of the National Mental Health Programme in India is to ensure availability and accessibility of minimum mental health care for all in the foreseeable future. One of the important strategies of the programme currently being implemented all over the country is integration of mental health care with existing health services by providing appropriate task oriented training to the primary care staff.

Objectives: As part of a larger review of the progress of implementation of the National Mental Health Programme, the “training in mental health” for different categories of health care personnel was audited

Methods: Training related data was obtained from 21 states through a mail questionnaire survey. During the site visits to all the centres carried out as part of the larger review, in-depth interviews of state level programme officers were carried out using a semi-structured schedule.

Results: Although the programme was adequately funded, only a minority of centres could train the targeted numbers of staff. Most centres could not carry out any follow up after the initial training. No meaningful continued “on-the-job” training or refresher programmes could be organized. A wide variety of impediments and bottlenecks for the successful implementation of the programme were identified.

Conclusion: There is a need to review and modify the content, curriculum and delivery of mental health training of primary care personnel in India.

PARTICULARITIES OF DISTRESS EXPRESSION AMONG MEDICAL UNIVERSITY STUDENTS

INSTITUTIONS
1. KazNMU, Psychiatry, Almaty, Kazakhstan

AUTHORS
1. Natalia Ivantchenko, Mrs., MD, natalia21.ca@yahoo.ca

Actuality Present days education in medical schools represents a complicated, dynamic process, including high level mental strain, time shortage, information overloading, strong control and planned timetable. Important component of specialist’s preparation have to be: timely diagnostics of neurotic and adaptation disorders among students on different levels of education.

Aim of research: Study psychiatric dysfunctions among students on different levels of education in order to develop a program of preventative help.

Study objectives:
1. Conduct a research of psychiatric dysfunctions among medical school’s students.
2. Verify reliability degree of SCL-90-R and possibility of using it in practice by mental health specialists in Kazakhstan.
3. Study revealed groups with different level of psychiatric dysfunctions.
4. Find out risk factors that influence development of psychiatric dysfunctions.
5. Develop a program of specialized preventive help for students on different levels of education.

Study material: By complete sampling were studied 300 Kazakh National Medical University students, 110 men and 190 women, average age 23.

Results: On this part of study the first and the second study objectives have been completed. Statistical analysis of SCL-90-R determined left side (positive) distribution asymmetry, what corresponded to the prevalance of negative responds on the questions of the psychopathology existence. Average results PSDI index corresponded to 1,05 (±)0,24.

Conclusion: Assuming dispositional stile of distress expression among students, it is necessary to complete this research with more questionnaires, clinical and psychopathological study.

1. Bozica M Ivic, Dr, MD, vladas@bankerinter.net

Nowadays sociotherapy does not treat only patients with mental disorders but it also comes more and more into so-called healthy layers of a society in which a mental patient lives. Every rehabilitation method, and so the sociotherapeutic one, does not rehabilitate only the part of a patient personality which is ill, but it tends maximally to engage also his/her remaining healthy power. The aim of a modern stationary hospital is not to tread a patient at hospital, but first of all to return him back to a society. Psychiatric stationary hospitals change their structure, sociotherapeutic teams are made, mental patients undertake their responsibilities, they do their social obligations, i.e. elements and customs from the life, which are valid in a healthy society, go into a psychiatric hospital. The aim is a gradually solving the appearance of ”hospitalism” or “asylum syndrome” and to introduce an “open door” system. Releasing symptoms of a disease is only the first sign of a therapy, while the final task is a complete reintegration of patients with mental disorders into small and wide social community, what can be achieved by well-planned and organized sociotherapy.

WHICH COMPONENTS OF CARE ARE IMPORTANT FOR RECOVERY OF LONG TERM MENTALLY ILL PATIENTS?
PROJECT DEMO.B.INC, RESULTS IN THE CZECH REPUBLIC

INSTITUTIONS
1. Psychiatric Department of the 1st Faculty of Medicine, Charles University, Prague, Czech Republic
2. St George’s University of London, London, United Kingdom
3. University College London, London, United Kingdom

AUTHORS
1. L. Kalisova

4. P. Turton
5. S. White
6. H. Killaspy

Aims: This presentation describes part of the first phase of the pan-European DEMoB.inc project (Development of a European Measure of Best Practice for People with Long Term Mental Illness in Institutional Care) which aims to develop a toolkit for the assessment of the quality of care, treatment, living conditions and human rights of people living in psychiatric institutions in Europe. As part of this project, a Delphi exercise was carried out in each of ten countries to assist in identifying the most important domains of care for inclusion in the toolkit.

Methods: Delphi exercises were carried out with 10-15 members of four expert groups (service users, mental health professionals, carers and advocates). Participants were chosen to represent a range of experiences, expertise and perspectives. All groups were asked to consider the most important factors which promote recovery for people with long term mental health problems residing in institutions of various kinds (hospital wards, community based settings). Respondents’ views were collated through three rounds of the Delphi exercise. Responses were obtained through post or email.

Results: Presentation of details of respondents, overview of the domains and specific items that were identified as being most important to recovery in the Czech Republic.

Conclusion: The overview of components of care which were considered to be important for recovery by respondents in the Czech Republic Delphi exercise is presented. Results are undoubtedly influenced by a development of psychiatric care in the Czech Republic and also by social, political and cultural context of the country.

TRANSPERSONAL APPROACH TO HEROIN ADDICTION

INSTITUTIONS
1. medical centre of doctor Nazaraliev, Bishkek, Kyrgyzstan

AUTHORS
1. Jenishbek Nazaraliev, Dr., MD
2. Viacheslav Karagapolov, Mr.

An increased frequency in depression, anxious and psychosomatic disorders, spread of chemical and non chemical addictions are the primal indicators which evidently prove serious inner disagreements and problems of the humans and mankind in general. Such problems often hard to solve in the normal state of consciousness, which in many cases causes alcohol or drug abuse and experiments with psychoactive substances; yet, they can be solved during transcendental or a transpersonal experiences, which can be attained during specially developed spiritual practices and psycho trainings. Our program “The 7th sky” includes a complex of meditative psycho techniques based on the integral yoga by Shri Aurobindo; the ”Dervish Dance”, based on the ancient Sufi ritual; a group mantra chanting ’AUM’; psycho - hygienic training called Lapidopsychotherapy, in which we used a stones as an transfer objects; relaxation training and the Vow of Silence for 48 hours. These, very well arranged techniques provide maximally positive results in the process of very intensive, short term therapy. The objective of the 7th sky is the achievement of psycho energetic personality transformation, mental rehabilitation, self discovery, discovery of inner potential resources and discovery of creative abilities.

Results of psychological testing of 150 patients with heroin addiction shows increased levels of self-integration (ideal and real self-conception), improvements in cognitive sphere. That proves a good potential of the program used in the complex addiction therapies.

Objective: To study peculiarities of psychopathological manifestations of irritable bowel syndrome (IBS) depending on character of functional disturbances in patients with neurotic and affective disorders.

Methods: In Borderline States Department we examined 72 patients (52 female and 20 male; 44.28±5.32 years) with IBS previously observed by gastroenterologist without effect from somatotropic therapy. We used clinical-psychopathological, experimental-psychological methods of investigation. Diagnosis of IBS was made according to Roman Criteria II.

Results: We revealed clinical-psychopathological peculiarities of IBS in patients depending on current mental state and character of functional disturbances of gastrointestinal tract. 35 patients (48.61%) with affective disorders (depressive episode of mild degree was observed in 15 patients, middle degree in 12, severe - in 8).

Comorbidity of depressive symptoms and IBS was characterized by constipations, abdomenaligas that were notable for monotony, uniformity, and uncertainty of pain sensations. 23 (31.94%) patients were diagnosed as having neurotic, stress-related and somatoform disorders (anxious-phobic in 8 persons, adjustment disorders according to type of reaction to stress in 12, mixed anxious and depressive disorder in 3). Disturbances of function of intestine manifested by migrating pain syndrome, flatulence, and diarrhea combined with negative symptoms. In 7 patients (19.45%) hypochondriac symptoms (senestopathic, cancerphobic, cardiophobic, and conversion symptoms) prevailed. In 60% of cases, clinical symptoms of IBS are connected with psychotraumatic situation. Polymorphism of mental disturbances associated with disturbances of thick intestine, persistent psychological disadaptation of patients predetermines obligatory interaction of specialists of therapeutic and psychiatric profile for treatment and rehabilitation of IBS patients.

RELATIONSHIP BETWEEN TEMPERAMENT, EFFECT OF PAST TRAUMA AND CURRENT STATUS OF ANXIETY IN SOUTH KOREAN FIRE OFFICERS: PRELIMINARY STUDY

INSTITUTIONS
1. Keyo hospital, Psychiatry, Uiwang, Republic of Korea
2. Saint Andrew’s Neuropsychiatric Hospital, Psychiatry, Icheon, Republic of Korea

AUTHORS
1. Eung-Jo Kim, Dr, MD, empathykim@hanmail.net
2. Joo-Eon Park, Dr, MD
3. Seok Jun Park, Dr, MD, parksjnp@naver.com
4. Kyehyun Hong, Dr, MD, keyhyunni@hotmail.com

Aims The objective of this study was to evaluate correlation among temperament, character, current effect of past trauma, and current status of anxiety in fire officers in South Korea.

Methods A total of 43 professional fire officers was included in the study. (Mean age 37.95±7.07 years) For the effect of past trauma and current anxiety status, we used the Impact of Event Scale - Revised (IES-R), State-Trait Anxiety Inventory (STAI), and Beck depression inventory (BDI). Indeed, Korean version of Temperament and Character Inventory (TCI) was examined to evaluate temperament.

Results There was no difference in socioeconomic and educational background. There were unique correlations between novelty-seeking profiles of TCI and IES-R scores (r=0.345). Intrusions subscales (r=0.358) and hyperarousal subscales (r=0.443) of IES-R were also correlated with novelty-seeking. The character dimension was associated with STAI and BDI, especially self-directedness was most powerful profiles with STAI, both state-anxiety(r= -0.613) and trait-anxiety(r= -0.713). BDI was related with harm-avoidance, persistence profiles of temperament dimension and self-directedness, self-transcendence profiles of character dimension.

Conclusions This preliminary data suggest that novelty-seeking behaviors may be one of risk factors for posttraumatic stress symptoms. Self-directedness profile of character dimensions could represent a strong influence on current anxiety and depressive symptoms, although other temperament and character profiles might give effect of current mood symptoms.

2. T.Y. Hwang¹, Mr, MD,PhD
3. Y.S. Choi², Mrs
4. E.K. Kim³

Objectives: To evaluate clinical and economic benefit from the public services of community mental health center.

Methods: Subjects for clinical analysis were 159 clients who entered rehabilitation programs of community mental health center of Yongin city. Global Assessment of Functioning Scale (GAF) and Brief Psychiatric Rating Scale (BPRS) were checked at entry and every six months during the first 30 months. Subjects for cost-benefit analysis were 99 clients who entered the rehabilitation programs of the same community mental health center. Cost-benefit from the rehabilitation services of community mental health center during the first 2 years was calculated by several variables such as invested budget, changes of mean length of hospitalization and monthly earned incomes, etc.

Results: Mean GAF score was elevated from 52.97 to 54.77 during the first 12 months. But the changes during the total 30 months were not significant. Changes of BPRS score were not statistically significant. Calculated cost benefit was 183 percent of invested public budget after 1 year, and it was elevated to 405 percent of the invested budget after 2 year. And both results were statistically significant.

Conclusions: Rehabilitation services of community mental health center are economically beneficial.

CARICATURE AND PSYCHOANALYSIS

INSTITUTIONS
1. Istanbul Commerce University, Psychology, Istanbul, Turkey
2. Istanbul University, Psychology, Istanbul, Turkey

AUTHORS
1. Esra Kirez¹, Ms, esrakirez@yahoo.com
2. Busra Tanık², Ms, busra_tanik@hotmail.com

AIMS Psychoanalysis is a well-known and has been rapidly outspreaded theory in Psychology and Psychiatry theories. The only instrument of Psychoanalysis is language. Jokes, lapses and indirect speeches are very important in this theory. From that point, the usage of Psychoanalytic terms in daily life from its' prevalence in humour in Turkey was searched in this study.

METHODOLOGY A descriptive research was done and the humour magazines which were published between 1980-2005 was scanned. This journals are Girgir, Leman and Penguen 546 of Girgir, 404 of Leman and 165 of Penguen was scanned.

THE RESULTS At the end of the scanning, 245 caricature which has psychoanalytic terms was found. The data was assessed by putting them in some special categories. These categories are; Psychology, Psychoanalysis, Psychologist and Psychiatrist, Getting back to uterus and the trauma of birth, Getting back to childhood, Drive, Unconscious and Conscious, The conflict of Oedipus, Theorists, Association, The Phases of Development, Neurosis, Couch, Libido, Hypnosis, and Ego. The usage of Psychoanalytic terms in humour was found as very common. However, the another finding of our research is the each of the terms which belongs to Psychoanalytic theory are sometimes lossing their original meaning in daily life speeches.

METAHABILITATION: A TRANSPERSONAL AND SPIRITUAL APPROACH TO PTSD

INSTITUTIONS
1. Institute of Transpersonal Psychology, Center for Trauma Studies, Palo Alto, CA 94303, United States

AUTHORS
1. Patrick Marius Koga¹, Dr., MD, MPH, mkoga@itp.edu

Aims/Objectives: Traditional psychiatric rehabilitation programs for PTSD in war refugees and military veterans are built almost exclusively and fallaciously on the etic, biomedical understanding of mental crisis. Important factors of illness such as spirituality, self-concept, self-motivation, perceived benefits, and self-transformation have been neglected with negative consequences for the therapeutic outcomes [1]. This workshop proposes a paradigm shift in the theory and practice of trauma rehabilitation by integrating the emic side of patient’s experience and calling for a higher metamorphosis of the fragmented old self-concept.

Methods: The workshop introduces the participants to a novel transpersonal model of psychosocial rehabilitation: Metahabilitation. Organizing constructs: Reuben Hill’s ABC->X Theory, Health Belief Model, Transtheoretical Model of Change, Theory of Reasoned Action, Theory of Planned Behavior; Roy’s Adaptation Model, Behavioral Activation Therapy, Narrative Constructivist Therapy, Campbell’s Hero’s Journey, Mindfulness.

Results: The workshop will present the brain neuro-network of fear and survival, the neurophysiological correlates of spiritual unitive experiences; religious modulators of PTSD including healthy and unhealthy religious value orientation, spiritual assessment instruments like SAI, FICA, and HOPE, and the integration of transformative spirituality in the overall PTSD treatment.

Conclusion: Workshop participants will be able to use the Metahabilitation model in their clinical work with civilian and military patients traumatized by war or terrorism.

4. Bela Shah², Dr., MD
5. Shanti Nambi³
6. Sarvada C Tiwari⁴
7. Chandra Bhushan Tripathi⁵
8. Ravinder Singh⁶
9. Sarbjeet Khurana⁷

Objectives: To assess the average service load in different sectors of tertiary specialist mental health services and primary care general health services.

Methods: Comprehensive mapping of the specialized mental health services in 3 cities was carried out in order to get a panoramic view of the existing situation, understanding of the pattern of utilization of services and mapping of all general health services at the primary care level, as well as the average mental health service load, in terms of the estimated proportion of the cases with psychiatric disorders, from amongst the newly registered cases. The latter was extrapolated to the population for the entire city. The research activities were carried out in 3 cities in identical fashion, with uniform tools and methods.

Results: Analysis of average monthly service load in specialist mental health services across the sectors revealed the government sector carrying nearly 2/3rd of the service load in two of the three cities. The service load in the non-governmental organizations (NGO) sector was found to be uniformly low across the sites. The government sector carried a relatively small proportion of service load in the primary care general health services; wherein the private sector was carrying a large proportion of the service load (40-60%). The non-formal sector providers carried about 1/3rd of the service load.

Conclusion: The findings have important implications for policy planning in urban areas in terms of reorganization of various sectors for making the mental health services more equitable with regards the average service load.
P-04-098
THE ROLE OF CRISIS RESOLUTION SERVICES IN THE SECONDARY PREVENTION OF PSYCHOSES

INSTITUTIONS
1. Royal Free Hospital, Department of Psychiatry, London, United Kingdom

AUTHORS
1. Massimo Lanzaro, Dr, MD, massimo.lanzaro@royalfree.nhs.uk

The work to improve the secondary prevention of psychoses has mainly two aims: to find strategies for earlier detection and to develop treatment methods and programs that are tailor-made for patients in the early phases of schizophrenia. Recent investigation of duration of untreated psychosis (DUP) has demonstrated that although individuals generally receive treatment within 6 months of symptom onset, others remain untreated in the community for 1-2 years (Birchwood et al., 2002). Understanding the service impediments to early detection may be an essential prerequisite for attempts to reduce these potentially deleterious treatment delays. In the UK most Early Intervention Services are unable to provide true secondary prevention, but only, at present, to treat people in the midst of their first major episode such that they have a decreased progression of the illness. We have noticed some encouraging preliminary results with the intensive home-treatment team (CRHT), and noticed unexpected potentials of this part of the Services for true secondary detection and intervention for people in the prodromal stages of psychosis. There are wide variations between regions and Trusts with different resource levels and different planning. Nonetheless an interesting, preliminary, recent study in the London boroughs of Camden supports the hypothesis of crisis resolution teams as “earlier than early” intervention services, also highlighting the clinical implications in averting admissions and achieving a pragmatic balance of community and hospital care. The author suggests that this may be a new and challenging topic of research in the field of prevention and pathways to care.

A STUDY ON THE SERVICE PRIORITY AND STANDARD PERFORMANCE OF COMMUNITY MENTAL HEALTH CENTERS IN KOREA

INSTITUTIONS
1. Seoul Metropolitan Mental Health Center, psychiatry, Seoul, Republic of Korea
2. Yong-In mental hospital, psychiatry, Yong-In city, Republic of Korea
3. Ajou University, Social medicine, Suwon, Republic of Korea

AUTHORS
1. Myungsoo Lee, Dr, MD, MPH, mslee1010@gmail.com
2. Taeyeon Hwang, Dr, MD,PhD, lilymh@dreamwiz.com
3. Youngmoon Lee, Dr, MD,MPH, humanishope@hanmail.net

In Korea, community mental health center (CMHC) is an important infrastructure of national mental health service system. Although everyone can agree with the importance of CMHC as a key unit of national mental health system, there are many debates about what and how the CMHC should do. The objective of this study was to define service priority and standard performances of CMHC. This study was carried out by the Delphi - method. Forty experts of community mental health were participated in this study.

The major results are as follows:
1) Based on a general increase and strengthening the quality of mental health services to serious mental illness, we can expand to other candidates such as child & adolescent, depression, aged people and so on with rational priority setting process.
2) Standard performance of CMHC

- screening and primary mental health services for early psychosis, child & adolescent, depressed people and aged persons
- specialized mental health services for the serious mentally ill people, depressed people, child and adolescent
- education and consultation for the serious mental illness, child and adolescent, depression and suicide high risk group
- crisis intervention for the high risk group of suicide and serious mental illness
- public relations and community organization for the reintegration of mental illness into society

We expect these results can be applied to national mental health service guideline for the standardization of community mental health centers.

REINTEGRATING PSYCHIATRIC PATIENTS TO FAMILY PRACTICE CARE

INSTITUTIONS
1. Institute of Mental Health, General Psychiatry, Singapore

AUTHORS
1. Nelson B C Lee, Dr, nelson_lee@imh.com.sg
2. Rebecca K S Chong, Ms

Aim: To re-integrate patients from a tertiary psychiatric hospital, the Institute of Mental Health (Singapore), to family practitioners in Singapore who traditionally do not see psychiatric patients with serious mental disorders in their clinics.

Methods: Family practitioners were contacted and doctors keen to do so were given a refresher course on psychiatric care. There were also given sessions to sit in with Consultant Psychiatrists to hone their skills and enrolled into the partnership programme subsequently. Careful selection criteria for stabilised patients were established for referral. Close support was provided for both patients and doctors with 24 hour help lines available for both groups. A survey was conducted at the end of the first year to establish the overall satisfaction of both parties. Satisfaction ratings were based on a 4 point scale of excellent, good, fair and needs improvement.

Results: Ratings of good or excellent were above 70% for almost all the criteria rated for. These included ratings of coordination of care, availability of assistance of the case manager and liaison coordinator and overall satisfaction with the delivery of the programme.

Conclusion: This is the first time a programme has been established in Singapore where traditionally Family Practitioners do not follow up psychiatric patients with serious mental disorders. The success of the programme is encouraging and has been adopted at the Ministry level to embark on a larger scale programme to the rest of the country as part of the initiatives of the National Mental Health Blueprint.

THE IMPACT OF DEPRESSION ON THE HEALTH RELATED QUALITY OF LIFE IN KOREAN PATIENTS WITH CARDIOVASCULAR DISEASE

INSTITUTIONS
1. Wookwang University School of Medicine, Psychiatry and Behavioral Medicine, Iksan, Republic of Korea
2. Wookwang University Graduate School, Public Health, Iksan, Republic of Korea

AUTHORS
1. Sang-Yeol Lee, Professor, MD,PhD, psysangyeol@hanmail.net
2. Jin-Ho Cho
3. An-Sook Na

Objectives: The aim of this study were to evaluate psychosomatic characteristics and quality of life (QOL) in patients with cardiovascular disease and to examine the impact of depression on the health related quality of life in Korean patients with cardiovascular disease.

Methods: We enrolled 149 patients with cardiovascular disease from Wookwang University Hospital and divided into two groups according to the subscale of Depression in Personality Assessment Inventory (PAI). We compared anxiety, aggression and health related quality of life between depressed and non-depressed group. Anxiety and aggression were measured by the PAI scale and quality of life (QOL) was measured by Short-Form 36 Health Survey-Korean Version(SF-36-K).

Results: The baseline clinical cardiovascular characteristics were not different between the two groups. The prevalence of anxiety, aggression, depression were 17.4%, 13.4% and 28.9%. Anxiety was significantly higher in depression group than in non-depression group. Health related quality of lifes were significantly decreased in related to depression and severity of depression. A correlation analysis showed that health related quality of lifes were significantly negative correlated depression.

Conclusions: This study showed that the prevalence of depression in Korean cardiovascular disease patients might be high. The health related quality of life of patients with cardiovascular disease is significantly decreased in depression group. There was a negative relationship between depression and health related quality of life in patient with cardiovascular disease. The psychosomatic intervention will be needed in these patients.
THE QUALITY OF LIFE IN PEOPLE WITH MENTAL ILLNESS WHO ATTENDED COMMUNITY MENTAL HEALTH PROGRAMS

INSTITUTIONS
1. YONGIN MENTAL HOSPITAL, PSYCHIATRY, YONGIN CITY, Republic of Korea
2. HWASEONG CMHC, SOCIAL WORK, HWASEONG CITY, Republic of Korea

AUTHORS
1. Jonggook Lee¹, Dr, MD, leejg62@dreamwiz.com
2. Gyu-Dong Seo², Mr, MSW

Aims: This study was conducted to investigate the current status of the QoL in people with mental illness who attended community mental health services. The authors also intended to identify the factors associated with the QoL.

Methods: The subjects were 1400 persons with mental illness who attended the community mental health programs of Gyeonggi province in Korea. Assessment tool of QoL was WHOQOL-BREF. The authors used descriptive analysis and analysed the data with Pearson’s correlation, and multiple regression.

Results: Mean score of overall QoL was 5.90 out of 10.0. Overall QoL was related with age(r=-0.090, p<0.01), marital status(r=-0.111, p<0.01; single>married), duration of attendance(r=0.067, p<0.05). Physical health was related with age(r=-0.114, p<0.01), education level(r=0.127, p<0.01), marital status(r=-0.149, p<0.01). Psychological status was related with age(r=-0.100, p<0.01), education level(r=0.107, p<0.01), marital status(r=-0.141, p<0.01). Social relationships domain was related with age(r=-0.064, p<0.05), marital status(r=-0.087, p<0.01). Environment domain was related with age(r=-0.115, p<0.01), education level(r=0.162, p<0.01), marital status(r=0.136, p<0.01).

Conclusions: The quality of life in people with mental illness who attended community mental health programs in Korea showed moderate level. It was associated with age (young>old), education level(high>low), marital status(single>married), duration of attendance(long>short). The results of this study will be used as a baseline data when assessing the effectiveness of the community mental health services.

MENTAL HEALTH OF BRAZILIAN YOUTH ON THE STREETS

INSTITUTIONS
1. Federal University of Rio de Janeiro - Brazil, Psychiatric Institute, Rio de Janeiro, Brazil

AUTHORS
1. Ligia C. Leite¹, Dr., PhD, ligialeite@invenciveis.com
2. Adriana P. Botelho¹, Mrs, Psychologist, adrianabotelhopsi@gmail.com
3. Joana I. Carinhanga¹, Mrs, Psychiatric nursing, iabrudi@yahoo.com

Objective: The purpose is to explore the hypothesis that “the choice” for the streets is a search for mental health by Brazilian poor children.

Method: Analyze the history of a 17-year-old male exemplifies aspects of his mental health, psychological suffering and social risks experienced by the disaffiliated youth. The material was collected through field diary entries and patient registry. Field of study was set on the Psychiatry Institute of the Federal University of Rio de Janeiro, in 2006, within the research project School evasion, drugs, and criminality: the byways of adolescence.

Results: The narratives of this case study bring an important asset to reveal this young man’s subjectivity through his own voice. It was possible to verify the constant search for mental health on the streets to escape from psychological suffering in the family. Otherwise, the social risks are present in the lack of public polices. Work in psychosocial rehabilitation can be an important therapeutic strategy for the social reafiliation.

Conclusions: The different forms of “invisible” violence - such as the random assignment of the children by the shelters, and the lack of: family living, recognition of rights and mental health policies coverage - results in the increase of social violence. The streets, differently, are not only a place of transit, but a way of life, a survival space, a possibility to create bonds and find mental health, even though the abducted and analysed narratives show us the psychological suffering and social risks.

PARALLEL TRADE AND PUBLIC HEALTH: RISKS TO VULNERABLE PATIENT POPULATIONS

INSTITUTIONS
1. University of California San Diego School of Medicine, San Diego Center for Patient Safety, San Diego, United States
2. California Western School of Law, Institute of Health Law Studies, San Diego, United States
3. San Diego State University, Graduate School of Public Health, San Diego, United States

AUTHORS
1. Bryan A. Liang1,2,3, Professor, MD, PhD, JD, baliang@alum.mit.edu

Background: The European Commission has identified safety issues associated with parallel trade in pharmaceuticals.

Methods: Assessment of parallel trade rules and counterfeit drug incidence in the EU and means to protect the populace from fake drugs.

Results: Parallel trade, particularly through the Internet, has allowed virtually unfettered patient access to drugs without provider oversight and criminal element introducing fake drugs into the drug supply. Legal efforts have had limited success in stemming this result. Both create dangers to vulnerable patient populations, particularly mental health patients who may obtain excessive amounts of drugs or be left completely untreated.

Conclusion: Vulnerable patient populations are at risk under the current system of parallel trade and the Internet. Mental health professionals must educate patients and be aware of the risks associated with the current infrastructure of drug access.

DESCRIPTIVE STUDY OF THE BASELINE CHARACTERISTICS OF PATIENTS FROM THE COMMUNITY MENTAL HEALTH TEAM (CMHT), SINGAPORE

INSTITUTIONS
1. Institute of Mental Health, Community Psychiatry, Singapore, Singapore

AUTHORS
1. Boon-Leng Lim1, Dr, boon_leng_lim@imh.com.sg
2. Alvin Liew1, Dr
3. Cheng Lee1, Dr

Aim: This cross-sectional study examined the baseline characteristics of patients from CMHT. The differences between the two groups of the program, Assertive Care Management (ACM) vs Standard Care Management (SCM), were highlighted.

Method: A total of 82 patients participated in this study. Patients' demographics and baseline measurements such as Brief Psychiatric Rating Scale (BPRS), Global assessment of Function (GAF), Life Skills Profile (LSP) and WHOQOL-Bref were collected.

Results: There were 41 patients in each group. In total, 78.0% were Chinese, 11.0% Malays and 11.0% Indians. 40.2% were males. Mean age was 44.2 (SD=10.0). Schizophrenia (74.4%), Schizoaffective disorder (6.1%) and Bipolar Disorder (4.9%) accounted for 85.4% of the diagnoses. Between ACM & SCM, there was no significant difference in their baseline demographics, daily prescribed chlorpromazine-equivalent dose and BPRS score. Analysis of covariance controlling for age, diagnosis, gender, race, type of program (ACM vs SCM) and daily chlorpromazine-equivalent dose for baseline measurements showed the following: ACM patients had 1.12 (p<0.001) more admissions and 67.56 days (p<0.001) longer length of stay compared to SCM. ACM patients scored significantly better for the LSP Withdrawal (1.62, p=0.02) and self-care (0.96, p=0.03) subscale and the WHOQOL-Bref Psychological (8.39, p=0.01), Social Relationship (10.71, p=0.002) and Environment (8.39, p=0.01) subscales.

Conclusion: At baseline, ACM patients appear to have better psychosocial status and quality of life compared to their SCM counterparts despite a higher rate of hospitalization. This may be related to the help seeking behavior in the ACM group and may explain why they have better results from rehabilitation.

THE KNOWLEDGE FOR THE PROFESSION OF PSYCHIATRIST IN TIRANA

INSTITUTIONS
1. University Hospital Center "M. Teresa", Psychiatric Service, Tirana, Albania

AUTHORS
1. Pasho Maksuti¹, Dr., MD, pashomaksuti@yahoo.com
2. Anila Hashorva¹, Dr., MD, anilahashorva@yahoo.com

Objective: To investigate the level of knowledge for the profession of psychiatrist in Tirana city.

Methods: We designed a questionnaire about the knowledge for the profession of psychiatrist. 324 persons of different social and educational levels from different squares of Tirana completed the questionnaire. They answered in a written way to this questionnaire.

Results: We found that 64.5 % of them know that psychiatrists are medically qualified, 32.1 % of them that the psychiatrist is necessary less than 10 years to be trained. 55.5 % of people say that the psychiatrist and the psychologist are the same; 39.4 % say that the neurologist and the psychiatrist are the same and 30.5 % say that the psychiatrists and social workers are the same profession. 44.3 % didn’t know that psychiatrists use tablets, 37.8 % didn’t know that psychiatrists use injections and 74.8 % didn’t know that psychiatrists use electroconvulsive therapy. 65.1 % say that the psychiatrists use counseling, 39.5 % of persons didn’t know that the psychiatrists treat the mental disorders, 58.7 % say that they will go to the psychiatrist with the recommendation of general practitioner, 43.5 % by the recommendation of the relatives, 26.7 % by the judge, 31.2 % by the police and 50.0 % by themselves. 41.2% first will go to the cleric for mental problems.

Conclusion: Our finding suggests that it is necessary to do more for right information about the role of psychiatrist and mental health.

RECOVERY AND PROGRESS CLINIC ; A PILOT STUDY IN THE REALM OF NEW WAYS OF WORKING IN GENERAL ADULT PSYCHIATRY

INSTITUTIONS
1. Mersey Care NHS Trust, Psychiatry, Liverpool, United Kingdom

AUTHORS
1. Masood Malik¹, Dr, drmasoodmalik@msn.com
2. Simon Tavernor¹, Dr

AIM: To develop a new RAP (Recovery And Progress) Clinic to facilitate the transfer of care from secondary to primary care of the patients identified by a consultant attitude survey deemed suitable for management in general practice

METHOD: An initial audit conducted in the north west of England identified out of the potential 260 patients that 42 (17%) could be managed in primary care. 20 pts selected out of the 42. An invitation letter developed by service user and management group invited them to the RAP clinic. A literature search was conducted to develop the theoretical framework for the RAP clinic sessions. 8 Sessions each 1 hour long and 1 month apart developed.( Session 1 attitudes, 2 goals, 3 relapse indicators, 4 protective, 5 recap, 6 close confidant, 7 joint gp. 8 formal discharge )

RESULTS: 5 Consultants and 1 staff grade interviewed about out patient clinics and 260 pts considered in total 42 identified for ongoing management by gp 20 selected to enter RAP clinic 16 Refused and preferred immediate automatic discharge to GP 4 engaged

CONCLUSION: Small sample size due to reluctance to actually engage in the RAP clinic which demonstrates the challenges of this pt group. RAP clinic framework promotes recovery model of mental health. The pts who engaged found it useful and the GP’s were very engaging in joint assessments as it aided discharge preparation and continuation of care.

India until recently was considered to be a conservative and culture bound country. This perception is fast changing and we are emerging as one of the fastest developing nations. This progress and change has also reached our adolescents, who are at the crossroads which lead to a lot of confusion and problems to them and their elders. Blooming India is a community development initiative, sponsored by the Rotary club of Aarch City Madras - Rotary International District 3230, targeting the adolescent population of India. It is aimed at equipping the adolescent with the right tools to deal with these various distractions and upheavals he will face during the adolescent phase, which until now has not been emphasised in our country. We began by addressing 13 yr olds of grade 8 in various schools and educating them on the physical, emotional and psychological aspects of adolescence and education was imparted based on the prevailing local religious/cultural aspects. They were also educated about the right sources to approach in times of need. The teachers and parents were also addressed. We will also be covering the middle and older adolescents on the same parameters.

THE MAIN DIRECTIONS FOR REFORMING OF THE PSYCHIATRIC SERVICE IN UKRAINE

INSTITUTIONS
1. Institute of Neurology, Psychiatry and Narcology of the AMS of Ukraine, Kharkiv, Ukraine

AUTHORS
1. Petro V. Voloshyn, Prof., MD, PhD, inpn@ukr.net
2. Natalia O. Maruta, Prof., MD, PhD, akutikov@ukr.net

According to official statistical data 2.5% of populations of Ukraine need psychiatric care. Along with this it is occurred a growing of incidence of mental disorders (in 1.2 times per 100,000 during last 15 years). Among patients registered at psychiatric institutions 60.1% are patients of efficient age, 21.8% are children and adolescents. We register also an increasing amount of disabled patients (in 2 times as compared with 1990). Causes of such a situation are as follows:
- spreading of stigmatization;
- insufficient legal basis to regulate activities of the psychiatric service;
- poor integration of the psychiatric service into a primary medical-sanitary network;
- obsolete structural and functional organization of the psychiatric service;
- insufficiency of appropriate staffs (a poor involvement of medical psychologists, psychotherapists, social workers);
- insufficient financial support for this medical area and unreasonable schemes for usage of means.

In order to overcome the above mentioned causes the Conception of the State Object Complex Program for development of mental health in Ukraine for 2008-2012 was worked out on initiative of the Ministry of Health of Ukraine.

LIFE EVENTS, SOCIAL SUPPORT AND MENTAL HEALTH SERVICE USE IN BALTIMORE ECA COHORT

INSTITUTIONS
1. Johns Hopkins School of Public Health, Mental Health, Baltimore, United States

AUTHORS
1. Pallab K Maulik, Dr, MD, MSc, pmaulik@jhsph.edu
2. William W Eaton, Dr, PhD, weaton@jhsph.edu

Objective: The network-episode model provides a framework to understand mental health service (MHS) use. Current research on the effect of life events (LE) on MHS use is mostly cross-sectional. This study aims to find the association between specific LE experienced over the past year, and MHS use, given the type of social support (SS) available.

Method: The Baltimore Epidemiologic Catchment Area (ECA) study gathered mental health related information from a cohort of 3481 subjects over four waves between 1981-2005. For this study, data from the last two waves will be analyzed using a longitudinal (GEE) model to look for the association of different LE on MHS use. The direct and indirect effect of SS will be studied.

Results: Initial analysis showed that SS affected use of MHS following divorce. General health services use increased with number of relatives. Having >6 relatives compared to none was associated with more MHS use (OR=3.4, 95%CI 1.4, 8.2), after adjustments including depression. Being in touch with a friend for only a few times per week compared to daily, reduced psychiatric service use (adj OR 0.5, 95%CI 0.3, 0.9).

Conclusions: Accessing MHS following a divorce varied according to types of SS. The study will further analyze the effect of different LE on MHS use, allowing for the direct and indirect effects of SS.

THE ROLE OF MENTAL DISORDERS AS MEDIATORS IN THE PATHWAY BETWEEN LIFE EVENTS AND MENTAL HEALTH SERVICES USE

INSTITUTIONS
1. Johns Hopkins School of Public Health, Mental Health, Baltimore, United States

AUTHORS
1. Pallab K Maulik, Dr, MD, MSc, pmaulik@jhsph.edu
2. William W Eaton, Dr, PhD, weaton@jhsph.edu

Aims: The aim was to assess the role of common mental disorders as mediators, in the pathway between life-events and mental health services use in the Baltimore Epidemiologic Catchment Area Study.

Methods: Population-based data on mental health was gathered in 1993 and 2004. Data were analyzed to assess the effect of depression, generalized anxiety, panic, alcohol use disorders (as assessed by DSM III-R) and GHQ20 score >=4, as mediators, in the pathway between 8 different life-events experienced within the last year of the interview, and mental health service use within the last 6 months. Confounders were adjusted in multiple logistic regressions conducted for mediation analysis. All possible combinations of life-events, mental disorders and service use were analyzed.

Results: Depression and alcohol use disorders mediated the effect of life-threatening illness and use of mental health service use within general health setup. High GHQ scores mediated the effect of life-threatening illness and cumulative effect of all 8 life-events on accessing mental health services within a general health setup. High GHQ scores also acted as a mediator in the pathway between divorce/separation and cumulative effect of 8 life-events on psychiatric services use. Other combinations of life-events and services use, including informal services, were not mediated through any mental illness.

Conclusions: Generally use of mental health services is thought to be due to mental illness. The public health implications of using mental health services after a life-event without necessarily being mentally ill, as found here, is discussed.

3. Aleksandar Macic¹, Dr., filstem@cg.yu  
4. Jovan Kmzic², Dr.

The aim of this paper is to evaluate current treatment method for chronic psychiatric patients and to find an appropriate approach which is to be implemented by Mental Health Center.

Method used in this paper consists of comparative analysis between data obtained from psychological and psychiatric clinical assessment and data obtained from patients' treatment satisfactory level report. Research included 20 patients under case management treatment and 20 patients treated exclusively by traditional, institutionalized psychiatric method. Data were then processed with $X^2$ test.

The results show that there is no statistically significant difference in treatment satisfactory level reports between the two chronic patients groups. Regarding the psychological and psychiatric clinical assessment data, the results show statistically significant difference in these two groups and imply the advantage of Case management method regarding social involvement of these patients as well a reduction of hospitalism effect.

Conclusion: Case management program has more long term advantages in comparison to the institutionalized program due to better social involvement of beneficiaries and hospitalism effect reduction.

3. Ali Kamkar³, PHD

**Aims/Objectives:** Nomad populations in Iran, have hard living situation, but there is little research regarding the mental health of them (1, 2). This study investigated the prevalence of depression and anxiety in nomads versus villagers of Qashqai tribe.

**Methods:** 95 people of nomads from Ashori family of Qashqai tribe selected randomly as case group. Control group were 86 people of villagers from same family. Assessment tool were Hamilton anxiety rating scale and Beck depression rating scale. The results were analyzed using qui square test.

**Results:** The depression rate were 66% in nomads (29.5 % mild and 36.5 % moderate and severe), and 15.3% in villagers (8.2% mild and 7.1% moderate and severe). The difference is statistically significant. The anxiety rate in nomads were 56.8 % (38.9% mild and 17.9 % moderate and severe) and in villagers 12.7 % (7 % were mild and 5.7% were moderate and severe). This difference is statistically significant too. In both groups depression and anxiety rate were more in married, uneducated and female subjects than singles and males.

**Conclusions:** Depression and anxiety rates in nomads were more than those in villagers and these rates are higher than the national rates. These rates were more in married, females and in those with low education.

PSYCHOACTIVE SUBSTANCE USE AND HIV RISKY SEXUAL BEHAVIOUR AMONG STUDENTS OF THE UNIVERSITY OF MAIDUGURI BORNO STATE NORTH EASTERN NIGERIA

INSTITUTIONS
1. Federal Neuro Psychiatric Hospital, Mental Health, Maiduguri, Nigeria
2. Ahmadu Bello University teaching Hospital, Psychiatry, Zaria, Nigeria

AUTHORS
1. Abdulaziz Mohammed1, Dr, MD, zizo922000@yahoo.com
2. Said M Jidda2, Dr, MD, mohammedpsycho@yahoo.com
3. Omeiza Beida1, Dr, MD
4. Rabbebe B Isa1, Dr, MD
5. Taiwo Sheik2, Dr, MD
6. Abba Wakil1, Dr, MD

Aims and objective: To determine the prevalence of psychoactive substance use. To assess the interrelationship and socio demographic correlates of psychoactive substance use and HIV related sexual behaviors. To proffer recommendations on how to reduce psychoactive substance use and HIV related sexual behaviour

Methods: The study was cross sectional and multi stage sampling technique was used. The WHO student drug use questionnaire and UNAIDS general population survey module as modified was used for data collection. Strict confidentiality was ensured

Results: 230 students completed the questionnaire of which 200 was analysed. The mean age and standard deviation of respondents was 24.3 and 4.0 years respectively while 71% of them were males. The life time prevalence of psychoactive substance use was 56.6%. The most commonly used psychoactive substances were Alcohol (39.3%), Tobacco (25.0%), Cannabis (9.7). 49% of the students have had sexual experience. 41.2% and 38.5% of those who have had sex did not use a condom during the first and last sexual experience respectively. 38% of the students have multiple sexual partners. Alcohol use during last sexual experience was 12%. Male students were more likely to be using psychoactive substances (P<0.05). Students who were using psychoactive substances were more likely to have had sexual experience (P<0.001).

Conclusion: This study provided evidence of a link between psychoactive substance use and risky sexual behaviour among the students and underscores the importance of integrating psychoactive substance abuse prevention policies with that of HIV/AIDS in Nigeria. Psychiatrists should be involved in the implementation of such policies

SPIRITUALITY AND DEPRESSION, QUALITY OF LIFE, AND COGNITIVE DYSFUNCTION IN THE AGED

INSTITUTIONS
1. Hallym University Chuncheon Sacred Heart Hospital, Family Medicine, Chuncheon, Republic of Korea
2. Hallym University Chuncheon Sacred Heart Hospital, Psychiatry, Chuncheon, Republic of Korea

AUTHORS
1. Yoo Sun Moon1, Dr, M.D., Ph.D., yoosmoo@hallym.ac.kr
2. Do Hoon Kim2, Dr, M.D., Ph.D., dohkim@hallym.ac.kr

Aims/Objectives: This study was to examine the following hypothesis: those with higher spirituality 1) have lower depression scores 2) have higher quality of life scores 3) have less cognitive dysfunction scores.

Methods: relatively healthy adults, over 65 years of age, who live in the community in Gangwon Province, Korea (N=344; M=59, F=285) participated the study. A trained interviewer filled out several questionnaires; DUREL (Duke University Religion Index), Geriatric depression scale - shore form, Quality of Life score, MMSE-K (mini-mental status examination - Korean version). The blood sampling was drawn to evaluate cholesterol, fasting blood glucose, and amyloid-â protein 42.

Results: The mean age was 76.91±6.28 and most of them (96.8%) don’t have jobs. Many of them (65.0%) have religions; Christianity 29.7%, Buddhism 16.6%, Catholic 14.2%, Shamanism 2.7%. Mean depression score was 9.84 and most of the subjects have depression; 28.5% with minor depression and 61.9% with moderate depression. Those who attend religious services frequently have lower depression scores and higher quality of life scores. Those who have religious activities regularly (at meeting places and/or alone at home) have less cognitive dysfunction, which are shown in lower MMSE-K scores.

Conclusion: Higher religious attendance was associated with lower levels of depression and cognitive dysfunction.

DELIBERATE SELF-HARM AND SELF-DISCHARGE: A VULNERABLE POPULATION

INSTITUTIONS
1. Beaumont Hospital, Department of Psychiatry, Dublin, Ireland

AUTHORS
1. Diane T Mullins1, Dr, Diane.Mullins@iop.kcl.ac.uk
2. David R Cotter1, Prof, drcotter@rcsi.ie
3. Siobhan M MacHale1, Dr, siobhanmachale@beaumont.ie

Aim To study the characteristics of deliberate self-harm patients who leave accident and emergency departments without a psychiatric assessment.

Background review It is important that deliberate self-harm patients who attend accident and emergency departments receive a psychiatric evaluation that will minimise the risk of their future self-harm or suicide.

Method All patients triaged within Beaumont Hospital accident and emergency department with a presentation indicative of psychiatric disorder were studied over 12 months. The following were collected on each patient: demographic variables (age, gender, marital status), clinical variables (method of self-harm including associated factors, self-harm history, overdose agents used in self-poisoning, whether a psychiatric consultation occurred and outcome). Dates and times of presentations were recorded. Statistical analysis was performed using SPSS15 statistical package.

Results 1,397 liaison psychiatry patients presented to the accident and emergency department over 12 months. 834 (60%) cases were deliberate self-harm, most commonly overdose (78% of the self-harm patients). Alcohol ingestion was associated with 353 (43%) cases of self-harm. History of deliberate self-harm was found in 444 (54%) of the deliberate self-harm patients. 152 (18%) of the patients presenting with deliberate self-harm left before being seen by psychiatry. 65 (5%) of these patients who left were single males aged 40 years or less. These characteristics are associated with increased risk of suicide.

Conclusions Deliberate self-harm patients who present to accident and emergency departments represent an important patient population. A more co-ordinated approach is required to reduce the future risk of self-harm or suicide occurring in this vulnerable group.

USERS AS TRAINERS: WHAT CAN USERS TEACH TO MENTAL HEALTH PROFESSIONALS: A PARTICIPATORY ACTION RESEARCH PROJECT

INSTITUTIONS
1. Mental Health Training Unit, Castellon, Spain

AUTHORS
1. Carla Ramos1, Mrs, MD
2. Maria Ballester1, Mrs, PhD
3. Candela Santiago1, Mrs, PhD
4. Mikel Munarriz-Ferrandis1, Mr, MD, mikelmf@comcas.es

Users are first-hand experts in their illness. This expertise has been always recognized, but keeping patients in a passive role as "clinical examples". The present communication shows the rationale and development of a training workshop addressed to mental health trainees whose teachers are persons with severe mental disorder.

Method: A qualitative method (participatory action research) Project has three steps:
1. Reaching the expertise field of patients. We use focus groups with users and carers.
2. Collaborative work with selected patients to develop a course based on the topics obtained from focus groups. This phase includes training of patients in training and communication skills.
3. Implementation of the course in a real setting, with qualitative evaluation of trainers and trainees.

Results: Topics elected by users (support to personal autonomy, relapse prevention, interest in the whole person) were developed for being used in a 4 hours workshop. Mental health workers in the research team act in a collaborative way.

Results are positive in terms of patients’ empowerment and mental health professionals’ experience.

**EFFECTIVENESS OF EARLY DETECTION AND TREATMENT FOR WORKERS WITH MENTAL PROBLEMS RELATED TO JOB STRESS**

**INSTITUTIONS**
1. University of Occupational and Environmental Health, Dept. Mental Health, IIES, Kitakyushu, Japan

**AUTHORS**
1. Shoji Nagata¹, Dr., MD, s-nagata@med.uoeh-u.ac.jp
2. Hisanori Hiro¹, Dr., MD, hiro@med.uoeh-u.ac.jp
3. Kousuke Mafune¹, Mr., PhD, kmafune@med.uoeh-u.ac.jp

**Purpose**
Mental health at work is very important issue in Japan. The purpose of this study is to investigate effectiveness of early detection and treatment of the cases by internal EAP (employee assistance program) in the company comparing with outpatient clinic cases.

**Method**
Subjects were 162 EAP cases with mental problems visited health care center in a manufacturing company and 113 outpatients visited psychosomatic units in 2 general hospitals. We compared the diagnosis, job stress, effectiveness of treatment and final outcome of both cases.

**Results**
Depressive cases (43.4%) were significantly much more in outpatient cases compared to EAP cases (25.3%). Stressors related to job contents were significantly more in male workers than female workers in both cases. An arrangement of work environment were done in 55.6% of EAP cases and effective in 90.0% of those, done in 20% of outpatient cases and effective in 65.2% of those. Finery, 79.9% of 162 EAP cases were completely cure, 10.3% were continued medical treatments, 1.9% steel in sick leave, 4.9% moved to other companies, 27.4% of 113 outpatients cases cure ,31.0% continued ,19.5% dropped out, 3.5% in sick leave, 17.5% moved, 22.1% changed hospitals.

**Conclusion**
Final health outcome seems better in EAP cases comparing to outpatient cases, because early detection & early treatment and arrangement of work environment is easier in EAP cases.

8. Kazuya Ono¹, Dr, MD, PhD
9. Wataru Yamadera¹, Dr, MD, PhD
10. Kazuhiro Nakayama¹, Dr, MD, PhD

**Introduction:**
Recently in Japan, the myth of the lifetime employment collapsed and the environment that surrounded the employees changed dramatically. As even a big company go bankrupt or come to do business integration, the company gave priority to efficiency and came to differentiate an individual by personal ability. Therefore the employees are exposed to stress and struggles in the environment that turned worse. So the increase of depression and suicide of the employees by the overwork are recognized as a social issue. It is said that the depression of the employees increases because the stress is increasing, but it is too simple to answer the cause. We thought it was significant to investigate actually what caused the employees maladjustment.

**Method:**
We surveyed 44 psychiatric outpatients who were absent from work. They completed NEO-FFI, MPS, Rosenberg's self-esteem scale and the original question items. We also investigated age, sex, the type of job, times of change of job, support of family, employment form, workplace environment, GAF and psychiatric diagnosis.

**Results:**
In MPS, "Doubt about Action" score (28.1±8.3) was high and the scores of others were not. In NEO-FFI, 'Neuroticism' score (31.7±6.6) was significantly higher than the controls (23.4±6.9) and 'Extraversion' score(20.5±6.7) was significantly lower than the controls(23.2±5.8).

**Discussion:**
In Japan, the employees who have high perfectionism tend to be absent from work. High perfectionism employees seem to undertake too much job and be exhausted in complicated human relations in the workplace.

On December 26th 2004, the nation of Sri Lanka experienced a devastating tsunami where at least 34,000 died, 15,000 were injured, and 483,000 were displaced. This catastrophe left thousands of families having to cope with an incredible trauma. As the predominant religion for the largest ethnic group, Theravada Buddhism offers individuals ways of dealing with existential questions and psychological trials. We will identify Buddhist concepts relevant to tragedy. We will review the disaster relief efforts and discuss whether Buddhist notions were incorporated into this process. We will interview psychiatrists, public health officials and Buddhist monks who live in Sri Lanka in a descriptive study. We will use a pre-identified set of questions exploring mechanisms of dealing with tragedy. These results will be reviewed. Finally, this workshop will describe Buddhist techniques of coping, primarily Vipassana meditation. The participants will receive basic instruction on meditation which can be incorporated into their own clinical practices. In conclusion, we will explore the possibilities of making a model for future disasters in the U.S. Educations Objectives: by the end of the seminar, participants will: 1. Gain familiarity with basic Buddhist concepts 2. Be exposed to cultural variations in response to tragedy. 3. Learn simple meditation techniques.

AIMS: The aim of this study is to explain the place of psychoanalytic information in daily life. According to the Social Representations Theory (Moscovici, 1984, 1988, 2001) the combination of common-sense knowledge and the scientific knowledge reproduce a new form of common-sense knowledge. Social representations are formed in and through confrontation and transformation of scientific and common-sense knowledge (Moscovici, 2008). The psychoanalytic information has been recognized in daily life. Thus it is possible to mention the social representation of psychoanalytic information in Turkey. However there hasn't been any studies on the social representations of psychoanalysis in Turkey. Therefore the phenomenon has been examined.

METHOD: In this study nine daily newspapers published between the years of 1980-2005 has been analyzed by content analysis in order to understand the introduction of psychoanalytic information in society. A survey has been used in order to identify the reflection of this introduction on individuals. The 73 itemed survey has been desinged by researchers. It has been applied to 1080 people among ages of 20-60.

RESULTS: The results are being assessed.

WHAT DO PATIENTS WANT TO KNOW? ANALYSIS OF THE QUESTIONS POSTED BY USERS OF AN INTERNET-BASED INFORMATION SERVICE ON PSYCHIATRY AND MENTAL DISORDERS

INSTITUTIONS
1. Associação Brasileira de Psiquiatria, ABP Comunidade, Rio de Janeiro, Brazil

AUTHORS
1. Antonio I. Nascimento¹, Dr., antonio.leandro.nascimento@gmail.com
2. João A Carvalho¹, Dr., joaoagc@uol.com.br
3. Marco A Brasil¹, Dr., brasil@uninet.com.br

Introduction: Over the last decade, several databases on health topics (both focused on professional and patient information) have become available over the internet. In spite of the widespread use of the internet to obtain information on health topics, few studies have addressed the patients need for information and their satisfaction with the information services available.

Objective: to analyse the demands of the users of an internet based psychiatric information service on the disorders which generate most questions and on the demands about each diagnosis.

Methods: Questions sent to the ABP Comunidade service over a one year period have been classified according to the user's data (sex, place of living among others), the mental disorder it was related to and on the demand of the user.

Results: 66.6% of the questions were asked by women and 33.3%, by men. 20% of the questions were sent by patients and 23.3%, by relatives. The mental disorders which generated most questions were: Bipolar Mood Disorder (13.3%), Depression (10%), Addiction (8.3%), Panic Disorder (5%) and Schizophrenia (5%). The most frequent demands were: indication of and institution for treatment (30%), information on incidence, evolution and treatment (18.3%) and indication of literature on the subject (11.6%).

Conclusion: The internet might be an efficient mean to provide information on health topics. More studies are needed to evaluate if the information is adequate for the patients' needs.

ATTITUDES OF HOSPITAL WORKERS IN A NIGERIAN TEACHING HOSPITAL TOWARDS MENTAL ILLNESS

INSTITUTIONS
1. Irrua Specialist Teaching Hospital, Medicine, Irrua, Nigeria
2. Lagos University Teaching Hospital, Psychiatry, Lagos, Nigeria
3. Irrua Specialist Teaching Hospital, Obstetrics and Gynaecology, Irrua, Nigeria

AUTHORS
1. Rosalind R Ohiosimuan¹, Dr, roliohio@yahoo.co.uk
2. O O Famuyiwa², Dr
3. Okunweme I Ohiosimuan³, Dr

Aims: The main aim of the study was the investigation of the attitudes of staff at the University of Benin Teaching Hospital, towards mental illness and to ascertain the effect if any of contact and demographic characteristics on these attitudes.

Methods: A total of 396 hospital staff (104 clinicians and 292 non clinicians) were interviewed with a questionnaire which was made up of two sections, one on demographic characteristics and the other an abridged 'Opinions about Mental Illness' scale. The opinion statements were on five factors (Authoritarianism, Benevolence, Mental hygiene Aetiology, Social Restrictiveness Interpersonal Ideology).

Results: Demographic characteristics in this case; age, gender and education played a significant role in attitude formation. Religion also had an effect on attitudes but to a lesser extent. The clinicians had more positive attitudes than non clinicians, scoring lower on factors of Authoritarianism and Social Restrictiveness and higher on the Interpersonal Ideology factor. Amongst these clinicians, a comparison of psychiatric clinicians and non psychiatric clinicians, revealed more positive attitudes in psychiatric clinicians with statistically significant differences on the scales of Authoritarianism and Interpersonal Ideology.

Conclusion: These observations (clinical staff with more positive attitudes and psychiatric staff the most positive attitudes) might be a result of their education. In most medical schools and nursing programs in Nigeria psychiatry is an integral part of the curriculum. As for psychiatric personnel they have sustained contact with the mentally ill which could further influence their attitudes.

Background: In Japanese psychiatric emergency service, increasing number of suicidal patients and elderly psychiatric patients with comorbidity illnesses demands more effective liaison psychiatric service. But, the number of psychiatric ward in a general hospital is limited. As a result, some patients with physical illness tend to be transferred to a psychiatric emergency service without other specialized care.

Aim: We assess the number of cases referred from general hospital with physical comorbidities to clarify the most common liaison problem.

Methods: We picked up 42 cases who were referred from general hospital in 951 records of psychiatric emergency phone call(2005-2006 year ,Tochigi pref.) a retrospective case note review, looking at psychiatric problems and complications.

Results: 24 cases in outpatient settings consisted of 14 (58%) cases of mood disorder, 17(70%) female patients. Mean age was 35.5 years old. The most common physical problem was injuries or drug overdosing by suicidal attempts (50%). 18 cases in inpatient settings consisted of 7 (41%) cases with substance abuse, 5 (28%) cases with schizophrenia. Mean age was 44.1 years old. As a comorbid illness, suicidal injury, alcohol withdrawal symptoms were common. Mean length of hospitalization was 31.6 days. 2 cases required to be retransferred to the general hospital.

Conclusion: A case with suicidal injury was the most common liaison psychiatric problem in this psychiatric emergency service.

Objectives: Patient satisfaction is an indicator of the quality of care provided by emergency department personnel. To identify factors associated with willingness to return to and recommendation of the emergency department to others a study was conducted using a valid (based on a qualitative study) and reliable questionnaire (Cronbach’s alpha coefficient = 0.91).

Methods: The study was carried out in emergency department in five major teaching hospitals in Tehran, Iran (n=153). Patients who had been in emergency department at least for 10 hours, did not have significant cognitive problems, and were well enough to answer the questions were included in the study.

Results: 33% of the patients reported that they would not refer to the same emergency department again and 20% of the respondents expressed that they would not recommend the emergency department. All five subscales and overall satisfaction were found to have a significant correlation with willingness to return to and recommendation of the emergency department to others (P<0.001). Physicians’ care (including feeling responsibility, being skilled, giving information, being kind, respecting to patients, being compassionate, having interest in work, and not being negligent) had the strongest relationship with future emergency department choice and the recommendation of the emergency department to others (0.661 and 0.656 respectively) considering subscales.

Conclusion: The study findings indicate the importance of perception of satisfaction regarding willingness to return to and recommendation of the emergency department to others. The study emphasizes that physicians’ care had the strongest correlation with the variables compared with other subscales.

Objectives: Patient satisfaction is essential for ongoing monitoring of quality of health care services, reflects the meeting of patients' needs and expectations, and is associated with recommendation of health care systems to others. (1, 2)

Methods: To identify factors associated with recommendation of the psychiatric wards to others a study was conducted using a valid (based on a qualitative study) and reliable questionnaire (Cronbach’s alpha coefficient = 0.96) at 17 acute psychiatric wards in 8 different hospitals (n=140: 30% of the patients reported that they would not recommend the psychiatric ward. All five subcales and overall satisfaction were found to have a significant correlation with recommendation of the hospital to others (P<0.001). Nursing care (including compassion, explanation, respect to patients, kindness, attention to patients' demands or protests, skillfulness, interest in work, and patience) had the strongest relationship with the recommendation of the psychiatric ward to others (p = 0.758) considering subscales.

Conclusion: The study findings indicate the importance of perception of satisfaction regarding recommendation of the psychiatric ward to others. The study emphasizes that nursing care had the strongest correlation with the variable compared with other subscales.

Objectives: Quality of care is not merely limited to clinical care, but it also includes patients' experiences regarding received care. A study was carried out to reveal quality of care beyond the words of psychiatric inpatients about their experiences at psychiatric wards.

Methods: A qualitative study was carried out at eight acute psychiatric wards in three teaching hospitals in Tehran, Iran. 28 patients whose symptoms and signs had subsided and who had stayed in hospital at least 7 days or previously experienced being hospitalized at a psychiatric ward were interviewed using purposive sampling and semi-structured open-ended individual in-depth interviews. Interviews went on until it was concluded that information was saturated. The data were then coded and classified on the basis of the area and subject.

Results: The findings of the study included different pivots need for improving some of which are as follow: Lack of policies and procedures or their implementation, the mission of the psychiatric ward/hospital, offered facilities and services by psychiatric department to the patients, implementation of the construction standards of psychiatric hospital, taking care of the patients, psychiatry staff qualifications, their time, and availability; educating and training of the medical and non-medical personnel, patients’ rights, psychiatric ward equipment, investigating complaints, safety and security precautions, procedures to assure the quality of psychiatric services, access to open and sports space, visiting regulations, discharge plan, and ...

Conclusion: The study findings indicate the necessity for a program to ensure quality of services delivered to the psychiatric inpatients.

At the beginning of the first story of Mathnavi, the Sufi poet Jalal al-Din Rumi says that Mathnavi is the analysis, psychoanalysis of our condition, of ourselves. Starting from this fact, through several illustrations this paper indicates the essential connections between Rumi’s teaching and contemporary psychotherapeutic doctrines. This connection is expected and logic since each of these disciplines is dealing with the psychic life, intended to find the ways and methods to achieve health, serenity, complete fulfillment and self-actualization. The main elements of spiritual experience such as: sense of wholeness, holiness, unity, objectivity and reality; a joy, happiness, peace, bliss, positive change of attitudes and behavior, represent desirable ideals resulting from a good psychotherapeutic process. In this context, the Mevlevi Sufi teaching and practice can be a very interesting research field of modern psychotherapeutic theory and practice for it unites all those elements necessary for advancement along spiritual continuum and achievement of the highest levels of mental health and growth.

Key words: Jalal al-Din Rumi, Sufism, Psychotherapy

Objective: to examine the appraisal of caregiving experience by relatives of patients suffering from sever mental disorders in Hong Kong

Methods: Relatives were assessed with the Chinese version of The Experience of Caregiving Inventory. Clinical correlates of the appraisal of caregiving were evaluated with the Brief Psychiatric rating Scale. Scale for assessment of Negative symptoms, and the Mastery Scale.

Results: 81 patients and 129 caregivers were recruited. there was a positive correlation between positive and negative appraisal as measured by the Experience of Caregiving Inventory (r=0.32, p=0.003) . A regression analysis showed that negative appraisal was influenced by the Global assessment of function of patients 1 year prior to index admission, and the educational levels of the caregivers.

Conclusions: The caregiving experiences were affected by different factors. Interventions should focus on the specific needs of the families

The purpose - revealing and rehabilitation posttraumatic stress disorders (PTSD) on people after an air crash.

Objective: 236 persons becoming eyewitnesses of an air crash in item the Suha Balka on 22 August 2006.

Methods: Mississippi scale - scale PTSD.

Results: 118 pers. (50.0 %) are marked norm (PTSD were not fixed); at 71 pers. (30.1 %) are revealed separate attributes PTSD; at 47 pers. (19.9 %) are diagnosed presence PTSD. Among 118 pers., who separate attributes and presence PTSD are marked, 45 pers. (38.1 %) were witness an event, 30 pers. (25.5 %) accepted active participation in liquidation of consequences of failure, 47 pers. (36.4 %) do not witness an air crash. 71 pers. (30.1 %) surveyed at which it is marked expressed psychoemotional pressure, unsatisfactory psychological and emotional condition, require the expanded psychological inspection and probable psychocorrectional actions. 47 pers. (19.9 %) who presence PTSD is diagnosed, are necessary carrying out of medical actions! The offered complex of rehabilitation actions included: 1) preparation for active cooperation by removal of emotional pressure, aggression, mistrust and training of methods of mental self-control; 2) the sanction of psychological problems and internal conflicts rehabilitated; 3) personal growth, development of communicative activity and competence.

Conclusions: A ultimate goal of rehabilitation PTSD at the persons becoming eyewitnesses technogenic accidents and failures is restoration of the personal and social status. It is important to provide continuity of stages of regenerative actions. Acceptance of measure considerably is duly raise efficiency of treatment and rehabilitation of boundary mental frustration.

The purpose - description of clinico-psychopathological model of mental frustration at liquidators of consequences of failure on the Chernobyl power station.

Objective: 110 man in the age of 26-56 years. All examinees have diagnose encephalopathy also it is established diagnose «organic disease of the brain».

Methods: clinical (making «Clinic-epidemiological card of studying of psychical disorders at liquidators of consequences of failure on the Chernobyl power station»); experimental - psychological; EEG.

Results: psychoorganic syndrome - 99 pers., its asthenic form is found in 69 patients, explosive form - 30 pers. At patients have a reduction of memory. At 30 pers. (23.3%) was marked moderately high. At surveyed prevailed (96 pers. - 87.6%) REG hypertonic type, a dystonia of brain vessels, difficulty venous outflow (84 pers. - 76.6%). The organized type EEG with prevalence α-rhythm and by preservation of zone distinctions it is marked at 3 pers. At 30 pers. are established diffuse changes. Hyposynchronous type EEG is observed at 5 pers., disorganized type - at 3 pers. Epileptic forms of activity are observed at 14 pers. results testify to microstructural changes of a brain.

Conclusions: Mental disorders of liquidators of consequences of failure on the Chernobyl power station concern to egzogenic-organic and differ advancing.

Leading place among adaptable processes is occupied with adaptation of the person to labour activity. The effective labour activity of the new worker promoting optimum performance of the enterprise will testify to success of adaptation.

Objective: Research of features of adaptation of the person to production has been carried out on 115 persons which activity is connected to work in conditions of chemical manufacture. Middle age of examinees has made 46,0±2,0 years.

Methods: method of color elections by Lusher, a scale of a self-estimation of jet and personal uneasiness by Spilberger & Hanin, storing of 10 words, tables by Shulte, proof test have been used.

Results: the low level of adaptation is revealed at 31 pers. (26,9±1,4%). Thus the majority of them work at the enterprise no more than 6 months. Besides at 13 pers. (11,3±3,0%) was fixed consumption mental activity, reduction in efficiency mnemonic functions, and also functions of active attention and sensomotoric activity was observed. The high level of jet and personal uneasiness is revealed at 6 pers. - 5,2±2,2%. High jet and personal uneasiness is examined as one of the main reasons of low stability to stress and predetermines the further development of adaptable processes in all functional systems.

Conclusions: The revealed features of adaptation of technicians in conditions of chemical manufacture can influence labour productivity, lead to erroneous actions on workplace and traumatization. Duly revealing of the given features allow to prevent and essentially to lower level of professional disorganization of activity.

PSYCHOPHISIOLOGICAL AND PSYCHOLOGICAL READINESS TO LABOUR ACTIVITY

INSTITUTIONS
1. Ukrainian Engineering Pedagogics Academy, Faculty of Pedagogic & Engineering Psychology, Kharkov, Ukraine

AUTHORS
1. Lyudmila V. Panchenko¹, Mrs., rdckonst@mail.ru

The research has been directed on studying of individual - psychological features, revealing of readiness for performance of labour activity, and also dependence stress stability from psychophisiological features at the persons who were taking place selection on the industrial enterprise with harmful working conditions.

Objective: it has been surveyed 115 person, candidates on employment in Konstantinovski the state chemical plant where professional work of workers is connected to harmful working conditions. Middle age of examinees has made 46,0±2,0 years.

Methods: method of color elections by Lusher, a scale of a self-estimation of jet and personal uneasiness by Spilberger & Hanin, storing of 10 words, tables by Shulte, proof test, technique visual - motor reactions.

Results: at 13 pers. (11,3±3,0%) it is fixed consumption mental activity, decrease in efficiency mnemonic functions, and also functions of active attention and sensomothory activity was observed. At examinees with frustration of memory the level of emotional stress is characterized by the expressed emotional intensity, having tendency to increase (7 pers. - 6,1±2,2%). The high level of jet and personal uneasiness is revealed at 6 pers. - 5,2±2,2%.

Conclusions: The persons with infringements psychophisiological functions, infringements of short-term storing and reduction in long-term memory, infringements of concentration and stability of attention, consumptions nervous system do not recommend a kind of activity where there is a raised danger of a professional traumatism, i.e. work in harmful conditions. The revealed features psychophisiological parameters and a low level stress stability influence labour productivity, can lead to erroneous actions on the workplace and traumatism.

ASSESSMENT OF LEVEL OF POLISH PSYCHIATRISTS WORK SATISFACTION

INSTITUTIONS
1. Medical University of Gdansk, Psychiatry, Gdask, Poland

AUTHORS
1. Piotr Pankiewicz1, Dr, MD, pankiew@amg.gda.pl
2. Bartosz Kotkowicz1, kotbar@hotmail.co.uk
3. Magdalena Lemska1, MRS

Aim: The aim of this work was to assess whether Polish psychiatrists are satisfied with their chosen profession, and whether psychiatry is still an attractive specialization for students and young doctors.

Methods: The method used in this study was an original questionnaire prepared in the Department of Psychiatry, Medical University of Gdansk. It consisted of 29 questions and personal inquiry. The test was voluntary and performance time was not limited. Material: We analyzed questionnaires collected from 125 psychiatrists from all districts of Poland (92 women, 33 men). Among them, there were 7% with the first degree of specialization, 58% with the second degree, 8% during the second degree, 21% during the new mode of education, and 6% after the new mode of education.

Results: 82% of questioned psychiatrists claim that they are satisfied with their profession. This tendency is verified and confirmed by other answers: 71% of questioned doctors admit that they would not change their profession. If there is an opportunity to work abroad, 15% of them will leave, 49% will stay in Poland. Rest of them will have to consider this decision. Doctors declare that their work gives them certainty of employment and possibility to enlarge their experience. They find their specialization noble in society. Questioned psychiatrists were asked to rate their salaries: 9% defined their income as high, 44% evaluated it as average, 47% as low or very low. Major part of questioned doctors claim that they can not spend as much time with their families as they would like to.

Conclusion: According to analysis, there is a high level of integration with the profession. Questioned doctors are satisfied with the choice of specialization. Nevertheless, they point vulnerable places in Polish psychiatry.

2. Nota Voura1, PSYCHOLOGIST, aponota@hol.gr
3. Theodoros Avgerinos1, PSYCHIATRIST
4. Zinovia Navrozidou1, SOCIAL WORKER

Objective: The Psychiatric Hospital of Petra Olympus in Katerini, Greece is the first Greek psychiatric hospital that closed its chronic wards in January 2004. It has transformed into a Network of Community-based Psychiatric Services. The only ward that is still running is the acute ward. It involves a small clinic of 22 beds which covers its catchment's area of 1000000 people. It is open 24 hours a day, all year round. The purpose of this poster is to demonstrate the staff burnout of this clinic. Job burnout is a prolonged response to chronic emotional and interpersonal stressors on job. It affects work performance, health and personal life. Health care professions by definition tend to be on higher stress.

Method: The study is based on structured interviews with the members of the staff, as well as on Maslach Burnout Inventory (MBI), and Beck Depression Inventory (BDI). The same procedure was followed for all the 33 members of the staff (doctors, psychologist, social worker, health visitor, nurses, and assistant staff).

Results: Through the analysis of the data was possible to conclude that more ‘burned’ are the members of the staff who work in the acute ward for more than 4 years. Also, staff having an academic background seems to be more prone to job burnout.

Conclusion: Since job burnout is a reaction to work stress, affecting the work performance, methods of handling stress can be identified and encouraged. Work can be done towards helping them gain control over their work life.

2. Ivan Tuma, Prof., Doc. MUDr.
3. Michael Povey, Mr., MS
4. Annette Lam, Ms., MS
5. Zhongyun Zhao, Dr., PhD

Objective: To assess remission in schizophrenia patients treated with risperidone long-acting injection (RLAI) enrolled in the electronic-Schizophrenia Treatment Adherence Registry (e-STAR) in Czech Republic and Slovakia.

Methods: e-STAR is an international, long-term, prospective, observational study of patients with schizophrenia who commence RLAI. Data are collected retrospectively (1 year) and prospectively (2 years). Remission is evaluated using clinician assessed symptoms of: delusions, conceptual disorganization, hallucinatory behavior, mannerisms and posturing, unusual thought content, blunted affect, passive/apathetic social withdrawal, and lack of spontaneity and flow of conversation. Patients in whom all of these symptoms are absent, minimal or mild were considered to be in cross-sectional remission and if this persisted for at least 6-months, they were considered to be in symptomatic remission. This interim analysis is based on data from patients who have completed their 18-month follow-up visit.

Results: Total 1324 patients have been enrolled in e-STAR from the Czech Republic and Slovakia; 296 patients with at least 18-months of data available (97.3% still on RLAI) were included in this analysis. Mean age was 37.6±12.1 years with 53.7% male, and mean time since diagnosis 9.6±9.0 years. During 18-month treatment with RLAI, proportion of patients met criteria for cross-sectional remission increased from 2.4% to 38.6% (p<0.001); percent patients who achieved symptomatic remission was 1.1%, 22.0%, and 28.6% at 6, 12, and 18-months respectively (p<0.001).

Conclusions: This interim analysis suggests that after 18-month treatment with risperidone long-acting injection in patients with schizophrenia, over one-third fulfilled cross-sectional remission criteria and some even achieved symptomatic remission.

PRESS OFFICER OF A PSYCHIATRY DEPARTMENT: WORK AIMED AT PSYCHIATRY DESTIGMATIZATION

INSTITUTIONS
1. Medical University, Psychiatry, Rostov-on-Don, Russian Federation

AUTHORS
1. Alexei Perekhov, Dr., perekhov@pochta.ru

Objective: To show the role of the press officer within a leading and most prestigious mental facility of the region - University Department of Psychiatry - in psychiatry destigmatization.

Methods: In 1994, first in Russia, a Psychiatry Department introduced the post of a press officer, thus starting to systematic collaborate with mass media.

Chief duties: Destigmatization, discrimination negotiation, prevention of invasion on privacy, implementation of the “mental health” principle, struggle with shamanism, parapsychology, discussing anti-psychiatry, informing people on the opportunities of modern psychiatry, new ways of diagnostics, therapy, after treatment, worthy representation of psychiatry as both theory and practice, raising in the social and professional status of experts and mental service people's opinion, legal consulting of patients, their relatives, etc.

Results: during the last 13 years published have been over 80 original articles on the acute problems of psychiatry, psychotherapy, addictology. More than 250 materials have been presented as interviews or commentaries to the problems of psychiatry. The Department press officer and staff members have given more than 60 talks on the TV and radio. There is a web-side page for non-professionals. Initially excluded is: any collaboration with yellow and scandalous press, commentaries and claims concerning assumed psychopathology of any person (either living or dead), famous and great personalities included. Pathography is only printed in special or popular scientific editions. The public-opinion polls and practices show greater trust to psychiatrists and psychiatry.

Conclusions: The press officer of a leading mental facility may essentially influence psychiatry destigmatization within the region.

CLINICAL AND ETHICAL ISSUES IN THE TREATMENT OF RUNAWAY YOUTH

INSTITUTIONS
1. University of Quebec (Teluq), Psychology, Montreal, Canada

AUTHORS
1. Mario Poirier¹, Professor, PhD, mpoirier@teluq.uquebec.ca

Objective: To study the use of clinical services by runaway and homeless adolescents.

Methods: Exploratory qualitative research project (funded by FQRSC) with 20 adolescents (16 to 19 years old) and 20 social workers in a youth protection program in Quebec (Canada).

Results: Most of our subjects were victim of family violence and childhood abuse; most have developed mental health and drug addiction problems. The identity and emotional difficulties related to their life history and their resilience in a context of exclusion can be reasonably predictive of the capacity of these youth to seek, accept and maintain a therapeutic relationship. We will present our results and discuss the ethical and clinical issues in dealing with young people that present severe emotional and behavioral difficulties and that mistrust most forms of clinical help due to attachment traumas (former losses and abuses in their childhood).

Conclusions: Services must improve and adapt to the cycles these adolescents go through in their paradoxical needs for support and autonomy.

National AIDS control organization has reported that AIDS is prevalent in all parts of the country. HIV and AIDS afflicted individuals and their families are forced to cope with multitude of stressors. The present study was attempted to see the impact of counseling on the quality of life of HIV/AIDS patients and their carers. It was hypothesized that the counseling would have positive impact. For seeing the impact of counseling a pre-post design was used. The post counseling assessment was done after three months following counseling. The study was conducted on 300 subjects consisting of HIV positive, AIDS cases and their care givers selected from those who visited NACO ICTC centre. The subjects were interviewed on Quality of Life Questionnaire (Flanagan, 1982). The findings suggest that the counseling has a positive effect on all the domains of quality of life of the patients and their carers. The findings are discussed in context of long time home based care of HIV/AIDS patients.

THE LATE EFFECTS OF TRAUMA

INSTITUTIONS
1. Institute of Psychiatry and Neurology, Mental Health Center, Warsaw, Poland

AUTHORS
1. Katarzyna Prot, Dr., MD, PhD, kasiaprot@gmail.com

The objective of the study was to investigate late effect of the trauma. The goal of the study was to assess the level of PTSD and describe other psychological symptoms related to Holocaust survivors’ trauma. The paper is based on the long experience of the group and individual therapy of Holocaust survivors and interviews with survivors in Poland and Romania. For the purpose of the study structured questionnaire describing the circumstances of surviving and the situation before and after the war was used. For evaluation the intensity of PTSD symptoms the Watson’s questionnaire was used. The constant observation during the psychotherapy work with Holocaust survivors is increase of the symptoms in the old age. Many authors put the question that the PTSD late onset or the fluctuation of the symptoms. The survivors were exposed to the different types of trauma. The participants of control group were not exposed to direct trauma nevertheless they suffered because of the racial laws. Nearly all the participants from the study groups have till now the PTSD symptoms what is not the case for control group. There are also the differences between traumatized groups. In my study and observation during the psychotherapy in Holocaust survivors crucial are separation problems, identity problems, vulnerability and survivor’s guilt. The study shows that the PTSD symptoms are still present. However the study also support the theory that PTSD criteria are not sufficient to describe the whole effect of trauma.

During August 2007, wildfires devastated large areas in the Peloponnese. It was a tragedy with no precedent. Specifically in the region of Ilia, where Ancient Olympia is situated, 43 people were killed among whom 3 were firefighters, furthermore thousands lost their property. The firefighters were on duty for several days without sufficient rest, but were able to save the temples and stadium of Ancient Olympia, birthplace of the Olympic Games. We have organized a joint task force of mental health clinicians to provide psychological support and investigate the psychosocial consequences of this catastrophic event. Several questionnaires and inventories were used. One hundred and two male firefighters, living within the fire-devastated area who attempted to control the disaster, were interviewed. One month after the wildfires, post traumatic stress disorder (PTSD) — according to ICD-10 criteria — was detected in 18.6% of the firefighters. It should be emphasized that although the seasonally employed firefighters (n=44) had similar losses to the regular staff, they presented with significantly higher percentages of PTSD (27.3% vs 12.1%). They were generally younger, had higher anxiety on the Spielberger State Anxiety Inventory, and less experience confronting other disasters. Consequently, early detection of specific post-disaster mental health outcomes might be of great importance for the prevention of post-disaster psychiatric symptoms.

PROVISION OF PSYCHIATRIC SERVICES: A COMPARISON BETWEEN NORTHERN ITALY AND NORTHERN NORWAY

INSTITUTIONS
1. University of Verona, Department of Medicine and Public Health, Section of Psychiatry and Clinical Psychology, Verona, Italy
2. University Hospital of Northern Norway, Department of Clinical Psychiatry, Tromsø, Norway

AUTHORS
1. Daniela Pucci¹, Dr., MD, daniela.pucci@gmail.com
2. Alberto Rossi¹, Dr., PhD, arossi@medicina.univr.it
3. Francesco Amaddeo¹, Dr., MD, PhD, francesco.amaddeo@univr.it
4. Grigory Rezvy², Dr., MD, PhD, grigory.rezvy@nlsh.no

6. Michele Tansella¹, Dr., MD, michele.tansella@univr.it
7. Vidje Hansen², Dr., MD, PhD, vidje@alice.it

Objectives: To compare two systems of Community Mental Health Care: Verona in Italy and Northern Norway.

Methods: The European Service Mapping Schedule and the International Classification of Mental Health Care were used to describe quantitative and qualitative aspects of service provision for psychiatric patients, altogether 96 units. Data were collected by face-to-face interviews with the formal leaders of the units, and differences between the two systems were analysed statistically.

Results: Community-based mental health services were well developed in both regions. In Norway, general practitioners are responsible for primary mental health care, functioning as gatekeepers to specialised services, in Verona patients can seek care from specialist services directly. The number of psychiatrists per 100,000 inhabitants was rather similar (Verona: 15.7, Norway: 13.6; p=0.4). The number of clinical psychologists was 2.4 and 23.1 (p<0.01), respectively; and the number of beds was 42.5 vs 91.9 (p<0.01). Day treatment services for non-acute patients were more developed in Norway than in Verona. Coordination of care and integration of services were well developed in both regions, but in Verona continuity of care was organised using a single staff module. Psychosocial interventions were central in both services, but in Northern Norway more emphasis is put on training activities of daily life.

Conclusions: Both service systems were well developed and in accordance with approved principles in community care, but with surprisingly big differences in number of beds and number of professionals. Description and comparisons of mental health services across Europe is possible but requires further refinement.

4. Cristina Queirós²

Aims: Persons with schizophrenia tend to fail using effective coping skills in order to adaptively face daily life stressors. There is evidence linking the use of active problem-solving coping skills to better functional outcomes. However, few studies attempted to analyse the impact of proactive coping skills in functioning and quality of life. The aim of this study was to examine the relative associations between proactive coping skills, emotional distress, self-esteem, functioning and quality of life (QOL) among persons diagnosed with schizophrenia.

Methods: Sample consisted of 23 Portuguese persons diagnosed with Schizophrenia. Measures of proactive coping (Proactive Coping Inventory), emotional distress (Anxiety, Depression and Stress Scale) and self-esteem (Rosenberg Self-Esteem Scale) were correlated with measures of psychosocial functioning (Life Skills Profile) and QOL (World Health Organization Quality of Life Bref). We performed Spearman correlational analysis in order to determine the relationships between variables.

Results: Proactive coping, reflective coping, strategic planning and preventive coping correlated positively with different dimensions of functioning and QOL. Avoidance coping wasn’t correlated with any functional outcome. We also didn’t found significant correlations between distress symptoms and functioning and QOL, excepting depressive symptoms, which were correlated with communication skills and social relationships. Stress symptoms significantly correlated with physical domain of QOL. Self-esteem was positively associated with several quality of life domains.

Conclusions: Schizophrenic patients can positively influence their functional outcomes, QOL and well-being, if using proactive coping strategies and goal striving. These skills should be emphasized in psychosocial rehabilitation programs.

The authors are working in a clinic which had a great experience during some decencies with the application of new conception of resocialisation. The conclusion is that usual treatment with the medicines is insufficient. It must be, in the same time be completed by new habits of work, in order to learn the schizophrenic how to gain money and how to spend it. That suppose a program of working and teaching the skills in group and individually. This approach is able to fight realistically with stigma. It is a very great task which must be assumed by the new generation of psychiatrist, educated in the spirit of value of work and character. Of cause neuroscience will bring probably new insights and medicine, but cannot explain the indispensable need to be included in social life and economic mechanism. That is what the East proposes, but is not able to realize because the orientation as whole society is toward profit not to really help the durable weak and costly patient. That why resocialisation should be teach to new generations and every psychiatrist to know, to become practical and real helping at log term and socially the patient. The same ideology, in the best meaning, is to be preached to the parents. This policy should be supported by the set, medical authority and law. So we can hope at some results in psychiatry. Otherwise, all are just words.

2. S Yenel Ozbay1, DR, MD, syozbay@hotmail.com
3. S Sukuroglu1, DR, MD
4. O Yildiz1, DR, MD
5. M Isingor1
6. M Sercan1

Stigma is a reaction that is given to the one who is different. It always has a negative meaning and it is frequently met by the patients who are in the area of mental health and illness. In this study we analyzed the stigmatizing attitude of health workers towards mentally ill patients, in psychiatry, neurology, neurochirurgy and pulmonology clinics and we compared the attitudes of all health workers who works in these clinics.

Method: The total number of health workers who has attended in this study is 420; (psychiatry 293, neurology 54, pulmonology 36, neurochirurgy 37). Sociodemografic questionnaire and Custodial Mental Illness Ideology (CMI) was given to the attendants. Non parametric variance analysis Kru skal Wallis test, Dunn multiple comparison test, t-test, x2 test are used.

Results: High educational level is associated with positive attitude and due to this situation, attitude of doctors is more positive than the other groups. The comparison of the results of all clinics has shown that most positive attitude found in psychiatry clinics than neurology, pulmonology, neurochirurgy clinics respectively. The custodial attitude was found to be most common in neurochirurgy clinics. The doctors of the neurology clinics was the only group that has a period of working for 6 months in psychiatry clinics.

Conclusion: In this study we found that the factors that directly effect the positive attitude are high educational level and encountering with mentally ill patients.

MEANINGS OF INSTITUTIONAL ROUTINE AND FEARS OF CONTAMINATION AS ATTRIBUTED BY PHYSICIANS AND NURSES TAKING CARE OF HIV/AIDS PATIENTS IN A UNIVERSITY DAY-HOSPITAL IN ITALY: A QUALITATIVE STUDY

INSTITUTIONS
1. State University of Campinas (UNICAMP), Department of Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas, Brazil

AUTHORS
1. Amilton dos Santos Jr.1, Dr., amilton1983@yahoo.com.br
2. Egberto Ribeiro Turato1, Dr., PhD, erturato@uol.com.br

Aims: (a) after historical impact, healthcare and/or research institutions would have gone to build an approach to HIV/AIDS in a routinist way and an increasing banality; (b) with triviality of this disease, fantasies of contamination would have been progressively transferred to the subconscious.

Methods: qualitative using in-depth Semidirected Interview. Sample was composed by five professionals (physicians and nurses) from the General hospital of Padua, Italia, in sequence of an investigation with HIV/AIDS patients. The saturation occurred with fewer subjects because this group was homogeneous. Free floating rereadings of interviews allowed organizing concepts for these two present topics.

Results: research institutions constructed a “banal” approach about AIDS, becoming a “bureaucratic” chapter of textbooks, whereas healthcare institutions have become commonplace to therapeutic measures. Fantasies of contagion from that time have been gradually “inhabited” the subconscious. Concerns have turned nowadays into speeches on real fears that occurred in the past. Emotional reactions remain obviously influential for the professionals’ feelings and behaviour, but most feebile into the dynamics of personal conscience.

Conclusions: Health professionals must be critical, salvaging HIV/ AIDS studies as a genuine medical-humanistic area. They have to be careful in dealing with their own fears regarding to live side by side with HIV/ Aids patients and becoming a way of organizing mental life’s normal conflicts.

SECONDARY GAINS AND METAPHYSICAL CONCERNS ATTRIBUTED BY HIV/AIDS PATIENTS OF A UNIVERSITY DAY-HOSPITAL IN ITALY: A QUALITATIVE STUDY

INSTITUTIONS
1. State University of Campinas (UNICAMP), Faculty of Medical Sciences - Laboratory of Clinical-Qualitative Research, Department of Medical Psychology and Psychiatry, Campinas, Brazil

AUTHORS
1. Amilton dos Santos Jr., Dr., amilton@yahoo.com.br
2. Egberto Ribeiro Turato, Dr., PhD, erturato@uol.com.br

Aims: to discuss if faced with the HIV/AIDS, there would be specific Secondary Gains (SG). This would occur due to a reorganization of affective relationships in their families provoked by changes into their dynamic; and if beliefs/attitudes regarding Metaphysical Concerns (MC) (worldview, religiosity) would bring compensatory meanings related to anguish/fear, considering that HIV/AIDS threatens psychophysical integrity.

Methods: qualitative including psychiatrist’s clinical hearing attitude (1).

Semidirected interview contained nine items (2). Sample was composed by 12 patients from the University Hospital of Padua, Italy. Saturation occurred when information became repetitive. Inclusion criteria: more than 21 years-old and intellectual/emotional conditions to participate.

Results: authors observed psychosocial SG toward impacts of this disease into the dynamics of patients’ familiar environment. Onset of disease may become facilitator of latent positive emotional manifestations. Beliefs/attitudes related to values of MC had meanings of “salvation”, given that this disease still is an irreversible medical problem, considering psychophysical integrity (3).

Conclusions: professionals must be careful, encouraging them to talk about affective relationships. Professionals must be alert that MC are much relevant to these patients and to animate them to search various activities.

Aims Investigation of a frequent dilemma troubling Greek mental patients: whether they should address a Psychiatrist or a Neurologist when there is a need for expert advice.

Methods Patients examined in the Neurological emergency department of “KAT” and “Tzanio” general hospitals during a six-month period (from 11/12/06 to 13/06/07).

RESULTS During that period 4093 patients were examined in the Neurological emergency department of the two hospitals. 720(17,6%) of these patients manifested psychiatric symptomatology. The majority of this population (74,58%) claimed having neurological or other physical symptoms which were not confirmed by any of the clinical or laboratory examinations conducted and met the DSM-IV criteria for a somatoform disorder. But there was also a significant percentage of patients (22,9%) that manifested obvious psychiatric symptoms concerning psychosis, mood, anxiety, sleep and eating disorders. It is notable that a 21,11% of these patients had at some point visited a psychiatrist and a 20,97% had been receiving psychiatric treatment.

Conclusions Although Psychiatry and Neurology have been separated in Greece two decades ago, it appears that Greek patients still find it difficult to make the distinction. And if in Somatoform disorders, it is indeed hard to identify the underlying psychological factor, this surely is not the case in schizophrenia or depression. Inadequate informing, cultural biases, fear of social stigmatization or even a constant need for confirmation from a physician, possibly keep deterring Greek mental patients from addressing a psychiatrist.

Aims: Assessment of the possible psychological burdening experienced by caregivers of mental patients.

Methods: A questionnaire including, among other parameters, a self-rating scale for depression was given to 19 accompanying persons of psychiatric outpatients in their scheduled appointment during a one month pilot phase of a study investigating the experience of caregivers of the mentally ill.

Results: Sixteen out of nineteen where first-degree relatives (mothers in 13 cases) and were cohabiting with the patient they escorted. The mean duration of illness of their relative was 17.88 years and 7 (< 37%) of them had no assistance in taking care of the patient. The highest score in the depression scale -meaning very high levels of depression- was 30. The mean score of the participants was 16.5 with 7 out of nineteen (< 37%) scoring more than 20. Caregivers who had someone to assist them in care were less probable to score high (> 20) in the depression scale. The ones who scored high in the depression scale were relatives of patients with a longer duration of illness.

Conclusion: The findings of the study, although coming from a very small pilot phase sample, suggest that taking care of someone with a mental illness, may be a stressful experience, provoking depressive symptoms. It seems that sharing the responsibility is comforting, especially in cases of life-long illness.

THE REASONS FOR PSYCHIATRIC HOSPITALIZATION

INSTITUTIONS
1. ANTALYA STATE HOSPITAL, Turkey
2. AKDENIZ UNIVERSITY, SCHOOL OF HEALTH, Turkey

AUTHORS
1. Nimet Saygin, Ms, BSN, nimetsaygin@yahoo.com
2. Kadriye Buldukoglu, Dr., PhD, bkadriye@akdeniz.edu.tr

Background / Objective: Psychiatric hospitalization have bad effects as much as good effects on the patient, the family and the society. For that reason, defining the factors that cause psychiatric hospitalization has great importance. The aims of this study was to define the reasons of psychiatric hospitalization with the patients’ perspectives and the effective factors on the reasons of psychiatric hospitalizations.

Methods: A sample of 450 patients who had psychiatric hospitalization were participated in this study. The data obtained from this study were assessed by using SPSS 13 programme.

Results: At the result of this study, according to the patients the reasons of psychiatric hospitalization were determined as follows: "to have anxiety, tension and psychological discomfort (45.6)"; "to deserve to get rid of his/her illness and to get treatment (35.6)"; "unable to follow the medical home-based treatment (5.5)"; "to be away from family, home and society (18)"; "not to be self-harmed and violent to others (12.7)"; "unable to sleep and eat (6.9)" and "mentally unbalanced behaviours (6.1)". In addition to this, some patients (1.4%) were not know why they have psychiatric hospitalization. Patients’ sexuality, age, educational degree, number of children, profession and the environmental conditions were determined as the effective factors on the reasons of psychiatric hospitalization.

Conclusions: According to the results of this study, it is thought that unneeded hospitalization can prevented by using adequate nursing interventions to sustain coping with mechanisms of the patient and his/her family.

THE PSYCHIATRIC EMERGENCY SERVICE IN THE PUBLIC MENTAL HEALTH SYSTEM

INSTITUTIONS
1. SUNY at Stony Brook, Psychiatry and Behavioral Science, Stony Brook New York, United States

AUTHORS
1. Mark J Sedler¹, Dr., MD, MPH, mark.sedler@sunysb.edu

Public mental health services evolve around 3 factors: 1) population based need as it emerges in a particular social and cultural context, 2) existing mental health services and infrastructure, 3) governmental vision and commitment to address selected social and mental health issues as they arise. Historically the chronic mentally ill have been shuttled between institutional quarantine and homelessness with uncoordinated private and public initiatives providing a variety of intermediate options that often depend on social/economic class and family support. The experience in New York of deinstitutionalization has helped to define a range of alternative services that strive to provide a cost-effective and integrated system of public mental health. These include limited acute care and long term inpatient care capacity together with partial and day hospital programs, supervised and unsupervised housing options, emergency shelters, outpatient clinics, intensive case management, ACT teams, AOT, specialized MICA treatment, emerging consumer driven rehabilitation services, and the advent of the CPEP. This latter development, the Comprehensive Psychiatric Emergency Program, can be viewed as the cornerstone of the system in that it provides critical services at the most vulnerable point in the cycle of exacerbation and remission characteristic of most serious mental illness. CPEP provides a range of evaluation and stabilization measures, reduces hospitalization rates, establishes an efficient locus for triage to alternate levels of care, and serves as an epidemiologic instrument for the assessment of both prevalence and service needs.

10. Alexandros Gerontas¹
11. Konstantinos Paraschakis¹
12. Christos Garnetas¹
13. Konstantinos Kontis¹

Aims: Mental illness is often a chronic and disabling condition which often renders independent living not possible for patients, especially in the absence of a well organized supporting health and social system or family. We investigated the role of caregivers.

Method: During a pilot study concerning the burden of the caregivers of the mentally ill in July 2007, in an outpatient clinic, nineteen questionnaires were administered to persons accompanying the patients for their follow up visits.

Results: From the nineteen persons sixteen were women, (>50 years old), of all educational levels. Eleven of them said they where facing somatic health problems. Sixteen out of nineteen were first degree relatives (13 mother of patient) and were living in the same apartment with the patient. The mean duration of illness was 17.88 years and 7 (~ 37%) of them had no other person to help them, than close family members (eg. grandparents). All patients (most of them between 30-40 years of old) were suffering from disorders such as schizophrenia and bipolar disorder.

Conclusion: The family of the mentally ill has to carry a lifelong and hard responsibility. This is very often in the hands of one person, usually old or medically disabled. This makes the burden and the stress quite intolerable. Furthermore one must consider that the patient's care is endangered in case of loss or disability of the caregiver. The need for social support is demandable, for the wellbeing of patients and their families.

11. Konstantinos Paraschakis
12. Alexandros Gerontas
13. Christos Garnetas
14. Konstantinos Kontis

Aim: To estimate the degree of treatment compliance among psychiatric outpatients and the possible determining factors.

Methods: During a study concerning the compliance of mentally ill patients to the drug therapy, 73 patients (41 male, 22 female), of all ages and all educational levels, that come to the outpatient clinic for their scheduled appointment (21 persons with anxiety and mood disorders and 52 with bipolar or psychotic disorders), were given a questionnaire about their therapy.

Results: About 45% of the patients were exactly aware of their illness, 42% knew they suffered from "psychotic disorder" in general. The rest 13% did not know the reason for taking therapy. Among patients, 88% knew their drugs and dose, 6.5% knew only the dose and 5.5% did not know anything about their drug therapy. From 73 patients, 66 were satisfied with their drug therapy. Although doctors and parents encouraged the patients to comply with the medication, the latter sometimes received contradictory advice from friends, children and spouses. 33% of those asked, reported not following the medical instructions and having omitted 1-8 dosages during the last month, because of adverse effects, practical reasons or refusal of illness.

Conclusions: The 1/3 of our patients are not compliant to therapy. Moreover a fairly high percentage of psychotic patients ignore their exact diagnosis because of fear of stigma and psychiatrists' difficulty to explain the diagnosis to patients. Immediate social environment influences strongly the treatment compliance.

SHELTERING GROUP FOR DRUGS AND ALCOHOL DEPENDENTS: AN INSTRUMENT TO IMPROVE TREATMENT COMPLIANCE

INSTITUTIONS
1. Candido Ferreira Health Service, CAPS ad, Campinas, Brazil

AUTHORS
1. Sara Sgobin, DR, MD, sara.sgobin@gmail.com
2. Claudio Banzato
3. Karina Dinis
4. Sander Albuquerque
5. Clayton Santos

Noncompliance is a major problem in the treatment of substance dependent patients, seriously threatening its effectiveness. This work describes an intervention tool aimed at raising the compliance in outpatient treatment with substance dependence. The concept of sheltering implies an open door policy and provision of assessment to all patients who seek treatment. The scope includes listening to the patients' complaints, evaluating the resources that are necessary to manage each individual case, and setting a strategy for the therapeutic approach. Besides that, it reinforces the link with the patient, which is the most important factor in compliance.

Method: Descriptive study. Patients seen by the first time at an outpatient facility were evaluated and those who met the DSM-IV substance abuse and dependence criteria were referred to the sheltering groups. These groups are open, with six to eight patients, with one-hour duration, and are offered two times a day to facilitate the access. After about four sessions, the patient is usually referred to a case management team to elaborate an individual therapeutic project.

Discussion: Six months after the sheltering groups start being offered, a significant compliance improvement was noticed by the team. The sheltering group was also perceived as a useful approach for a comprehensive assessment of the patients, which reflected in a better tailored treatment plan. An open door policy and a flexible sheltering group schedule may improve the patient access to the treatment. Consecutives encounters with different team members possibly facilitates the link between the health service and the patients.

Aim: The aim of this study was to assess psychiatric morbidity among a group of Iranian psychiatrists.

Method: Authors sent the 28-item general health questionnaire (GHQ-28) to 87 psychiatrists, who were randomly selected from the list of Iranian Psychiatric Association. In addition, demographic data such as age, sex, marital status & self-reported history of mental illness were also inquired.

Results: Analysis of the data showed that 12.6% of psychiatrists gained a score above the cut-off point of 6 in GHQ-28 (using bi-modal scoring system) and there was a negative correlation between age and the GHQ score. However, applying the likert scoring system showed that 33.7% of the participants had a score above the mean. No significant difference was found across gender. According to psychiatrists’ self-report, 22.6% believed to be affected by some kind of psychiatric disorder, while just as few as 3.8% of them thought of having it before entering psychiatry as their career.

Conclusions: Relatively high rates of psychiatric morbidity and emotional disturbance were found among participants, yet mental health profile of Iranian psychiatrists was far better than the general population. Increased self-perception of psychiatric disorder after entering professional career needs to be further investigated.

Introduction/Objectives: The World Health Organization defines health as a state of complete physical, mental, and social well-being. Mental health is defined as the successful performance of mental functions, resulting in productive activities, fulfilling relationships, and the ability to adapt to change and cope with adversity. The aim of this study is to identify the mental health needs of Hamedanian people.

Methodology: This was a descriptive cross-sectional study. The participants consist of 1300 individuals who were selected by stratified sampling. A 30 item questionnaire was used to gather data from the sample. It consisted of three parts: A - demographic factors B - questions related to mental health service delivery C - questions related to mental health needs.

Results/Conclusions: The participants’ characteristics were: age between 14-65 years, 50% men and 53% married. Most had completed elementary education. Results showed that the Hamedan city people believed that mental health services are inadequate (45%), they did not access services near their home (74%) and media information about services was poor (34%). The expressed needs of people were: mental health education (72%), established mental health centers in schools and factories (<50%) and expanding the comprehensive mental health centers in the city (58%). The paper provides a rationale for providing mental health service delivery that are easily accessible, to promote mental health. Mental health programs should be planned after assessment and identification of social needs regarding the same.

3. Jiaru Lin, Ms., MS

People with depressive disorders tend to dysregulate their emotions, eg, excessively ruminating as well as avoiding negative emotions. Research showed that improving emotional skills helps emotional processing and adaptation. Besides, recent literatures of positive psychology indicated that positive emotions are conducive to enhancing individuals’ emotional competence and well-being. The purpose of the present study was to investigate effects of emotion-focused group treatment programs for depressed patients. The treatment groups were designed to enhance three emotional competences: emotion awareness, emotion regulation, and emotion reflection, and to foster a view that emotions contain adaptive information to utilize for growth as well. Furthermore, a focus on positive emotions was added in the positive emotion treatment condition. A 2 (pretest vs. posttest) x 3 (positive emotion vs. non-positive emotion vs. control group) factorial mixed design was used. There were 22, 24, and 15 patients in each group. It was found that patients who received group treatment with positive emotion enhancement showed significantly better results than the other two groups, both in symptom reduction and emotion competence improvement. The results indicated that better emotional processing indeed led to better adaptation. In conclusion, interestingly, a focus on positive emotions turned out to be an important facilitative change factors for depression.

3. Vlado D Skakic, Dr, MD, skaka@beotel.net

The authors reviewed the diagnoses from all inpatient psychiatric consultations conducted by psychiatrists during 12 months, from October 2006 to October 2007 (N=887) at the Clinical Center Nis, in southeast part of Serbia. Diagnoses were classified according to ICD-10 Classification of Mental Disorders. More than one psychiatric diagnosis was given in high percent of consultations. The group of patients seen by the consultation psychiatrists was 51.5% male. The most frequent diagnosis groups were organic mental disorders (20.5%, chronic, 12.08% acute), mental and behavioral disorders due to psychoactive substance use (13.6%, alcohol dependence prevalent-86%), and stress related disorders (12.1%) associated with suicidal attempts (9.1%). Psychosis, as psychiatric diagnosis, was present in 7.5% and psychosomatic syndromes was placed in 0.6% only. The most number of psychiatric consultations was carried out in Toxicology Clinic (168), Neurology Clinic (155) and Surgery Clinic (152). Repeated consultations were in low percent. The requirement for urgent consultations was found in about 26%. Psychosis, delirium, suicidal attempt, agitation, depression, anxiety and hallucination were the most frequent reason for urgent consultations. We found that cognitive disorders, substance use disorders and suicidal attempts were major diagnosis groups encountered in consultation psychiatry. Psychotherapy, psychosomatic aspects and patient different reactions on somatic illness were not the main part of consultations. This way of psychiatric consultation is insufficient treatment of medical and psychological problems of hospital inpatients. Therefore, further clinical practice must better integrate consultation-liaison psychiatry with psychosomatic and behavioral medicine, as well as primary care and general hospital psychiatry.

THE ROLES OF A PSYCHIATRIST (AN EXPERIENCE FROM A COUNTRY IN TRANSITION)

INSTITUTIONS
1. Health Center Valjevo, Department of Psychiatry, Valjevo, Serbia and Montenegro
2. Institute for Mental Health, Belgrade, Serbia and Montenegro
3. Psychiatric Clinic, Clinical Center Kragujevac, Kragujevac, Serbia and Montenegro

2. Dusica Lecic Tosevski, Dr., MD, PhD
3. Slavica Djkic Dejanovic, Dr., MD, PhD
4. Tomislav Gajic, Dr., MD, MSc
5. Zorka Lopicic, Dr., MD, PhD
6. Goran Mihajlovic, Dr., MD, PhD

The basic role of a psychiatrist is a helping one. This role is just one among many a psychiatrist in a transitional country has to play. Clinical work, the essence of our profession, maintains or even increases its importance, but other challenges appear. The reform of psychiatry, moving to community mental health, with very important roles for others, and strengthening of primary care, could present a threat to psychiatric community. Nevertheless, there are still a lot of things that psychiatrists “have to do”. Role of scholar/researcher opens up as an attainable possibility. But could it be a sort of “internal emigration” as well? Numerous changes in more open society create a need for more psychiatric expertise in different areas. Media are constantly looking for provocative issues, and mental health being one of them, makes a psychiatrist an excellent participant in TV shows. Judicial system is another user of psychiatric expertise, more and more often as times go by. Does this mean our patients commit more crimes? Or people just think more about mental health problems? Psychiatrists appear as managers/leaders in health institutions, or become highly valued members of management teams. Is this appreciation of our knowledge and skills or unrecognized need for help in burn out syndrome? Or is it an idealization of our powers? These and some other roles are those we are playing and living in the transition. This poster aims to initiate further discussion about it.

A MENTAL HEALTH ASSESSMENT AND SUPPORT TEAM FOR COMMUNITY ELDERS IN A SCOTTISH HEALTH REGION

INSTITUTIONS
1. NHS Fife, Department of Psychiatry, Cupar, Fife, Scotland, United Kingdom
2. Fife Council, Social Work, Cupar, Fife, Scotland, United Kingdom

AUTHORS
1. Gary S Stevenson, Dr, MRCPsych, MPhil, garystevenson@fife-pct.scot.nhs.uk
2. Heather Ewing, Mrs
3. Joyce Keith, Mrs, RMN

Background: The ‘2005 National Framework for Service Change in the National Health Service (NHS) in Scotland’ promoted the need for NHS service delivery in local communities rather than in hospitals, and to develop a systematic approach for the most vulnerable (especially older people) with long term conditions with a view to managing their conditions at home or in the community and reducing the chance of hospitalization. This combined with the recognition of an aging population encouraged service redesign in a Scottish health region with the focus on community assessment of older people with mental health needs.

Aims: To establish and assess the functioning of a joint Health and Social Services enhanced assessment and support team (EAST) for community-dwelling elders with significant mental health needs living in a Scottish health region, and to determine the impact of this team on mental health hospital services.

Methods: Prospective three-year data collection of local service activity involving EAST, and both inpatient and day hospital facilities for older adults with mental health problems.

Results: EAST assessed 111 patients during the study, 83% with a diagnosis of dementia. The mean duration of assessment was 6 weeks with 9% of patients receiving an overnight home assessment and 6% requiring hospital admission. Overall there was a substantial reduction in utilization of both acute admission beds and day hospital placements.

Conclusions: Multi-agency community assessment of older adults with mental health problems can be addressed effectively without recourse to hospital admission, which may allow resource release for further service developments.

A PSYCHIATRIC INTENSIVE CARE UNIT (PICU) FOR OLDER ADULTS IN A SCOTTISH HEALTH REGION

INSTITUTIONS
1. NHS Fife, Department of Psychiatry (Older Adults), Cupar, Fife, Scotland, United Kingdom

AUTHORS
1. Gary S Stevenson, Dr, MRCPsych, MPhil, garystevenson@fife-pct.scot.nhs.uk
2. Muhammad A Khan, Dr
3. Nagarajan Perumal, Dr, MRCPsych
4. Greig Calley, Mr, RMN

Background: A number of definitions for 'psychiatric intensive care' exist but generally they detail care in a multidisciplinary, highly staffed, and often secure, unit for persons with mental disorder and associated behavioural disturbance. The role of psychiatric intensive care units (PICU) is well established for the general adult psychiatric population, but these units are often less suitable for older adults. A dedicated PICU for older adults in a Scottish Health Region serving a population of 350,000 was established in 2001 to deal primarily with an increase of behaviourally challenging demented male patients in the psychogeriatric admission wards of that region.

Aims: To detail patient characteristics and outcomes of admission to the PICU for older adults in a Scottish Health region.

Method: Prospective survey of admissions to the PICU from January 2006 until August 2007, using routinely collected data.

Results: 25 male patients, mean age 74 years, were admitted during the survey, with 52% detained under Mental health legislation. The main transfer reasons were resistive behaviours and persistent physical aggression. The majority (32%) of patients had a primary diagnosis of Alzheimer's dementia, 20% with vascular dementia. The average mini-mental state score was 15/30, and the mean duration of patient stay in the PICU was 54 days, with 84% of admissions discharged from the unit during the evaluation period.

Conclusions: A regional psychogeriatric intensive care unit can serve a useful function in the management of disturbed elders who are otherwise difficult to manage within existing psychogeriatric acute admission wards.

CLINICAL UNCERTAINTY AMONGST SCOTTISH PSYCHIATRISTS ABOUT CRITERIA FOR NATIONAL HEALTH SERVICE CONTINUING CARE

INSTITUTIONS
1. NHS Fife, Department of Psychiatry, Fife, Scotland, United Kingdom
2. NHS Fife, Department of Public Health Medicine, Fife, Scotland, United Kingdom

AUTHORS
1. Gary S Stevenson, Dr, MRCPsych, MPhil, garystevenson@fife-pct.scot.nhs.uk
2. Agnieszka Philipson, Dr, MRCPsych
3. Gordon McLaren, Dr

Background: The Scottish Office Department of Health issued guidance in 1996 on 'National Health Service (NHS) Responsibility for Continuing Health Care' which is provided free of charge to patients whose complexity, nature or intensity of care needs (medical, nursing or other clinical) are sufficient to fulfil certain criteria. Due in part to differing NHS guidance in England, there has been increased complaints to Health Boards and the Scottish Public Service Ombudsman (SPSO) about patients deemed not to fulfill the Scottish criteria.

Aims: To establish the level of knowledge amongst experienced psychiatrists about current Scottish regulations on NHS Continuing Care.

Methods: Following a pilot survey, a modified postal questionnaire comprising 19 structured questions was sent to 134 psychiatric consultants and specialist trainees in south-east Scotland in mid-2007, with a reminder to non-responders.

Results: A 54% response rate increased to 66% following reminders. Of these, 82% were consultants and 88% had clinical responsibility for inpatient care within the past decade. Only 24% of respondents were aware of the current Scottish guidance for NHS Continuing Care, with only 14% aware of the actual 1996 document. There was uncertainty regarding responsibility for both discharge and appeal processes although 8% had been involved with a formal complaint relating to NHS Continuing Care and 10% involved with the SPSO. Conclusions: Clinical uncertainty abounds regarding the criteria in Scotland for NHS Continuing Care, despite guidance being issued over a decade earlier. There is urgent need for raising awareness of the criteria amongst relevant practising clinicians in Scotland.

5. Gilda Pulcherio¹, Mrs., MD

Objective: Picked up from a larger research, this study aims to verify what kind of concepts are use by women and men during the life spam to indicate what femininity/masculinity are.

Method: The participants completed a questionnaire with demographic data and open questions about femininity and masculinity. SPSS to get statistical analyses

Results: Women mainly evaluate Femininity through behavior (30.8%), personality characteristics (26.9%), and sex-roles (16.7%). Men mainly evaluate Femininity through Personality Characteristics (38.5%), behavior (32.7%), and sex roles (15.4%). Women mainly evaluate Masculinity through Personality characteristics (31.2%), behavior (23.4%), and sex-roles (14.1%). Men mainly evaluate Masculinity through Behavior (36.9%), Personality characteristics (23.1%), an "tastes" (10.8%). The major differences between women and men considering Femininity and Masculinity are inside each larger category.

Conclusion: Women and men evaluate Femininity and Masculinity by the same categories of analysis, with an exception of Masculinity by men, that include "tastes" (to like Soccer, beer, etc.), but inside each category differences about Femininity and Masculinity are seen as big ones.

Treatment of patients with schizophrenia in community considered different programmes with the aim to achieve as high as possible level of resocialization and rehabilitation (1, 2). The aim of this study was to analyse the efficiency of home treatment concerning functional of patients in community.

Method: In this research analysed were 40 patients with schizophrenia treated in mental health centres with home treatment program concerning social functioning and structure of daily activities. For the purpose of this research used was a social functioning scale which was applied in the beginning of the inclusion in home treatment and after 12 months. Sociodemographic data and data about structure of daily activities were gathered on the basis of medical data from centres for mental health.

Results: The average age of patients questioned was 53.5±13.6. Out of total number of patients, 34 patients lived with some family member, while six lived alone. According to structure of daily activities eight patients were most of the day passive. Social functioning in 23 patients was significantly better (p<0.05) after 12 months of home treatment significantly.

Conclusion: With a home treatment of patients with schizophrenia much a higher level of social functioning has been achieved.

SELF HELP SUPPORT GROUP FOR MUMBAI MUSLIM WOMEN

INSTITUTIONS
1. Trellis Family Centre, Psychiatry, Mumbai, India
2. SAARC Association of Young Psychiatrists & Trainees, India
3. Indian Association of Young Psychiatrists & Trainees, Mumbai, India
4. Indian Psychiatric Society, India

AUTHORS
1. Ruksheeda N Syeda*, Dr, DPM, ruksheeda@yahoo.co.in

Structurally adjusting countries like India, populated with ethnically and culturally diverse communities face their own unique mental health challenges. The evolving urban Muslim woman, facing systemic issues of traditional familial framework, limited resources, constricted employment, social exclusion is also often a victim of stereotypes and ignorance. All these factors and more contribute to the everyday stress level which may lead to psycho-social distress and illnesses. Mental health services can be complimented by human services. This led to the conception of a self help support group (SHSG) for Muslim women as an initiative towards emotional well-being of this minority strata of society. Women from the community with an insight into their own mental health & commitment towards it, came together for this endeavor. Other women of their acquaintance (16 years & above) were invited by them which included professionals, students & stay at home mothers.

Methodology:
Recruitment Process - word of mouth.
Participants - The group features were homogeneity with regards to community, gender, age, ideology.
Group Work - A holistic approach towards promotion of mental health, open - ended and fluid membership.
Challenges & Limitations - To be discussed.
Method - A semi-structured questionnaire was designed to examine the experiences with and perception of the group; and the subsequent impact on the individual.
Findings - Aims, working, success & failures of the group work are assessed. Emerging themes are examined through an interpretive paradigm (Denzin & Lincoln 1994; Flick 1998).

This paper will discuss the evolution of the 2 year old SHSG of Muslim women.

3. Silvia Rajchenberg¹, Dr., MD
4. Gabriel Brenner¹, Dr., MD
5. Fabio Celnikier¹, Dr., MD
6. Roberto Sivak¹, Dr., MD

It has been shown that extreme distressful situations have a profound impact on every human being, such as the observed after the Holocaust (shoah) perpetrated by the Nazi regime during WWII, which represented a breaking point in the lives of those who went through these traumagenic experience. In this regard, many Holocaust survivors managed to rebuild their lives in a resilient manner, while many others did not succeed to recover, therefore living an existence of trauma and depression. The aim of our work is oriented to study a potential profile of resilient subjects as it is expressed in a population of survivors as well as their offspring. Therefore, we performed both, a cognitive evaluation of some volunteer subjects, and an exhaustive review of descriptions registered in the bibliography. The possibility to define a resilient profile may lead to the understanding of cognitive and neurobiological features of resiliency, and therefore, to the development of more successful coping strategies and more effective therapeutic approaches to help people affected by traumagenic situations, including psycho-social conflicts and bio-ecological disasters.
THE EFFECT AND EVALUATION OF A MENTAL HEALTH EDUCATION PROGRAM IN JUNIOR HIGH SCHOOL STUDENTS FOR EARLY INTERVENTION AND PREVENTION: PROLONGED EFFECTS ON HELP-SEEKING BEHAVIOR

Aims: Mental maladjustments are frequently seen in junior high school students in Japan. However, adolescents tend not to seek help because of poor understanding and negative image of mental disorders and consultation. The aim of this study was to evaluate the effects of a mental health education program on distressed students' help-seeking behavior after one year.

Subjects and Methods: Subjects were 167 first-year students (12 or 13 years old) from 3 junior high schools in Japan. Subjects were divided into an intervention group and a control group. The education program consisted of 4 lectures and a visit to one of several psychiatric institutions and was applied to the intervention group. Subjects of both groups were assessed before and after intervention using questionnaires based on the Attitudes towards Seeking Professional Psychological Help Scale (ASPH), the Hope of Consultation Attitudes Scale (HCAS), as well as knowledge and need for consultation scales of our own design. We used two-way analysis of variance and chi-square test to evaluate help-seeking behavior.

Results: Knowledge of mental disorders and understanding the need for consultation was still significant after one year. ASPH and HCAS indicated small to moderate effectiveness. Intervention group students in distress tended to seek help through their networks compared with the control group.

Conclusions: The effect of our mental health education program continued to positively affect help-seeking behavior after one year.

PUBLIC PERCEPTION OF MENTAL HEALTH SERVICES IN EARTHQUAKE AFFECTED AREA IN KUTCH, INDIA

INSTITUTIONS
1. hospital for mental health, Bhuj, India
2. IHBAS, Psychiatry, Delhi, India
3. ICMR, Delhi, India

AUTHORS
1. Mahesh P Tilwani, Dr., MD, Drmttilwani@rediffmail.com, 2. N. G. Desai, Dr., MD, ngd1955@rediffmail.com
3. D. K. Gupta, Dr., MD, 4. B Shah, Dr., MD, 5. A Nayak, 6. Prakash P. Shukla, Mr., Hotlion2001@yahoo.com
7. M Akbari, Mr., 8. S. Pandey, Dr., PhD

Objectives: To assess the public perceptions about availability and usefulness of mental health services in the earthquake affected area of district Kutch of Gujarat, India.

Methods: Two hundred fifty people identified in an epidemiological study on the mental health consequences of earthquake in Kutch region of Gujarat in 2001 as suffering from various psychiatric illnesses were included in the study. They were interviewed by using qualitative research technique in-depth interview to find out their perception about availability of mental health services in the aftermath of disaster and usefulness of these services. Conclusion:- most of the respondents were not aware about the availability of mental health services in their area.

Results: Most of the patients were not been aware of available mental health services in their area and only few of them reported using these services. This perception was found to be in variance with the information from secondary data sources about many of the organizations and agencies reportedly working in this area to provide psychosocial care and mental health services.

Conclusion: Various agencies working for delivery of mental health services in disaster affected areas need to ensure that services provided by them have wider accessibility, get adequately utilized and recognized by the target population to maximize the impact of these services.

3. Svetlana Alshevskaya

The accident on Chernobyl NPS doesn’t have analogue in the world in scale and character. Many aspects of Chernobyl accident have been suggested to cause mental disorders, stress, and anxiety in the population.

Aim/Objectives: The aim of this study was to examine the signs of psychological distress and its reasons in teenagers residing in regions contaminated with radionuclides.

Methods: 138 teenagers (13 - 16 years) residing in contaminated regions had been examined with Spilberger’s State Trait Anxiety Inventory, Reeder Inventory, SCT (Sentence Completion Test). We used SCT created by prof. Tatara M. (Japan) for children and adolescents suffered from Chernobyl accident.

Results: No connection between psychological distress and density of radionuclide contamination has been revealed. 4.7% of the adolescents even don’t know what radiation is, 4.7% consider it as poison, 3% as microbes. 73% of teenagers characterise it as contamination, disease, death, horror etc. 20.6% of adolescents can say correctly that Chernobyl is the town, where accident on NPS had been occurred, but 68% of teenagers consider it as pain, tragedy, horror, “everything is forbidden” etc. 65% of teenagers feel severe distress in connection with there school study not depending whether it is successful or not. 10% develop distress in their families. High levels of trait and state anxiety have been found more frequently in girls.

Conclusions: Psychological distress in teenagers residing in contaminated regions depends on sex, school study, family and attitude to radiation.

ABOUT PSYCHOANALYTIC DISCOURSE IN TURKEY

INSTITUTIONS
1. Istanbul University, Psychology, Istanbul, Turkey
2. Istanbul University, Psychology, Istanbul, Turkey

AUTHORS
1. Bilge Tuncelli, Ms, bilge_tunc50@yahoo.co.uk
2. Oya Celik, Ms, oyacelik@yahoo.com

AIMS: The aim of this study is, to understand information about the content of daily psychoanalysis knowledge. Psychoanalysis, which is one of the important theories of developing psychology and modern psychiatry, has been taking a vital place in Turkey for 15-20 years. Thus, it is possible to say that, there is a discourse about psychoanalysis in the society.

METHOD: In this study, focus group technique is utilized in order to inquire daily usage of psychoanalytic discourse. Focus Group Technique is a method that a group of 6-10 individuals gathered to discuss a particular topic under the direction of a moderator, recording this discussion and analysing the recorded data (Kreuger, 1998). Data, that produced by focus group technique, will be assessed by discourse analysis. Discourse analysis is a kind of analysis technique, that is suggested by Discursive Psychology and considers some fields; such as ethnomethodology, rhetoric, philosophy of language, conversation analysis, post-structuralism, sociology of knowledge, while having an evaluation (Edwards, Potter, 1992, Burr, 1995). The analysis of the groups are still in progress. After this stage, produced data will be assessed by discourse analysis.

RESULTS: The results are being assessed.

ADAPTATION AND ACCULTURATION OF A QUALITATIVE RESEARCHER IN A RELIGIOUS INSTITUTION TO FUTURE DATA COLLECTION FROM EX-HOMELESS ALCOHOLIC SUBJECTS IN BRAZIL: A REPORT OF FIELD EXPERIENCE

INSTITUTIONS
1. State University of Campinas (UNICAMP), Department of Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas, Brazil

AUTHORS
1. Milene Pescatori Packer¹, Mrs., mavami@terra.com.br
2. Egberto Ribeiro Turato¹, Dr., PhD, erturato@uol.com.br

Aim: To discuss methodological strategies for adaptation/acculturation of a researcher in religious institution that takes in homeless alcoholics in order to perform later a qualitative investigation about psychological meanings about their institutionalized lives.

Method: Using field notes¹, it was a preliminary investigation, interacting progressively with the staff and seeking to hear freely institutionalized individuals' life stories².

Results: It was possible to observe dynamic aspects of the non-scientific institution and to realize that interviewed subjects do not live in community so easily. Religious institution - which welcomes the homeless who express wish for leaving the streets - manages to get an appropriate care. Entry of researcher in field and achievement of the staff were up to establish a satisfactory rapport between the first one and possible informants, as a facilitator for accurate data collection and like this to maximize its methodological validation.

Breaking paranoid fantasies is crucial.

Conclusion: Initial barriers found in this setting must face subtly by the researcher. This report creates space for discussion on processes of adaptation/acculturation for qualitative researchers in non-academic institutions, usually not get used to develop research activities. The adequate acculturation allowed the progress of project in a post graduation course in mental health area.

BIOPSYCHOSOCIAL DESCRIPTION OF ADAPTIVE ASPECTS PRESENTED BY INDIVIDUALS WITH AMPUTATION DUE TO VASCULAR DISEASE OR TRAUMA IN A UNIVERSITY HOSPITAL FROM BRAZIL

INSTITUTIONS
1. State University of Campinas (UNICAMP), Department of Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas SP, Brazil

AUTHORS
1. Fabiana Hisako Sekiya¹, Mrs., fabiana_sekiya@yahoo.com.br
2. Egberto Ribeiro Turato¹, Dr., PhD, erturato@uol.com.br
3. Claudinie Jose Gomes Campos¹, Dr., PhD, cjcampos@fcm.unicamp.br

Aims: To focus on the meanings presented by individuals with Acquired Physical Disabilities about their health condition. The authors purposed to analyse the adaptive biopsychosocial aspects presented by people who have had one of their lower members amputated as a result of a disease or trauma.

Method: From clinical-qualitative methodology¹ using semi-directed interviews with open-end questions² applied to a sample composed by ten individuals, group closed by saturation technique, under treatment at the Prosthesis and Orthosis Unit of a university hospital in the São Paulo State, Brazil. The data collected was analysed by means of the Thematic Contents Analysis Method.

Results: After three-floating re-readings of interviews, nine categories was identified concerning these themes: the event as an inevitable and unexpected situation, several reactions between amputees due to disease and those due to trauma, peculiar psychological mechanisms of defence and adjustment, ghost pain, ghost feeling and pain in the stump, complaint about difficulties in locomotion and physical dependency, discrimination and stigma, additional relationships with family members and friends, low socio-economic status to acquisition of prosthesis, amputation as a social issue and spirituality.

Conclusion: It is crucial that the processes of psychosocial rehabilitation must be continuous, starting up ever in preparation to the surgery and lasting until closer to a possible full independence of the amputated individuals.

MEANINGS OF THE HISTORICAL PROGRESS IN MEDICAL-PSYCHOLOGICAL APPROACHES TO HIV/AIDS PATIENTS ATTRIBUTED BY PHYSICIANS AND NURSES WORKING IN A UNIVERSITY DAY-HOSPITAL IN ITALY: A QUALITATIVE STUDY

INSTITUTIONS
1. State University of Campinas (UNICAMP), Faculty of Medical Sciences - Laboratory of Clinical-Qualitative Research, Department of Medical Psychology and Psychiatry, Campinas, Brazil

AUTHORS
1. Egberto Ribeiro Turato¹, Dr., PhD, erturato@uol.com.br
2. Amilton dos Santos Jr.¹, Dr., amilton1983@yahoo.com.br

Aims: (a) initial moments of approaching HIV/AIDS patients, many data raised in anamnesis would have served to satisfy the professionals’ psychological curiosities; (b) after the impact of its appearance, medical sciences would have wandered off the valorisation of its historicizing aspect.

Method: qualitative study with semidirected interview. Sample achieves saturation with five professionals, working at least ten years with HIV/AIDS, in sequence of another investigation with patients at the General Hospital of Padua, Italy. Content analysis, highlighting selected speeches, was discussed to develop two present topics.

Results: Anamneses, in initial moments, seemed not only to explain the “chain of facts” linked to epidemiology and clinics, but they also sought to satisfy curiosities. Professionals had faced a “new old” population, which emerged with phenomena less usual in medical settings: certain affective-sexual behaviours and use of drugs by many social groups. Anamneses, nowadays, are centred on physical manifestation, because they shape exemplarily biological facts. Ill person’s non-biological dimensions were left to the “speculative” fields. Health scientists fitted the AIDS under positivist paradigm.

Conclusions: although the HIV/AIDS had represented a deleterious event, its appearance has contributed to bring up the discussion about important human hidden behaviours. Health professionals should retake detailed anamnestic elements, valuing symbolic meanings to improve professional-patient relationship and to increase treatment adherence.

MEANINGS ON BODY IMAGES AND SCALE OF PERSONAL VALUES ATTRIBUTED BY HIV/AIDS PATIENTS OF A UNIVERSITY DAY-HOSPITAL IN ITALY: A QUALITATIVE STUDY

INSTITUTIONS
1. State University of Campinas (UNICAMP), Department of Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas, Brazil

AUTHORS
1. Egberto Ribeiro Turato1, Dr., PhD, erturato@uol.com.br
2. Amilton dos Santos Jr.1, Dr., amilton1983@hotmail.com

Aims: to discuss if the sick persons, in relationship with themselves and with others, would search peculiar ways to deal with their negative feelings toward the progress that damages their global integrity; and if even faced with the eventual evidence of both the clinical aggravation and the worsening of their prognoses, the patients could not have their lives gravitating around the concerns with this disease in a way so important

Methods: qualitative with semidirected interview, open-ended Questions. Sample composed by 12 patients from the General Hospital of Padua, Italy, using saturation technique.

Results: an anxious search for the own image in front of mirror becomes significative comparing themselves with images in old photographs. In the relationship with others, a search of the own image is also found through the persons’ attitudes; there are patients whose lives gravitated more around other personal concerns, such as love, work or financial problems.

Conclusions: Health professionals must be careful regarding the concerns of their patients’ self concept: words and looks are important to reconstruct their psychological world. Explaining common sense ideas can be a risk. Patient-centred care can disrespect ill persons’ scale of values, given that ill persons can see HIV, at present, as a non-stigmatizing problem.

PSYCHOCULTURAL MEANINGS OF THE FEMALE URINARY INCONTINENCE - A LITERATURE REVIEW

INSTITUTIONS
1. State University of Campinas (UNICAMP), Department of Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas, Brazil

AUTHORS
1. Rosangela Higa1, Mrs., MD, rosangelahiga@bol.com.br
2. Maria Helena Baena de Moraes Lopes1, Dr., PhD, mbbaena@fcm.unicamp.br
3. Egberto Ribeiro Turato1, Dr., PhD, erturato@uol.com.br

Objective: To identify studies about psychocultural meanings of life experience with urinary incontinence (UI) as reported by women.

Method: From the literature raised in databases (Medline, Pubmed, Medscape), studies that addressed the UI women's life experience were selected firstly by the title, and then by their content. After selective re-readings, articles got into groups according to three categories on experiences: age, religious/cultural patter and self-care.

Results: Symbolic aspects of UI to elderly women were more associated with ideas that it was an unavoidable phenomenon, as a result of advanced ages, and so described how a normal degenerative process. Among the younger and middle aged, it was seen as a social phenomenon not acceptable and a loss of body's healthy properties. In cultural-religious sub-group, psychosocial aspects for Western and Eastern women showed similarities feelings, such as shame, guilt and social isolation. Jewish and Muslim related stress due to need for a clean body to pray and it was relevant problem to take religious precepts up. Self-perception about their UI may lead to different levels of emotional disorder that interfere to seek treatment in order to maintain self-care.

Conclusion: Diversity of reported results seems associated to psychocultural meanings assigned to the female body, given that human meanings has an always-present polysemy. Female UI can generate suffering, and both the lack of correct information and eventual shame are perceived as barriers to the adequate self-care.

2. Egberto Ribeiro Turato1, Dr., PhD, erturato@uol.com.br

Objective: To discuss the psychological pregnancy experience as reported by women with sickle cell disease anaemia disease, given that this disease is the most common hereditary one in Brazil and it is a relevant public health problem. Women with sickle cell anaemia disease who are able to become pregnant are at increased risk of miscarriages and complications during the childbirth.

Method: Qualitative study1 with nine women with ages varying from 19 to 35 and gestation age ranging age from 16 to 30 weeks. Their follow up was done at the Clinic of High Risk of the General Hospital of the State University of Campinas, Brazil. Semidirected interviews with open-ended questions were conducted, recorded, transcribed, underwent qualitative content analysis and interpreted in light of psychodynamic framework.

Results: For the present presentation, two emergent categories were relevant: (a) meanings of maternity for those women; and (b) perceptions and the handlings of the disease implications in their daily lives2.

Conclusions: The discussion has suggested that in spite of the feelings of existential and psychological anguishes, that usually involve this kind of pregnancy, as wells as the awareness of possibilities of clinical complications for women as mothers and/or for babies, there was still a reported strong desire of experiencing motherhood.

PSYCHOSOCIAL ADAPTATION MECHANISMS USED BY WOMEN WITH TURNER SYNDROME IN BRAZIL: A QUALITATIVE STUDY

INSTITUTIONS
1. State University of Campinas (UNICAMP), Department of Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas SP, Brazil

AUTHORS
1. Vera Lucia Soares Chvatal1, Dr., PhD, verachvatal@gmail.com
2. Fatima Böttcher-Luiz1, Dr., PhD, boluigi@terra.com.br
3. Egberto Ribeiro Turato1, Dr., PhD, erturato@uol.com.br

Objective: To outline the psychosocial adaptation mechanisms used by women with Turner Syndrome (TS) built when confronted with diagnosis of this illness, seen in an outpatient service.

Method: Qualitative research was particularly suitable for this study given the exploratory nature of this work. Semidirected psychological interviews were administered to 13 women from the Centre of Integral Attention for Woman's Health, State University of Campinas, São Paulo State, Brazil. Data collected was submitted to Qualitative Content Analysis and thus categorized: (a) type of reactions in the face of the diagnosis; (b) the illness experienced as a social stigma; (3) types of psychosocial mechanisms of adaptation. Afterwards this data was interpreted in accordance with psychodynamic reference framework.

Results: After free-floating rereadings of interviews, the following topics emerged: relevant psychosexual conflicts, difficulties in interpersonal relationships, jealousy, feelings of impotence; presence of mechanisms of repression, negation, low self-esteem, and sublimation.

Conclusion: Women with TS have to deal with organic and psychological intermingling factors regard to their illness that brings major suffering and frequently makes great difficulty of a healthy social insertion. Findings of this research became useful for a psychological approach complementally to the routinist medical healthcare considering TS patients.

WHAT DOES BARIATRIC SURGERY REPRESENT MENTALLY TO OPERATED WOMEN ONE YEAR EARLIER? A QUALITATIVE STUDY IN BRAZIL

INSTITUTIONS
1. State University of Campinas (UNICAMP), Department of Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas, Brazil

AUTHORS
1. Ronis Magdaleno Jr1, Dr., ronism@uol.com.br
2. Egberto Ribeiro Turato1, Dr., PhD, erturato@uol.com.br

Objectives: To understand what happens emotionally to women who undergo bariatric surgery and how these events relate to the genesis of the eventual psychiatric disorders.

Method: Clinical-qualitative, a particularization of humanistic methods applied to the health field.

Results: Desire for a beautiful body and acceptance of the woman socially are the major motivations for a surgery. A hypomanic phase called “the honey moon with the surgery” follows. Frustration of that expectation may cause depressive disorders. Anxiety and depressive disorders are frequent due to the sensation of failure, and can lead to suicidal ideation. Surgery prevents ingestion of large amounts of food, but it does not solve compulsive behaviour, which may lead to psychiatric disorders like nervous anorexia, bulimia or other compulsive behaviours, such as alcoholism. Surgery becomes an obsession and afterward it is replaced by a reparative plastic surgery. Patients that succeed in maintaining weight experiment an increase of self-esteem and recuperate their identity, which protects them from mental disorders.

Conclusion: Bariatric surgery is a therapeutic resource that shall be used subjected to rigorous criteria, because it represents physical and psychological strain. Health team must be prepared to deal with the emotional complications that arise from the surgery. Psychotherapy is fundamental to a good long-term result. Understanding meanings of the surgery from the operated patients improves therapeutic results regarding the psychiatric disorders.

TOWARDS A PSYCHIATRIC POLICY FOR EAST-EUROPEAN COUNTRIES AND BALKANS

INSTITUTIONS
1. University of Medicine and Pharmacy, Clinic of Psychiatry, Craiova, Romania

AUTHORS
1. Tudor Udrisoiu1, Professor, MD, PhD, office@psycv.ro
2. Ion Udrisoiu1, Dr., MD, monarist@gmail.com
3. Dragos Marinescu1, Professor, MD, PhD, office@psycv.ro

The mental health policy and the reform of psychiatric services in our countries have encountered high difficulties, as well in their elaboration and particularly in their implementation. Basically, the problems in the region are alike: from legislation to infrastructure, from the lack of professionals to the reduced offer of services, from mentalities to severe financial limitations, from education to the general situation of health services.

In Romania, there are more plans than achievements so far. Psychiatry receives less than 3% of the global health budget, there are 0.5 psychiatrists, 0.2 psychologists, 2 nurses and 0.06 social workers for 10 000 inhabitants and the access to diagnosis and psychiatric care is reduced.

Considering the facts mentioned above and Romanian traditions, the "social model" implemented in developed European countries is not useful for us, both economically and culturally. Moreover the mental health promotion and community psychiatric services are based on antipsychiatry, marginalize the clinical psychiatry and do not offer a favorable cost-advantage ratio.

Based on internationally recognized documents, which gravitate around the "WHO European ministerial Conference on Mental Health", we will try to demonstrate that for Romania and probably for the whole region, the actual priority should be the elaboration and the systematic implementation of a "psychiatric policy" that lies upon the medical model.

Caring well all patients through a sufficient and various offer of services for secondary prevention, efficient rehabilitation programs and opportunities for addiction treatment, we could discuss realistically about the mental health policy.

ADAPTING ACT FOR USE AMONG HARD-TO-TREAT- PEOPLE IN A MEDIUM SIZE CITY IN HOLLAND

INSTITUTIONS
1. Reinier van Arkel Psychiatric Services, ‘s-Hertogenbosch, The Netherlands
2. Columbia University, Epidemiology Department, New York, United States

AUTHORS
1. Helga V. Saez1, Dr., MD, helgasaez@home.nl
2. Elie S Valencia2, Dr, JD, MA, esv1@columbia.edu

Objective
To adapt the Assertive Community Treatment (ACT) Model for use for use among hard-to-treat people with severe mental illness (SMI) in a medium-size mental health service area in The Netherlands.

Methods: Our adaptation does not include individual research assessments of clients in order to minimize their burden and maximize their participation in the services. It consists of three inter-related phases. Phase One includes: a) identification of 30 of the most difficult patients to treat for this trial, among long-term care clients (N: 820) of Renier van Arkel Psychiatric Services in s-Hertogenbosch; b) Collection of one-year Case Register data on participant’s service use and clinical and demographic variables prior to this trial. Phase Two includes: a) Provision of in-vivo training to a team to work with the ACT methodology; b) Assessing over a year the provision of ACT, including follow-up service use and data collection from charts on substance use and quality of life. In Phase Three, we adapt ACT for use in our area and produce an intervention manual based on our experience in this trial, collected data, and on our overall clinical and research experience with hard-to-engage populations.

Results: We successfully identified our target group, provided the team in-vivo training and the ACT service provision. Phase Three of the study is still being completed.

Conclusion: Initial assessments suggest that adapting an evidence-based intervention based on collection of clinical implementation data and non-intrusive collection of available service use and clinical variables data might be an useful method.

3. Philip George¹, Associate Professor, MMed(psy), philipgeorge_joseph@imu.edu.my

Aims/Objectives:
A cross-sectional descriptive study of homeless individuals in an Institution for the states of Wilayah Persekutuan and Selangor in Malaysia was conducted. The aims of this study were to examine the prevalence of psychiatric morbidity in these individuals and to study demographic and other factors associated with homelessness and psychiatric disorders.

Methods:
During the period of March 2005 to end of June 2005, 70 participants through universal sampling were recruited to participate in the study. Informed consent was taken and they were interviewed using SCAN and CISR.

Results:
The prevalence of psychiatric morbidity in the institution was found to be high with 30 percent of individuals suffering from psychosis and 40 percent of individuals suffering from various neurotic disorders. The education level was generally low. Psychotic illness was associated significantly with secondary education, poor social support and younger age group. Neurotic disorders were not significantly associated with other demographic factors.

Conclusions:
This is the first such study among homeless in Malaysia and shows that there is a high prevalence of psychiatric morbidity among the homeless. Mental health services are thus essential for this group.

TERMINATION FROM PSYCHOTHERAPY IN CANADA: PATIENT REASONS AND THEIR CORRELATES

INSTITUTIONS
1. University of Ottawa, School of Psychology, Ottawa, Canada

AUTHORS
1. Robin Westmacott¹, Ms., M.A., rwest023@uottawa.ca
2. John Hunsley¹, Dr., PhD, hunch@uottawa.ca

Although effective psychotherapies are available, nearly 50% of psychotherapy patients terminate psychotherapy early. Shorter treatment is sufficient for some patients who terminate early, but for others, it is likely insufficient for meaningful improvements. Reasons patients report for terminating may provide insight into barriers that limit the effectiveness of psychotherapy. Community surveys have examined mental health treatment dropout but no epidemiological research has examined patient reasons for terminating psychotherapy. The Canadian Community Health Survey in 2002/03 included data on past year psychotherapy use and 10 specific reasons why treatment ended. Proportions of respondents endorsing these reasons were compared across demographic, clinical, and service variables. 255, 202, 255, and 326 respondents stopped treatment with family doctors, psychiatrists, psychologists, and social workers, respectively. Overall, across providers, the following reasons for termination were reported: 43.0% indicated termination due to feeling better, 13.1% because treatment was completed, 14.9% reported it was not helping, 7.0% thought problems would get better without help, 4.7% could not afford treatment, 0.4% were embarrassed to continue, 5.5% wanted to solve problems on their own, 1.9% stopped due to circumstantial barriers, 4.2% because the service was discontinued, and 7.1% were not comfortable with the professional's approach. Knowledge of these correlates can contribute to practitioners' awareness of which patients are more likely to terminate for which reasons.

COMPARISON OF PUBLIC’S STIGMA ATTITUDE BETWEEN AIDS AND SCHIZOPHRENIA

INSTITUTIONS
1. E-DA Hospital, Department of Psychiatry, Kaohsiung, Taiwan Republic of China
2. I-SHOU University, Kaohsiung, Taiwan Republic of China

AUTHORS
1. Chih-Wei Yang¹, MD, ycwacad@gmail.com
2. Chih-Yu Yang², PhD
3. Pi-Fem Hsu², PhD
4. Li-Min Su², MS

Objectives: Public's stigma of HIV/AIDS is harmful to public health and human rights as well as other diseases. Several studies had been conducted to evaluate the public's attitude toward people with AIDS (PWAs) and how to improve it. However, in these studies, no standardized and validated evaluation scales has been used. Lack of appropriate control group such as severe mental illness was also noted. The objective of this study was to compare the public's stigma attitude toward PWAs and schizophrenia, which was one of the most stigmatizing diseases.

Methods: A total of 507 university students completed two questionnaires about the stigma attitude toward PWAs and schizophrenia. Each stigma questionnaire consisted of four subscales measuring familiarity, stereotype, dangerousness, and social distance. The four subscales were well constructed and validated in several previous studies, and were modified to better suit the purpose of this study. The subjects' basic data, religious belief, and health education experience were also collected.

Results: The scores of stigma attitude toward PWAs were higher in the stereotype and social distance but lower in the dangerousness subscale. Female subjects had higher scores in the dangerousness and social distance subscales with both questionnaires. Subjects with more health education experience had lower scores in several subscales of PWAs and schizophrenia questionnaires.

Conclusion: The results showed that the public's stigma attitude toward PWAs is more severe than schizophrenia in several aspects. Health education in university campus is a practical way to reduce the stigma attitude toward both AIDS and schizophrenia.

POST-TRAUMA RISK FACTORS AND RESOURCE TRANSFORMATIONS FROM THE PSYCHOSOCIAL PERSPECTIVE: A FOLLOW-UP STUDY

INSTITUTIONS
1. National Dong-Hwa University, Department of Clinical and Counseling Psychology, Taiwan Republic of China
2. Chung Yuan Christian University, Department of Psychology, Taiwan Republic of China

AUTHORS
1. Lin Yaw-Sheng¹, Mr., Ph, D, yslin@mail.ndhu.edu.tw
2. Hung Fu-Chien², Mr., Ph, D, hfc@cycu.edu.tw

'The study one' was adopted by the longitudinal approach to explore the Chi-Chi Earthquake victims' psychosocial resources changes from the three time intervals, namely, two years post the disaster, three and a half years post the disaster, and five years post the disaster. Two group of disaster victims (a group consisting of 149 adults with mean age 43.61±10.23 to be hit by the disaster, we called the general group, and a group consisting of 14 adults with mean age 42.00±9.47 who also lost their loved family ones during the disaster was called the bereaved group) were evaluated by the different scales at a disastrous site of central Taiwan. We found the trend that the bereaved group perceived the life threats and earthquake impacts were profound even five years had passed since the disasters. Also, the symptoms of the posttraumatic stress reactions were lessened for two groups along the time intervals. In 'the study two,' interviews with 20 bereaved and disorganized survivors at least once over a two-year period after the disaster were further analyzed. It was found from the psychological processes what the bereaved family coped against the major loss and established a form of continuing relationship that satisfied the emotional need of maintaining their ties with the deceased, including 'limiting the display of grief', 'refusal of plain explanation', 'attachment', and 'sublimation' and that the social structural processes of the traumatic experiences included 'impact of the disaster', 'support unconnected', and 'restructuring life'.

THE OUTCOME ANALYSIS OF PATIENTS WITH SCHIZOPHRENIA USING COMMUNITY PSYCHIATRIC REHABILITATIONS IN TAIWAN

INSTITUTIONS
1. Asia University, Institute of long-term care, Taichung, Taiwan Republic of China
2. National Taiwan University Hospital and College of Medicine, Department of psychiatry, Taipei, Taiwan Republic of China
3. Department of Health, National health insurance task force, Taipei, Taiwan Republic of China

AUTHORS
1. Ling-Ling Yeh, Professor, PhD
2. Hai-Gwo Hwu, Dr.
3. Shu-Cheng Liang

Objectives: The number of community psychiatric rehabilitation institutions (community rehabilitation center and half-way house) increased from 6 in 1995 to 136 in 2007, which might serve for more than one hundred thousands individuals. Apparently, the community psychiatric rehabilitation facilities are under-supply to individuals with chronic mentally illness. However, the limited numbers of the rehabilitation services are effectiveness or not still have to be surveyed.

Methods: The study conducts the national health insurance claim data analysis to figure out the effectiveness of community psychiatric rehabilitation. The National Health Insurance almost covers all beneficiaries and the Claim Data bank in this study recruits 105035 individuals with schizophrenia who ever diagnosed as ICD9 295 registered for medical services in the year 2000 and had a successive two-year follow-up treatment history.

Results: The study results show the utilization of community psychiatric rehabilitation centers and half-way houses only 0.3% and 0.8% in the first year and 0.6% and 1.0% in the second year follow-up, respectively. This cohort was classified into service and non-service group. The results reveal the service group has more utilization of psychiatry-related medical services than that of non-service group, while the service group has less utilization of non-psychiatry-related medical services than that of the non-service group.

Conclusion: The major benefit of the rehabilitation program is to reduce the utilization of non-psychiatry-related medical resources by the individuals with schizophrenia. The empirical data encourage more efforts to increased community psychiatric rehabilitation services for chronic mentally illness.

RELATIONSHIP BETWEEN THE SELF-CARE POWER AND THE LEVEL OF HOPELESSNESS OF THE ELDERS LIVING AT HOME

INSTITUTIONS
1. Ege University School of Nursing, Psychiatric Nursing, Bornova- Izmir, Turkey
2. Ege University School of Nursing, Public Health Nursing, Bornova- Izmir, Turkey

AUTHORS
1. Gönül Özgür, Dr., PhD, ozgurgonul@mynet.com
2. Serap Yıldırım, Mrs., camserap@yahoo.com
3. Aysun Babacan Gümüş, Dr., PhD, aysungumus@hotmail.com
4. Melek Özer Ardahan, Dr., PhD, melekardahan@hotmail.com

Objective: The study was designed to analyze the relationship between the self-care power and the level of hopelessness of the elders living at home.

Method: The descriptive-relational research was conducted with the participation of 101 elderly people from Turkey, İzmir Pınarbaşı Village Clinic in December 2005-May 2007. The data was collected by Introductory Information Form, Self-care Power Scale and BeckHopelessness Scale (1,2). Written approval was received from the institutions where the research was to be conducted and the participants gave oral approval.

Results: The average age of the elders living at home was 71.36 ± 5.75 and 53.5% were women while 46.5% were men. 32.7% were elementary school graduates and 46.5% were housewives. A negative relationship was determined between the self-care power and the level of hopelessness of the elders living at home ($r = -0.725$, $p<0.01$).

Conclusion: It was seen that as the level of hopelessness of the elders increases, the self-care power decreases. It was concluded that taking into consideration the significance of this relationship at home environments, the attempts to increase hope and therefore support self-care power would be vital in terms of increasing life quality of the elders was well as the quality of service they were provided.

FACTORS ASSOCIATED WITH LENGTH OF STAY AT AN ACUTE PSYCHIATRIC INPATIENT FACILITY: A CASE CONTROL STUDY

INSTITUTIONS
1. Melbourne Health, NWAMHS, Melbourne, Australia
2. Melbourne University, Psychosocial Research Centre, Melbourne, Australia

AUTHORS
1. Jianyi Zhang, Dr, FRANZCP, jianyi@bigpond.com.au
2. Carol A Harvey, Associate Professor, MD, c.harvey@unimelb.edu.au
3. Carol M Andrew, Ms, RPN, carol.andrew@mh.org.au

Aims: Factors associated with length of stay (LOS) were investigated, especially how LOS may be influenced by clinical practice and system issues.

Methods: A case control study was embedded in a retrospective cross-sectional clinical file audit of 226 randomly selected episodes of admission during a twelve-month period. A total of 286 variables were collected and analysed, which included socio-demographic, clinical and clinical practice/system variables.

Results: Logistic regression analyses showed that 10 variables were associated with LOS: 3 variables predicted prolonged stay and 7 variables predicted shorter LOS. Seclusion during the index admission, accommodation problems and living in an area lacking community services predicted longer stay. Variables that predicted shorter stay were being a migrant from non-western countries, having completed high school, having a drug and alcohol-related diagnosis, admission directly related to a crisis, adjustment disorder, cluster B personality disorder, and having recently transferred care. Several variables thought to be powerful predictors of LOS were found not to be so. They included living alone, living in marginal accommodation, LOS of previous admission, chronicity of illness, diagnosis of schizophrenia, severity of illness, risk on admission. Also the quality of inpatient or community care did not influence LOS.

Conclusions: LOS is multifactorially determined. Behavioural manifestations of illness resulting from a combination of factors and lack of social support structures predicted prolonged LOS. Good clinical practice did not necessarily translate to a shorter LOS. Therefore, LOS is predictable, but not readily modifiable within the clinical domain.

Objective: To evaluate impact of risperidone long-acting injection (RLAI) versus oral antipsychotics on hospitalization outcomes for patients participating in the electronic Schizophrenia Treatment Adherence Registry (e-STAR) in Spain.

Methods: e-STAR is a 2-year, prospective, observational study of patients with schizophrenia initiated on RLAI or oral antipsychotics. This report is based on the final, complete data from Spain. Hospitalization outcomes including number of hospitalizations and number of days in hospital. Changes in hospital stays and days in hospital were compared between RLAI and oral patients. This report is based on the final, complete data from Spain. Hospitalization outcomes including number of hospitalizations and number of days in hospital. Changes in hospital stays and days in hospital were compared between RLAI and oral patients.

Results: 1,622 patients (63.6% male, mean age 38.4 ±11.2 years) participated in e-STAR from Spain, 1,345 were initiated on RLAI and 277 were with oral. RLAI patients had significantly longer disease duration (12.6 ±9.5 years vs. 10.9 ±9.7 in oral patients, p<0.01). Average hospital stay at baseline was 5 days longer for RLAI patients than oral patients. During 2-year study, both treatments showed reductions in number of hospitalizations and number of days in hospital. Mixed-model regression showed, RLAI patients, compared to oral patients, had a significantly greater reduction in number of hospitalizations (-0.28 vs. -0.18 in followup-year1 and -0.37 vs. -0.20 in followup-year2, p<0.05) and number of days in hospital (-17.23 vs. -12.96 in followup-year1 and -18.75 vs. -12.99 in followup-year2, p<0.01).

Conclusions: This 2-year, prospective, observational study showed that compared to oral antipsychotics, RLAI treatment was associated with greater reduction in hospital stays and days in hospital in patients with schizophrenia.

DOMESTIC VIOLENCE AS PRECIPITATING FACTORS AT DEPRESSIVE DISORDERS INCIDENCE AMONG LOW-INCOME HOUSEWIVES IN RECIFE, BRAZIL

INSTITUTIONS
1. Catholic University of Pernambuco, Psychology and Masters in Science of Language, Recife, Brazil

AUTHORS
1. Moab Duarte Acioi1, Dr., PhD, mbaio@uol.com.br

From the existence of three distinct perspectives of approach of the health-disease: a scientific theory, the social construction and subjective experience, the aim of this communication is to analyze the discourses of low-income women outpatient at first consultation psychiatric concerning the illness narratives. The search occurred at the General Hospital Otavio de Freitas, of the Unified Health System in Recife, Pernambuco, Brazil. Among 68 women interviewed there was 34% of depressive disorders. In this group, the predominant age is 41-50 years (45%); religion is Catholic (55%); household income ranges from 1 to 3 minimum wages (55%) and the occupation are housewives (65%). In the results, was examined in speeches that the main psychosocial stressor was domestic violence, with the main agent her husband, and is characterized by alcoholization, negligence, betrayal and threats. Then there is a social violence, and victims mainly the children and then the husband and patient. This is related to mortality from external causes. In conclusion, it is necessary to look at an extension of the psychiatric clinic considering the dynamics of the family structure as the main stimulant of psychopathology and the same time, the main substrate for the therapeutic approach.

Introduction: Numerous studies in the past have been done to examine the association between severe mental illness and crime. It has been estimated that 20% of patients in high security psychiatric care have been diagnosed with substance misuse. Therefore this study looked at the association between substance abuse and criminal offences in those patients referred by courts to the forensic mental health services for psychiatric assessment in Malaysia.

Aim: To describe the lifetime prevalence of psychiatric and substance use disorders and to examine the rate of comorbidity in criminal offenders admitted for psychiatric assessment in the forensic mental health services.

Methods: This study was done by examining the psychiatric case records retrospectively. All admissions to this service for 3 year duration were examined. Personal data, details of committed offences, details of psychiatric history and details of substance abuse problems were recorded.

Results: There were 296 admissions to this service over the duration of the study; 83.6% of those were male patients. 54% has lifetime history of substance use with large proportion of them presented with the history of cannabis use. There was also strong association between substance use and psychiatric diagnosis among them. The presence of comorbid psychiatric illness and substance use has significantly associated with these patients (OR=2.17; p=0.05).

Conclusions: It is important to address the issue of substance use in the forensic mental health services. Substance use significantly contribute to the criminal offences among those who have been referred by the courts to the forensic mental health service in Malaysia.

**AUTHORS**  
1. Fatemeh Abasi¹, Mrs., MD, abasi.fatemeh@yahoo.com  
2. Fatemeh Alishahi¹, Mrs., MD  
3. Abdoljavad Ahmadi¹, Dr., PhD

This research investigate the effect of positive feeling to spouse on sexual function. The sample involved 82 married women aged between 18 to 45, from Qazvin, Iran. The subjects were selected randomly. The instruments of research were a demographics questionnaire and the sexual function questionnaire (SFQ) that dealt with female sexual function and positive feeling to spouse. The latter two questions are known to have high degree of validity and reliability. For data analysis, multivariate regression was applied. The research hypothesis was; “there is a relationship between positive feeling the spouse and sexual function.” The findings showed that positive feeling to spouse was a valid predictor for sexual function, in the three subscale of “desire”, “orgasm” and “enjoyment”. These findings highlight the fact that positive feeling to spouse influences sexual function in woman. It seems that there are meaningful relationship between sexual function and other dimensions of personality.

1. Asis Krishna Acharya¹, Dr., DPM, D.H., dr_asisacharya@yahoo.com

**INTRODUCTION:** Seasonal variation, effects of sunlight, and moon’s effects are thought from pre-historic ages as causative factor for Mental Disorders in different cultures. “Lunatics” stands for “psychoses” in assumption that lunar effect may have some etiological factors. In recent years we have established the fact that some affective disorders are characteristic of winter season only with lots of new symptoms like craving for starchy foods etc. Depression, especially bipolar-depression is very much pronounced in winter or cloudy rainy days when available sunlight is less light therapy has been advocated. Not only depression there are exaggeration of mania in spring or autumn and in summer. Keeping all these in view we retrospectically went through the records of patients attendance in a rural clinic of India.

**METHODS:** Case attendance records of “Mono-Susrusha” clinic, in Midnapore district,124km away from Calcutta was reviewed for the past 3 years 2005-07(Jan-Dec) in a month wise split up for the major psychoses, anxiety disorders and affective illness.100 such cases both male and females were analysed per-month figuring a total of 3000 patients.

**RESULTS:** Bipolar depression I was seen severe in winter (Temp12 degree cel.-17d.). Other depression shows in increase no. of consultation in winter as well in rainy season. Anxiety disorders, specially acute-panic-disorders consultations were much in very summer>40 degree Celsius, as well as in winter evening and nights. Manic 1st episode& relapse of acute mania are more common in spring, then summer and in autumn. A section however shows manic relapse in winter.

**CONCLUSIONS:** Season 1 patterns of incidence and prevalence of major mental disorders could be a new area of study in humid, hot and tropical countries like India.

Introduction: Psychological adjustment on breast cancer have impact on quality of life of affected women. Mechanisms of adjustment process are various, and becoming ill of cancer is highly traumatic stress event which have influence on development of psychiatric disorders.

Aim: To investigate whether liaison psychiatric approach have influence on anxiety and depression in patients with newly diagnosed breast cancer.

Subjects: Sample consisted of 120 women with breast cancer treated on Department for Oncology on Clinical Hospital Osijek. Including criteria were: female, age 18-65 years, newly diagnosed breast cancer, absence of other physical diseases, no history or presence of psychotic disorders, at least primary school, adequate verbal contact, signed informed consent for the patient.

Methods: Patients were in liaison psychiatric treatment for two months (psychopharmacology and psychotherapy procedures). Psychological assessment and psychiatric estimation was done thrice - on the first day, after one month and after two months of treatment. Detailed clinical examination with psychiatric interview using DSM-IV criteria for psychiatric disorders. Specially structured non-standardized questionnaire for estimation of potential ethiological factors for psychiatric disorders in patients. HAM-A for estimation of anxiety and HAM-D for estimation of depression. Data was analyzed by adequate statistical methods.

Results: Liaison psychiatric approach have significant influence on reduction of anxiety and depression in patients with newly diagnosed breast cancer.

Key words: breast cancer, liaison psychiatry, anxiety, depression

Safety therapeutic measures are one special type of criminal sanctions (penalty measures) applied on mentally ill criminal offenders. Their basic function is protecting society from dangerous behavior of mentally ill criminal offenders, with permanent or temporary mental illness, mental retardation or dependence on alcohol (alcoholism) or drugs (drug addiction). Acceptance of safety therapeutic measures as criminal sanction of special type is associated with the beginning of XX century. The first legal project including Safety measures as special type of sanction is Pre-draft of the Swiss Criminal Statute from 1893. Its author is K. Stos who had a significant impact on serious of legislations. The first legal project in our country to differentiate term of Safety measures from penalty is version of the Project of the Serbian Criminal Statute from 1911. During the 20’s and 30’s of the XX century numerous Criminal Statutes were supplemented by Safety measures as special type of criminal sanctions, both, in content and systematically differentiated from penalty as we know it today in almost all criminal legislations. Their implementation is imposed upon court procedure which proves execution of criminal act, but also uses psychiatric testimony related to determination of named mental disorders, mental incompetence or temporarily reduced sanity, to present a danger of repetition of socially dangerous behavior due to their physical condition. Current Criminal Statute distinguishes three types of Safety therapeutic measures:

a) Safety measures of mandatory psychiatric treatment and isolation in respective health facility
b) Safety measure of mandatory psychiatric put-patient treatment
c) Safety measures of psychiatric treatment of alcoholics and drug addicts

BREAST CANCER SCREENING BEHAVIORS IN A SAMPLE OF TURKISH WOMEN AND RELATIONSHIP BETWEEN SCREENING BEHAVIORS AND SELF-ESTEEM, BODY PERCEPTION AND HOPELESSNESS

INSTITUTIONS
1. Ege University School of Nursing, Department of Psychiatric Nursing, Bornova/Izmir, Turkey

AUTHORS
1. Olcay Cam1, Prof. Dr., PhD, olcaycam@yahoo.com
2. Aysun Babacan Gümüş1, Dr., PhD, aysungumus@hotmail.com

Objective: In addition to demographic, sociocultural and cognitive factors, psychological factors also have an effect on women's breast cancer screening behaviors (1,2). The purpose of this study was to examine breast cancer screening behaviors in Turkish women, the reasons for not doing screening behaviors and the relationship between screening behaviors and levels of self-esteem, body perception, and hopelessness.

Method: This research was conducted in an area covered by three neighborhood primary health care clinics in Bornova, Izmir. The data were collected between April and November 2006 from 382 women over 40 years of age who were selected using a stratified random sampling method. A Descriptive Information Form, Breast Cancer Health Belief Model Scale, Rosenberg Self-Esteem Scale, Body Cathexis Scale and Beck Hopelessness Scale were used for data collection in the study.

Results: According to the relationships that were established, as women's levels of self-esteem, body perception and hope increased, their self-confidence and health motivation increased, their perception of the benefits of BSE and mammography increased, and their perceptions of obstacles to doing BSE and mammography decreased.

Conclusion: Self-esteem, body perception and hopelessness were found to have an effect on women's breast cancer screening behaviors.

EVALUATION OF THE EFFECT OF EMOTIONAL SUPPORT-ORIENTED NURSING INTERVENTIONS ON PSYCHOSOCIAL ADJUSTMENT OF PATIENTS WITH BREAST CANCER

INSTITUTIONS
1. Ege University School of Nursing, Department of Psychiatric Nursing, Izmir, Turkey

AUTHORS
1. Aysun Babacan Gümüş1, Dr., PhD, aysungumus@hotmail.com
2. Olcay Cam1, Prof. Dr., PhD, Olcaycam@yahoo.com

Objective: This semi-experimental study has been conducted in pre-test post-test design with the purpose of examining the effect of emotional support-oriented nursing interventions on psychosocial adjustment of patients with breast cancer.

Method: The study was conducted in Ege University School of Medicine Department of Radiation Oncology Nurse Counselor Unit and Tulay Aktas Oncology Hospital Outpatient Chemothera- py Unit between September 01 2005 and June 31 2007. Sample of the research was consisted of 30 patients who met the criteria for sampling and completed emotional support interviews. Emotional support-oriented nursing interventions were improved by resear- chers in line with the related literature (1,2) and applied as totally 210-hour interview, in which 7 interviews were made with each patients individually. Introductory Information Form and Psycho- social Adjustment to the Illness Scale - Self-Report were used in data collection.

Result: It was determined that there was an increase in the patients' health care orientation, domestic environment, sexual relationships, extend family relationships and social environment, a decrease in their psychological distress levels and that there was no change in their adjustment to vocational environment following the emotional support-oriented nursing interventions.

Conclusion: According to these findings, it has been concluded that the applied emotional support-oriented nursing interventions are effective in enhancing psychosocial adjustment of the patients with breast cancer.

RELATIONSHIP BETWEEN CERVICAL CANCER EARLY DIAGNOSIS ATTITUDES AND SELF-ESTEEM, BODY PERCEPTION AND HOPELESSNESS IN TURKISH WOMEN

INSTITUTIONS
1. Ege University School of Nursing, Department of Psychiatric Nursing, Bornova/Izmir, Turkey

AUTHORS
1. Aysun Babacan Gümüş¹, Dr., PhD, aysungumus@hotmail.com
2. Olcay Cam¹, Prof. Dr., PhD, olcaycam@yahoo.com

Objectives: Psychological factors have an effect on women's cervical cancer early diagnosis attitudes (1,2). This study has been planned in order to examine the relationship between cervical cancer early diagnosis attitudes and self-esteem, body perception and hopelessness in women.

Methods: This study has been carried out between April 2006-January 2007 in an area covered by three neighborhood primary health care clinics in Bornova, Izmir. The data were collected from 390 women over 18 years of age who were selected using a stratified random sampling method. Data were collected by Introductory Information Form, The Scale of Attitudes Toward Early Diagnosis of Cervical Cancer, Rosenberg Self-Esteem Scale, Body Cathexis Scale and Beck Hopelessness Scale.

Results: It was determined that there was a low level relationship between perceived barrier and perceived benefit score means and self esteem and hopelessness score means which were related to women's cervical cancer early diagnosis in negative direction and there was a relationship between body perception score mean which was at low level, but in the positive direction.

Conclusions: It has been determined that as the women, who has taken part in the research, self esteem and body perception are getting higher, benefit perceptions related with cervical cancer early diagnosis have increased and barrier perceptions have decreased.

MENTAL HEALTH, SOCIODEMOGRAPHY AND CRIME IN CANADIAN PENAL INSTITUTIONS

INSTITUTIONS
1. Queen’s University, Centre for Neuroscience Studies, Kingston, ON, Canada
2. Queen’s University, Department of Psychiatry, Kingston, ON, Canada

AUTHORS
1. Victoria J Bae¹, Miss, MSc (cand.), 2vb4@queensu.ca
2. Julio E Arboleda-Florez², Dr., MD, DLF, D. PSYCH., arboledj@providencecare.ca

Mentally ill offenders represent a unique patient group that requires special care for their psychiatric conditions in addition to usual correctional supervision. This distinctive population is steadily growing across Canada, yet there is a severe lack of accommodations as evident in the overcrowding of the existing specialized facilities(1). It has been postulated that contributors and predisposing factors of mental disorders and crime, as well as characteristics of offenses committed by mentally ill, should be identified and studied as prevention measures. Identification of contributors and predisposing factors between mental illness and crime may help in the prevention of criminalization of the mentally ill.

The aims of this study are to identify how medical and psychiatric histories are related with current psychiatric state and criminological aspects in psychiatric offender population. Prevalence of mental illnesses will be determined along with medical, psychiatric and criminal history and general sociodemographic profiles in selected correctional facilities in Ontario. Some factors that interact with psychiatric prevalence rate and with criminology of affected individuals will be identified and the directionality of any such relationships may be elucidated. Institutions will be chosen to allow for diversity in the primary objectives and subsequent institutional environment, including Remand Centres (jails) that would allow a large capture for those individuals that are not sentenced to a prison term(2).

PSYCHOLOGICAL CONDITION DUE TO INFERTILITY ON WOMEN

INSTITUTIONS
1. Islamic Azad University, Zahedshar Unit, Fasa, Iran (Islamic Republic of)

AUTHORS
1. Jamaledin Alvani, Dr, MD, bahredar_m@yahoo.com
2. Mohammad Jafar Bahredar, Dr, MD, bahredar_m@yahoo.com

Background: Infertility is considered as a social and mental shock for many of the couples and is often very influential matter of life. The present research has been conducted to investigate the mental condition of the fertile women in comparison with the infertile women.

Method: The participants in this study consisted of 50 infertile women and 50 fertile women who were equalled with respect to the variables such as age, marriage period, profession, habitation situation and education and were compared by the General Health Questionnaire (GHQ-28) and SCL-90-R test.

Results: The results of this study reveal that there is a significant difference between the fertile and the infertile women in four area of the test: somatic complaints, anxiety, depression and disorder in social performance. Also the infertile women are less healthy than fertile women. It was observed a reverse correlation between the period of infertility and the mental health.

Conclusion: With regard to the injury of the infertile women to psychiatric problems, it is essential to have psychiatric centers to present psychological and psychiatric services.

4. Filomena Sousa
5. Silvia Ouakinin
6. Jorge Caldeira
7. Antonio Barbosa

Introduction: Personality has been almost not studied as a factor associated to metabolic control in Diabetes Mellitus (DM) type 2. However it is the basis of many psychosocial factors in adjustment and glicemic control.

Objective: To evaluate the relationship of personality with psychological adjustment, endocrine risk and metabolic control in DM type 2.

Method: 46 outpatients with DM2 from an General Hospital Diabetes Consultation were assessed in a cross-sectional design for diabetes psychological adjustment, cortisol/DHEA(S) ratio (endocrine risk), HbA1c (metabolic control) and sociodemographic variables. We used to detect personality items the NEO PI-R (Costa & McCrae, 1992 - Portuguese version) and for psychological adjustment a short 18 items Portuguese version of ATT39 (Dunn et al, 1986).

Results: Sociodemographic characteristics: Age (ys): 52.1 ± 9.3; Gender fem/male: 52.2 / 47.8%; Education (ys): 8.3 ± 4.3; BMI Kg/m2: 29.5 ± 5.1; Profession: 1:10.9% 2:21.7% 3:30.4% 4:23.9% 5:13% (lower levels correspond to wealthier professions) DM characteristics: DM duration (ys): 10.9 ± 7.9; ≥ 2 chronic complications: 52.2%; Insulin users: 23.9%; HbA1c: 7.66 ± 1.4%; Neuroticismo and extraversion correlated with psychological adjustment (r = -.310* and r = .411* respectively) and openness to experience to HbA1c (r = -.381*). Personality was not associated with endocrine risk. This factor correlates with HbA1c (r = .327*). With logistic regression (to HbA1 dicotomized by 7%) controlling for the significant previous variables obtained by bivariate statistics only psychological adjustment (OR: 0.86; CI95%: 0.75-0.99) and endocrin risk (OR: 1.15; CI95%: 1.00-1.32) were predictive.

Conclusion: Association between the most cultural and acquired dimension of personality with metabolic control fosters the effort on education of more resilient features in people with DM2.

PREVALENCE OF MENTAL DISORDERS AMONG JUVENILE OFFENDERS REFERRED TO CORRECTIONAL CENTERS IN SAO PAULO, BRAZIL

INSTITUTIONS
1. Institute of Psychiatry - University of Sao Paulo, Forensic Unit, Sao Paulo, Brazil

AUTHORS
1. andre C Valim¹, Dr., MD, andre.valim@gmail.com
2. Antonio P Serafim¹, Dr., PhD, apserafim@hcnet.usp.br
3. Daniel M Barros¹, Dr., MD, dan_barros@yahoo.com.br

Objective: To determine the prevalence of mental disorders in juvenile offender populations in correctional facilities in Sao Paulo, Brazil.

Methods: Mental health assistance was provided to juvenile offenders in custody in Sao Paulo, Brazil between January/December 2007. Twenty-two psychiatrists, through clinical interview and examination, evaluated 897 out of approximately 5000 committed youths (14-21yo), after referral by the correctional facilities’ staff.

Results: Of the 897 individuals assessed by clinical interview and examination, 628 (70%) received psychiatric diagnoses (ICD-10). Primary psychiatric disorders diagnosed were: substance abuse: 168 (26.7%); dissocial personality: 65 (10.3%); conduct: 54 (8.6%); depressive: 53 (8.4%); bipolar affective: 38 (6%); organic mental: 37 (5.9%); adjustment: 35 (5.6%); anxiety: 33 (5.2%); psychotic: 27 (4.3%), mental retardation: 26 (4.1%); unspecified personality disorders: 20 (3.2%); emotionally unstable personality: 20 (3.2%); dissociative: 15 (2.4%); others: 11 (1.8%).

Conclusions: Of 5000 offenders, nearly 20% were deemed worthy of specific medical attention. A high proportion of these presented mental health issues (70%). Diagnostic distribution is similar to that of other studies examining juvenile offenders, despite the fact that no specific diagnostic instruments besides a thorough clinical interview were used. Our study presents a selection bias since all examinees were previously considered worthy of medical assessment by non-medical staff. Results show that even without the use of instruments, prevalences obtained resemble previous findings, suggesting that psychiatrists may assess in a reasonably precise manner the actual mental health needs of youth correctional facilities.

EMOTIONAL INTELLIGENCE AND SATISFACTION WITH LIFE

INSTITUTIONS
1. Islamic Azad University, Azadshahr Branch, psychology, Azadshahr, Iran (Islamic Republic of)

AUTHORS
1. Ali Asghar Bayani¹, Dr, PhD, aliasghar.bayani@gmail.com

Objective: The psychometric literature in psychology and psychiatry has traditionally emphasized psychological dysfunction (Ryff, & Singer, 1998, Runi, Ottolini, Raffanell, Tossani, Riff, & Fave, 2003., Joseph, Linley, Harwood, Lewis, & McCollam, 2004). In the last few years, there has been growing interest in the positive aspects of psychological functioning, including psychological well-being, subjective well-being and emotional intelligence. The objective of this study was to investigate the relationship between emotional intelligence and satisfaction with life among university students.

Methods: The present study is a correlation research so, a sample of 311 students from Islamic Azad university of Azadshahr was randomly chosen. The participants answered a booklet which, in turn included three different instruments: A Demographic Questionnaire developed by the researcher himself, The Trait Meta-Mood Scale (TMMS., Salevery et al., 1995), and Satisfaction with Life Scale (SWLS., Diener, Emmonses, Larsen & Griffin, 1985). The data gathered were analyzed by SPSS using both descriptive and inferential statistics.

Results: There is statistically significant correlation between emotional intelligence and satisfaction with life (r = 0.25, á =0.01).

Conclusion: An increase in the level of emotional intelligence is associated with the improvement of satisfaction with life.

Aim: To determine whether there are differences in outcomes of the assessment process for male and female patients who are formally assessed for possible detention and compulsory admission under the Mental Health Act 1983.

Method: Data were collected over the period 2001-2005 inclusive on 4663 formal assessments. Rates of assessment were standardised for age and gender and analysed.

Results: Of these assessments, 2285 were on female and 2378 were on male individuals. There was a higher proportion of young men than young women aged 15-44 assessed (58% versus 42%); and this was reversed in older age groups with the 45-84 year old group ratio of people assessed being male 41% and female 59%. Following assessment, approximately 38% of both male and female patients were detained in hospital.

Conclusion: There may be a gender bias in the referrals to the assessment process, but there is no gender bias in the outcome of the assessments.

FEMALE ALCOHOLIC AND FAMILY DURING TRANSITION IN SERBIA

INSTITUTIONS
1. Institute for mental health, Belgrade, Serbia and Montenegro

AUTHORS
1. Danica Boakovic-Djukic¹
2. Vera Trbic¹

Gender’s influence on drinking patterns and alcohol related problems has attracted our attention on social influences on females drinking. In this paper, we tend to describe political, economical and sociocultural transitional crisis our country is going through, and it’s effects on women’s drinking. Drinking patterns of Female alcoholics were examined during three periods in our country: in period of decomposition of former Yugoslavia (1991-95), before, during and after NATO bombing (1999) and in period of democratic changing in socio-political context (2001-2005). The sample was consisted of Female alcoholics who are treated in our institution (Centre for Family therapy of Alcoholics) during this time. This comparative study confirmed that drinking patterns were changed depending of high stress situations (proximity to front line, refugee status, poverty, bombing etc). In Female alcoholics families, there is strong multiplicity of various problems. Engagement of identified patients and Family network was even stronger during those “bad” and stressful times. In conclusion, authors emphasize the preventive importance in work with those Families and wider systems, though more specific methods and techniques should be applied.

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Daniela Achette¹, Mrs., chpsicol@santacasasp.org.br

Introduction: The larynx cancer represents 25% of the malignant tumors that affect the head and neck region and 2% of all malignant diseases. There are various forms of treatment, the main one being surgical resection.

Aim: To evaluate the quality of life of patients with larynx cancer in late post-surgery, submitted to surgical treatment of supracricoid partial laryngectomy (SCL) or total laryngectomy (TL).

Method: Patients submitted to total laryngectomy with at least six months of post-surgery and considered good talkers by the Phonodigestion (Speech Therapy) service. We used the EORTC C-30 and the Hquestionnaires for the evaluation of the quality of life and the Anxiety and Depression Hospital Scale to evaluate anxiety and depression (HAD).

Results: 10 patients were evaluated, 5 submitted to total laryngectomy (TL) and 5 to supracricoid partial laryngectomy (SCL). The average age was 51 years in the group submitted to TL and 57 years in the SCL group. Schooling was similar in both groups. All the SCL patients considered their quality of life extremely good in both the generic and specific questionnaires and 20% of the TL patients considered their quality of life from fairly good to not so good in both cases. Regarding anxiety and depression, there was no significant data.

Conclusion: There is a tendency to a greater impact on the quality of life of patients submitted to TL when compared to those submitted to SCL.

Introduction: The ICU is a place to care for serious patients and there has been an increase in these patients’ life with the advance of technology. The re-implantation of the ICU’s Out-Patient Clinic sees to the need of an evaluation of the patients who have left the ICU allowing the team who assisted them to carry out a survey about present life, conditions of recovery, social and professional life. The outpatient clinic staff is multiprofessional, made up of: doctors, nurses, psychologists, social workers and physiotherapists.

Aims: To evaluate the quality of life and biopsychosocial adjustment of the patients who have left the ICU after hospital discharge. To obtain information about aspects of admission to ICU to be able to perfect the service and adapt treatment to the patient’s needs.

Method: Individual appointment with each member of the multiprofessional staff. Specific action protocols for each area involved were created. The patient is selected during admission period, according to criteria preestablished by the multiprofessional staff, so that he/she can attend scheduled appointments after hospital discharge. The patient’s needs and difficulties during stay at ICU and their consequences are identified. In case an outpatient clinic follow-up is needed, the patient will be sent to the specific areas.

Conclusion: The re-implantation of the ICU’s out-patient clinic will allow the multiprofessional team to evaluate the assistance of the patient who has left this Unit and obtain subsidies for an improvement in quality and humanization of assistance.

QUALITY OF LIFE OF PATIENTS AWAITING KIDNEY TRANSPLANT

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs, PhD, wlbruscato@uol.com.br
2. Paula Silva Kioroglo¹, Ms, chpsicol@santacasasp.org.br
3. Yvoty A. Sens³, Mrs., MD, chpsicol@santacasasp.org.br

Introduction: The quality of life of the patients with chronic renal failure suffers a considerable damage, interfering in their psychosocial routine, wearing them out emotionally and, consequently, interfering in their family and social relations as well as with the health staff.

Aim: To track data related to the quality of life obtained through the receptors' kidney pre-transplant psychological evaluation protocol.

Method: 100 receptors' psychological protocols were analyzed (1990–2007).

Results: Quality of life was considered satisfactory by 66% and unsatisfactory by 8%. Regarding the adjustment resources, 50% demonstrated to seek solutions when faced with predominant difficulties, 44% partially and in 6% a continuous damage was found when seeking adjustment solutions. The patient's family of origin was considered satisfactory in 64% of the patients and the current family nucleus was considered satisfactory in 68%. Regarding the patient's emotional state facing transplant, 64% was going through an adjustment reaction in the context of transplant, while, in relation to other circumstances of life, 60% presented a specific emotional problem: 58% related to the patient, 17% related to the family of origin, 13% related to the current family group and 12% related to the social environment. The emotional resources were, therefore, considered satisfactory in 50%, regular in 44% and unsatisfactory in 6%.

Conclusion: The presence of a chronic disease, the need for continuous treatment for a long period of time, as well as the presence of co-morbidities are factors that can interfere in this population's quality of life.

1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Mirella Baise Duque¹, Mrs., Ms, chpsicol@santacasasp.org.br
3. Valéria Wojciechowski¹, Mrs., MS, chpsicol@santacasasp.org.br

Introduction: The Rehabilitation Center is characterized by a multiprofessional treatment including Psychology Service, that seeks to improve the patients’ quality of life.

Aim: To help in the working out of the loss suffered, in the process of adjustment to the new physical, emotional and social conditions and neuropsychological evaluation.

Method: The consultations for children, teenagers, adults and elderly are held in the out-patient clinic as well as in the ward, individually or in group. The psychological group monitoring is held in the out-patient clinic with patients suffering from fibromialgy and who have suffered amputation, medullar lesion and cerebrovascular accident (stroke). The groups are characterized by a psychotherapeutical approach (done by the psychologist) and orientation and information (other specialists). The individual monitoring and the neuropsychological evaluation are done with the patients as well as families in the out-patient clinic and ward. The Psychology Service also works together with the staff, through case discussions.

Results and Conclusions: Patients deal in a more adequate manner with the losses suffered as well as identify strengths and weaknesses through the psychological monitoring and structure offered in this Center. The importance of this interdisciplinary treatment is emphasized in the process of physical rehabilitation.

GRiST: A WEB-BASED DECISION SUPPORT SYSTEM FOR MENTAL-HEALTH RISK ASSESSMENTS

INSTITUTIONS
1. Aston University, Computer Science, Birmingham, United Kingdom
2. University of Warwick, Warwick Medical School, Coventry, United Kingdom

AUTHORS
1. Christopher D Buckingham, Dr, PhD, c.d.buckingham@aston.ac.uk
2. Ann Adams, Dr, PhD, a.e.adams@warwick.ac.uk

Aims/Objectives: To describe the clinical implementation of GRiST (www.galassify.org/grist), a web-based tool for assessing risks associated with mental-health problems. GRiST uses a complex hierarchical structure of risk knowledge elicited from a panel of multidisciplinary mental health professionals [1]. This research describes how the knowledge helped develop and pilot a data-gathering tool.

Methods: The GRiST knowledge structure identified patient data used by assessors when making risk judgments and questions were devised for each piece of information. These were validated by individual clinicians and service users, a series of focus groups, and a working party of practitioners from the collaborating mental-health trust, culminating in a formal pilot of the GRiST data-gathering tool in the same trust.

Results: The GRiST data-gathering tool was organised into three main sections: rapid screening questions, clinical risk judgments, and additional information that need only be provided if required by the screening questions. Feedback questionnaires (51) for people using GRiST showed that respondents expressing either a positive or negative opinion about GRiST agreed it asked the right questions (78%), covered all important areas (80%), was clearly worded (85%), easy to understand (73%), and supported risk communication (79%).

Conclusions: Comprehensive risk data can be collected on a regular basis and used for web-based risk assessments if questions are quick to answer, logically grouped, and clearly identify information relevant to a particular assessment.

TYPICAL VARIANTS OF SELF-REGULATION DISORDERS AMONG EPILEPTIC OFFENDERS

INSTITUTIONS
1. The Serbsky National Research Centre for Social and Forensic Psychiatry, Department of psychogenias and personality disorders, Moscow, Russian Federation

AUTHORS
1. Marina Usukina, Mr, Professor, sveta-korn@mail.ru
2. Vera Bulygina, Mrs, PhD, ver210@yandex.ru

Aims and Methods: The study of 118 mail offenders with epilepsy diagnosis was devoted to clinical and patho-psychological factors of severe antisocial deeds. Some key characteristics of self-regulation were revealed by using standardized psychiatric interview and psychological tests. In our study we assumed the structure-dynamic approach; in which self-regulation was considered to be a cyclical conscious psychological process, which consisted of following phases: long-term planning, programming, modeling, and evaluation.

Results: The typical variants of self-regulation disorders were the following.
1. “Disconnectedness” within process, while the phases, themselves, were on high level of functioning. Specific for epilepsy personal treats increased the rate of negative attributions in a wide range of situations. Alcohol intoxication disrupted compensatory formed manners of self regulation and interpersonal relations.
2. “Disharmonious” profile of self-regulation with non-realistic planning and hyper function of programming. Epilepsy patients exhibited general cognitive morbidity and personal disorders. Negative symptoms in combination with suspiciousness and jealousy determined the evaluation even of neutral situations as hostile and threatened.
3. Low level of functioning of all phases of the process, with combination of sufficient evaluation abilities and lack of anticipating capacities. In the third variant: them criminal history and aggressiveness appeared much earlier than epilepsy manifestation. Such manner of self-regulation was more the result of preceding personal and conduct disorders, than the epilepsy outcome.

Conclusions: Structure-dynamic approach for understanding severe antisocial and aggressive behavior of mentally ill persons is assumed to be adequate in forensic psychiatry. This approach allows differentiating variants of self-regulation disorders.

CORRELATION BETWEEN SELF-ESTEEM, PERCEIVED COMPETENCY AND POSTTRAUMATIC GROWTH WITHIN WAR TORTURE SURVIVORS

INSTITUTIONS
1. Center for victims of torture, Sarajevo, Bosnia and Herzegovina

AUTHORS
1. Lejla Cakovic1, Dr, lelba@bih.net.ba

AIM: Aim of this research is to assess correlation between self-esteem, perceived competency and posttraumatic growth within war torture survivors

METHOD: Research sample consisted from 61 client of the Center for victims of torture from Canton Sarajevo who have experienced war torture. As research instruments Sociodemographic Questionnaire (CTV Sarajevo 2006), Rosenberg Self-Esteem Scale, Rosenberg Perceived Competency scale and Posttraumatic growth Inventory (Tedeschi and Calhoun) were used.

RESULTS: Positive and statistically significant correlation was detected between results on self-esteem scale, perceived competency and posttraumatic growth. Torture victims with high scores on self-esteem-scale had higher perceived competency and higher posttraumatic growth.

CONCLUSION: According to results of this research positive and statistically significant correlation was found between self-esteem, perceived competency and post-traumatic growth. Rehabilitation treatment of this group of clients is more successful and their full reintegration in society is expected.

PSYCHIATRIC NURSING EDUCATION IN TURKEY WITHIN EUROPEAN UNION PROCESS

INSTITUTIONS
1. Ege University School of Nursing, Psychiatric Nursing, Izmir Bornova, Turkey

AUTHORS
1. Olcay Cam1, Prof.Dr., PhD, olcaycam@gmail.com
2. Leyla Baysan Arabaci1, Mrs., MD, baysanarabaci@hotmail.com

Nursing education is held by the education programs including a variety of levels. Nursing education was commonly held by Health Vocational High Schools. They are still exist and the nurses graduated from these high schools have a common attendance in this field, but in recent years, nursing education is held more by the four-year graduate programs at university level. Nursing education at a level of university was started in 1955. The first master’s degree program began in 1968 and the first doctorate’s program in 1975 (2). Although there are 800 thousand nurses including 150 thousand graduated from university nurses, only 350 of them have master’s degree and are professional psychiatric nurses (1). One psychiatric nurse falls into 200,000 people. Most of psychiatric nurses work as academicians. In Turkey only 1% of psychiatry patients can benefit from the chance of treatment. There are 8 Mental Health Hospitals serving sanity. The high school-graduated nurses work in these hospitals. Because there are a few professional psychiatric nurses that their major function is in training the future generation nurses, having psychiatric nurses knowledge and perspectives. Psychiatric nurses carry out an important duty in the protection and development of mental health by utilizing the knowledge. Turkey is continuing to reform its healthcare system as it adapts to the European Union. Major changes in nursing education have occurred over the last decade.

In this study it was aimed to provide training for nurses and midwives about “postpartum depression” Total of 32 nurses and midwives were participated to the study. Before training program, a Survey Form developed by the researchers was applied to nurses and midwives. This Survey Form has 12 socio-demographic features and an Information Form that consisting of 12 information questions. Subsequently, nurses and midwives were given the training program in two sessions, each containing 10 individuals. The pre- and post training program mean scores of this form were compared. After that, the responses of this pre and post training mean scores and socio-demographic data were determined. Of the midwife-nurses participated in the research 72 % are working as midwives, 47 % are 36 years old or older. When the midwife-nurses’ pre and post training knowledge mean scores were evaluated, it was detected that the mean scores of diagnosing, treatment and preventing the postpartum depression and level of information were significantly higher in post training than pre training. According to these findings, it was concluded that in these trainings that they received would be helpful. It is recommended that nurses and midwives working in primary level should provide continuous and systematic trainings about this issue.

2. José Onildo Betioli Contel2, MD, PhD, jocontel@fmrp.usp.br

Aims/Objectives: The scope of this research is to study skills and knowledge required to biopsychosocial psychiatric practice in two countries. The aim is to try to understand how American and Brazilian psychiatrists are similar or not in their responses to standard questionnaire applied to psychiatrists in both countries. The results will be presented considering basically some types of psychotherapy.

Methods: The 1987’s American questionnaires of 48 skill items and 51 knowledge items required for psychiatric practice were translated, adapted and applied to Brazilian psychiatrists in 2000. The obtained results were compared, with emphasis on 12 items of skill and 10 items of knowledge of psychotherapies.

Results: Two invariance cores were identified, one of 27 skills and another of 45 knowledge. In psychotherapy prevail skills to conduct crisis intervention and knowledge to provide various types of psychotherapy, both in American and Brazilian results. But in the last 20 years psychiatrists of both countries put emphasis on a biological model of intervention, mainly on psychopharmacology. However, the need to provide crisis intervention and various types of psychotherapies shows that psychiatrists remain interested in psychological approaches to psychiatric practice.

Conclusion: This outcome means a great similarity between American and Brazilian psychiatrists at the proportion of 27/48 in skills and 45/51 in knowledge. The data showed a remedicalization of the psychiatric profession.

This paper assesses the major stages of the vital facts that took place in Juan N. Navarro’s life; among others: his studies, his teaching career and his role as the Secretary of the School of Medicine of Mexico City, his outstanding activity as headmaster of San Hipólito’s Hospital (oldest Mental Institution at the American Continent, f. 1566) and the School of Agriculture, as well as his political activities in the context of convulsive Mexican 19th century that even led him to take arms, finishing with the long period in which he was a General Consul in New York. It is necessary to particularly emphasize that he was the first one in our country who promoted the assistance for patients with mental illness, also applying the most advanced medical knowledge of the time for their treatment. In the conclusion of our analysis of Dr. Navarro’s personal story, we will stress that he was, together with his contemporaries, the prototype which defines the professional activity of an Latin-American physician who did not only practice medicine but also cultivated different forms of arts, basically the literature in all its expressions, and played in one way or another a preponderant role in the major public and social activities.

The students in the undergraduate health courses at a private university in São Paulo State, Brazil, receive pharmacology lessons in their curriculums, that address the pharmacokinetics and pharmacodynamics of drugs. Therefore, self-medication should not be undertaken by these academics even though the pharmaceutical industry incentivates the population extensively to purchase non-prescription medications and natural remedies. This exploratory, descriptive, survey type study with a quantitative analysis was carried out with the aim of identifying self-medication among undergraduates in health courses as a cultural practice or hypochondriasis. The sampling was a non-probability, accidental one composed of 196 students, enrolled in the pharmacy, biomedical, nursing and medical faculties. The instrument for data collection was composed of eleven open questions. The results showed that 176 academics self-medicated in spite of awareness about the dangers associated with this practice. The drugs used included cough syrups, decongestants, analgesics, antipyretics, antiespasmodics, antibiotics, anorectics (amphetamines acquired in manipulation pharmacies), anti-inflammatory drugs, antihistaminics, anti-depressants, also vitamins, antiacids and natural products for losing weight and inducing sleep. The source of the drugs included friends, parents or relatives, local “friendly” pharmacies, free samples and previous prescription leftovers. The investigation revealed that 161 academics confirmed that their parents selfmedicated and 66% agreed that it is an encouraged and established cultural practice, which despite some allergic reactions they intend to continue. Only 19 students revealed the criteria for hypochondriasis, perhaps exacerbated by their studies. Therefore, this investigation concludes that even with associated risks self-medication is easier than getting a doctors appointment.

CHILDHOOD ABUSE AND HEALTH DURING MENOPAUSE: WHAT IS THE RELATIONSHIP?

INSTITUTIONS
1. INSA- Investigaciones en Salud, Obstetrics and Gynecology, Duitama, Boyaca, Colombia
2. University of North Carolina, Psychiatry, Chapel Hill, United States

AUTHORS
1. Wilma I Castilla-Puentes, Dr., MD, wicastilla@hotmail.com
2. Sandra R Castilla-Puentes, Dr., MD, ksandrarocio66@yahoo.com
3. Carlos A Sanchez-Russi, Dr., PhD, insacolombia@yahoo.com
4. Ruby C Castilla-Puentes, Dr., MD, DrPH, ruby_castilla@med.unc.edu

Objective: To determine: (a) prevalence of childhood abuse history in Colombian middle-aged women, and (b) relationship between childhood abuse history and clinical manifestations during menopause.

Methods: Consecutive 408 (45-55 years) women during their annual gynecological visit in an out-patient clinic in Duitama, Boyaca, Colombia, filled in a self-administered standardized questionnaire, made up of two separate sections: (1) a medical section inquiring on menopausal symptoms, and (2) a section on abuse inquiring on the presence and type of abuse suffered during their childhood. Associations between number of symptoms and abuse history were evaluated using univariate and multivariate logistic models.

Results: The prevalence of reported childhood abuse was 19.1% (N=78). Among women reporting abuse, physical abuse was reported by 48 (11.9%), sexual abuse by 20 (2.7%) and both sexual and physical abuse were reported by a total of 10 women (2.2%). Women who report childhood abuse compared to those who do not have showed: More severe physical and psychological symptoms, more sleep problems, greater bodily pain, more genitourinary symptoms, are less physically active and poor function and low quality of life. Women who report childhood abuse are more anxious and pessimistic, have lower self esteem, have more chronic problems in relationships or in family members are more likely to have a history of recurrent depression. Furthermore, physical and sexual abuse were associated with a significantly (p<0.001) greater number of menopausal symptoms.

Conclusions: Women's childhood experiences with abuse influences their long-term health and may have implications for their assessments and treatment during menopause.

THE ROLE OF DEPRESSIVE, ANXIOUS AND SOMATIZATION SYMPTOMS IN QUALITY OF LIFE DECREASE IN REGARD WITH STRESS-RELATED DISORDERS

INSTITUTIONS
1. Institute of Mental Health, Department for Crisis Intervention and Affective Disorders, Belgrade, Serbia and Montenegro
2. Institute of Mental Health, Director, Belgrade, Serbia and Montenegro

AUTHORS
1. Olga U Colovic, Dr., MD, ocol@eunet.yu
2. Dusica Lecic-Tosevska, Dr., Prof. PhD

Some recent studies have shown a significant relation between posttraumatic stress disorder with decrease of the quality of life (1), while the research of relation of other disorders from a group of stress-related disorders with the quality of life is very scarce.

Objectives: To determine which symptoms (depressive, anxious, somatization) in stress-related disorders affect more the quality of life.

Method: We have compared the quality of life in 160 subjects who experienced stressful events. The first group (consisting of 80 subjects) was diagnosed with one of a stress-related disorders. The other group (consisting of 80 subjects) after a stressful life event did not develop any stress-related disorders.

Results: The subject diagnosed with one of a stress-related disorders had a lower quality of life. The presence of all three aforementioned groups of symptoms has negative correlation with the quality of life, they marked 40% of variation of the quality of life. Depressive symptoms (compared to anxious and somatization) in regard to stress-related disorders have the largest influence on the reduction of the quality of life.

Conclusion: Targeted psychotherapeutic and psychopharmacological intervention for depressive symptoms related to the stress-related disorders will have the most significant influence in improvement of their quality of life these individuals.

THE IMPACT OF TREATMENT ON QUALITY OF LIFE IN MAJOR DEPRESSIVE DISORDER (MDD) AND GENERALIZED ANXIETY DISORDER (GAD)

INSTITUTIONS
1. University Hospital Gasthuisberg, Belgium

AUTHORS
1. Koen Demyttenaere

Objective: To compare the quality of life using the Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) in patients with MDD or GAD, before and after treatment and to compare remission based on symptoms versus functioning.

Methods: Q-LES-Q and symptom-specific MADRS and HAMA data from 8 published randomised, 8-week, double-blind, placebo-controlled clinical trials with escitalopram were used. The short form of the patient-rated Q-LES-Q was used to assess patients' perceived quality of life and satisfaction at baseline and at last assessment. ANCOVA was used, adjusting for study, centre, baseline value, and treatment. MADRS and HAMA total scores were equated to Q-LES-Q using the method of equipercentile linking.

Results: MDD or GAD patients report a substantial degree of impairment in their quality of life (64% and 76% of community norm, respectively). Treatment with escitalopram resulted in statistically and clinically significant improvement in patient quality of life. The improvement was greater in remitters (MADRS<=12 or HAMA<=7) than in non-remitters and greater in patients treated with escitalopram than in patients treated with placebo. There was a strong correlation between each symptom scale (MADRS, HAMA) and the Q-LES-Q. The present analyses suggest that scores as low as 3-8 on the MADRS and 5-10 on the HAMA (complete remission) correspond to a Q-LES-Q score of 58 (+/- 10%), found in community comparison subjects.

Conclusions: Plotting symptom scales against QOL scales helps in defining cut-offs for remission for patients with MDD or GAD.

CRIMINAL RESPONSIBILITY IN PATIENTS WITH AXIS II PATHOLOGY

INSTITUTIONS
1. Psychiatric Hospital of Attika, Dafni, Athens, Greece
2. A Psychiatric Dept., Attikon Hosp., Medical School, University of Athens, Athens, Greece

AUTHORS
1. Christos K Tsopelas
2. Athanasios Douzenis
3. Anastasios Dimopoulos

Objectives: By definition everyone is considered to have knowledge of right or wrong and the free will to choose between the two. This is not always the case for a mentally ill offender, and the legal system in different cultures have a diverse approach for offences by the mentally ill, with “mens rea” or guilty mind as central concept.

Methods: Thorough research of the main medical databases and web search engines for relevant studies, agencies, organizations, and articles. We scrutinize them independently, before reaching consensus about appropriateness.

Results: Although exhibition of florid psychotic symptoms at the time of the offence are considered to impair the offender’s ability to act according to right or wrong, the penal system doesn’t accept the same for offenders with for personality disorders. This non-determinist approach is challenged by contemporary neurobiological research. Findings from brain imaging and genetic studies, raise the issue of determinism and the absence of free will, as AXIS and AXIS II pathology share neural pathways, genetic load, abnormalities in structure and function in brain regions.

Conclusion: The great advance in psychiatry and neurobiological research challenges the current leading non-determinist belief of the last centuries. The penal system is trying to follow these advances and contemporary arguments providing adequate and fair trial of the mentally ill offenders. The psychiatrists have a duty to disseminate any new knowledge, away from philosophical debates, having in mind both society's safety and their patients' needs.

DISCUSSING ASPECTS CONCERNING THE RIGHTS OF MENTALLY ILL PREGNANT AND HER EMBRYO

INSTITUTIONS
1. Psychiatric Hospital of Attika, Dafni, Athens, Greece

AUTHORS
1. Anastasia Angeli¹, Dr, MD
2. Christos K Tsopelas¹, Dr, MD, MSc, tsopelas@gmail.com
3. Anastasios Dimopoulos¹, Dr, MD

Objectives
Ms “K” a 32 years old woman, has been suffering from schizophrenia. During the last long admission she was found to be pregnant of 18 weeks. Treating psychiatrists consulted abortion, without giving adequate reasoning. Gynecologists had exceeded themselves and beside the caesarian section, also permanently sterilized her. Based on the above case, we performed research regarding the rights of the psychiatric pregnant patients and relevant legislation.

Methods: We have searched main databases (Medline, Psychinfo), and web search engines such as Google, local offices for patient’s rights, Universities’ databases for relevant studies and legislation, examine these independently, before reaching agreement.

Results: We found plethora of international codes, guidance, recommendations, acts regarding human rights and especially rights for the mentally ill. Besides these additional protective mechanisms for the mentally ill, there continue to exist differences in approach even among similar cultures. Convention of Human Rights appeared inadequate to protect effectively the rights of embryo in a new era of embryo research. Stem cell research and bioethics around it dominate the current debate, when right of mentally ill patients to bear life and the legal status of the embryo, are issues far more common.

Conclusions: Central to the debate between doctors’ paternalism and patients rights is the way that we interpret philosophical concepts of personal freedom, free will and decision making. Although clinicians are ambivalent in their views concerning pregnancy in mentally ill women, we argue that most patients can successfully rear children when given adequate support.

AUTHORS
1. Ewa J Wojtyna¹, Dr, MD
2. Małgorzata M Dosiak¹, Dr, MD, mdosiak@interia.pl
3. Patrycja Stawiarska², Ms

Aims/Objectives: Among women with breast cancer it very often comes to worsening of the physical functioning, losing the social roles, lowering the quality of life and higher risk of the mental disorders[1]. It favors in arising the cognitive distortions in perception of support, what in consistencies can influence in the further worsening social functioning[2]. Cognitive-behavior therapy (CBT) can help reduce those distortions[1]. The goal of the research was to explore the influence of CBT on perception of social support in women with breast cancer.

Methods: The studies had linear character, including two measurements - in the first and tenth week of chemotherapy. The study comprised 82 women after mastectomy and received chemotherapy, along with their partners. 42 women with their partners additionally participated in ten-weeks group cognitive-behavior therapy (CBT) in evaluating support one used Berlin Social Support Scales.

Results: In the initial measurement, one proved underestimate support evaluation in comparison with the evaluation of that support by women’s partners. In the second measurement the score of support and the equality of scores of both partners was higher in the CBT-group then in the control group.

Conclusion: Breast cancer favors cognitive distortions in the scope of perception of support. Psychotherapeutic impacts can bring about the elimination of the cognitive distortions and undertaking the actions aiming in improving the interpersonal relations.

FEAR DURING LABOR: THE IMPACT OF SEXUAL ABUSE IN ADULT LIFE

INSTITUTIONS
1. Norwegian Institute of Public Health, Division of Mental Health, Oslo, Norway
2. Akershus University Hospital, Department of Gynecology and Obstetrics, Oslo, Norway

AUTHORS
1. Malin Eberhard-Gran¹, Dr., MD, PhD, megr@fhi.no
2. Kari Slinning¹, Mrs, PhD, kari.slinning@fhi.no
3. Anne Eskild³, professor, MD, PhD, anne.eskild@medisin.uio.no

Objective: Our aim was to estimate the prevalence of women experiencing extreme fear during labor and to assess the impact of previous sexual abuse in adult life on extreme fear.

Material and methods: All postpartum women (n= 414) in two municipalities in Norway were invited to participate in a questionnaire study. Self reported fear during labor was coded “no fear / some fear / extreme fear”. Sexual abuse was measured by the Abuse Assessment Screen (AAS).

Results: Three percent of the women reported extreme fear during labor, 13 percent some fear and 84 percent no fear. Twelve percent reported sexual abuse as an adult. One third of the women with extreme fear during labor had been exposed to sexual abuse in adult life. Among women with a history of sexual abuse the estimated crude odds ratio was 1.9 (95% CI: 1.0-3.7) for reporting some fear during labor and 3.7 (95% CI: 1.1-12.9) for extreme fear. When controlling for depression, duration of labor and mode of delivery, the adjusted odds ratio for extreme fear increased to 4.9 (95% CI: 1.2-19.1).

Conclusion: The results suggest that women with a history of sexual abuse in adult life have an increased risk for extreme fear during labor.

5. Mohamed Denguezli², Pr., MD
6. Rafiàa Nouira³, Pr., MD
7. Béchir En Hadj Ali³, Pr., MD

Cutaneous Factitious Disorder (CFD) is a chronic psychodermatological condition leading to an impairment of quality of life. Its aetiology is still unknown, but the underlying mechanism seems to be dependent on life events.

Objective: This study aimed to compare life events and quality of life scores in patients diagnosed as CFD and in their siblings.

Methods: It’s a comparative study held in dermatology and psychiatry departments. Thirty female patients diagnosed as CFD according to DSM-IV criteria were prospectively recruited. Mean duration of the disease was more than 6 months in all cases. The siblings group consisted of their age matched sisters. Assessment was based on family and personal medical history, SF-36 quality of life scale and Paykel life events inventory.

Results: CFD patients and their sisters were respectively aged of 30±8.9 years and 30±6.1 years. They had the same social conditions and educational level but CFD patients were more often celibates (p<10^-4) and out of work (p<10^-4). Quality of life scores were lower in CFD group (1285±544 vs. 2546±401; p<10^-4). Also, global scores (p<10^-4) and negative impact (p<10^-4), as measured by Paykel life events inventory, were higher in CFD patients.

Conclusion: More life events and more severe negative impact were found in CFD patients. A role of these events may then be proposed as an environmental mechanism of CFD. Besides, quality of life was impaired in CFD patients comparing to their sisters. These results outline the importance of considering such measures in organizing multidisciplinary care proposed to those patients.

A STUDY ABOUT SECONDARY ALEXITHYMIA IN ONCOLOGICAL PATIENTS

INSTITUTIONS
1. Department of Clinical Psychology and Psychotherapy “San Martino” Hospital, Genoa, Italy
2. Psychiatric Care Unit “Ospedale Galliera”, Department of Mental Health, Genoa, Italy

AUTHORS
1. Francesca Riccardi1, Dr
2. Giovanna Ferrandes1, Dr, giovanna.ferrandes@hsanmartino.it
3. Luigi Ferrannini2, Dr, luigi.ferrannini@galliera.it

Objective: This study proposes to observe alexithymia in patients undergoing a long hospitalization and to value the hypothesis of connection between secondary alexithymia and the disease as a crisis event that implies several weeks of isolation, able to destructure the emotional adjustment’s system.

Methods: During a period of six months, between December 2006 and May 2007, 22 patients undergoing Allogenic Bone Marrow Transplant (ABMT) were assessed by: a) semi-structured interview, b) TAS-20; c) POMS.

Results: At T1, the sample shows alexithymia in 53% of cases, but at T2 just two patients seems to maintain the trait. It doesn’t come out a connection with educational qualification, but alexithymia seems to be related to hospitalization’s length and POMS’ outcomes, as a global evaluation of Mood Disorder.

Conclusions: The mental representation of a disease of the hematopoietic system has got distinctive features, especially about the defense mechanisms and the symbolic meaning related to the blood. The ABMT triggers regressive defenses, denial with a deep influence on dependence/independence dynamics. It’s suggested, from a clinical point of view, to implement psychological assessment and supportive sessions and, with respect to the research, to extend the studies about the mental representation and the evaluation of psychopathological risk factors.

SELF REPRESENTATION INTO ALLOGENIC BONE MARROW TRANSPLANTED PATIENTS

INSTITUTIONS
1. Department of Clinical Psychology and Psychotherapy, “San Martino” Hospital, Genoa, Italy
2. Psychiatric Care Unit, “Galliera” Hospital, Department of Mental Health, Genoa, Italy

AUTHORS
1. Maria Teresa De Benedetti1, Dr
2. Giovanna Ferrandes1, Dr, giovanna.ferrandes@hsanmartino.it
3. Luigi Ferrannini2, Dr, luigi.ferrannini@galliera.it

Objective: This paper aims to describe preliminary results of an undergoing research, which is directed towards the understanding of the self representation and to outline a possible profile of psychological functioning of patients subjected to allogenic bone marrow transplant (ABMT).

Methods: Our work uses both clinical and research activity. The study foresees clinical interview, Rorschach and BDI-II Beck Depression Inventory test, given to 10 patients subjected to BMT from October 2007 to May 2008. Rorschach test was chosen not only as diagnostic tool, but also as support for patient’s fantastic and relationship activity. <strong/>

Results: The study is currently undergoing. Preliminary results do confirm the importance of self representation modification and the complexity of psychic structure rebuilding of a patient forced for long time into isolation.

Conclusions: The study is not only research oriented, but aims also to help patients to integrate the disease into one’s history, to turn emotions into words and permit images and thoughts to became representable, otherwise they would be too painful and cause of vulnerability. Psychic study of BMT patients allows to improve clinical knowledge of emotional reactions and the process of psychic adaptation in isolation in order to better react to the patient’s emotional needs and to encourage a good quality of life during post surgery phase.

SERUM PROLACTIN LEVELS IN PERIMENOPAUSAL WOMEN WITH RECURRENT DEPRESSION

INSTITUTIONS
1. Instituto Nacional de Psiquiatría, Clinical department, México city, Mexico
2. UNAM National University of México, Research department, Mexico city, Mexico

AUTHORS
1. Monica Flores¹, Dr, MD, flores_ramos@hotmail.com
2. Gerhard Heinze¹, Dr, MD
3. Ignacio Mendez², Dr, PhD

Several abnormalities has been documented in depression, including dysregulation in prolactine secretion (1). Prolactine level has been proposed as a predictor of response to antidepressant treatment (2). The aim of the present study was to evaluate prolactin plasma levels in a group of perimenopausal women with first episode of depression, recurrent depression, or without depression.

Method: A total of 20 outpatients were reclused in in México City, between March 2006 to September 2007. They were women 45 to 55 years old, cursing perimenopause according to OMS criteria. Patients were divided in three groups: 1) first depression episode (n= 5), 2) recurrent depression (n=7), or without depression (n=8). Patients taking hormone drugs or psychotropic drugs were excluded. Evaluations were carried out using the Mini International Neuropsychiatric Interview and the Hamilton Depression Rating Scale (17 items). Prolactin serum levels were measured every two weeks in three occasions. We observed significantly higher levels of prolactin in women with recurrent depression compared with women with first depressive episode or controls.

Conclusion: Further studies to evaluate prolactin levels in a more representative sample of perimenopausal women are suggested to examine the relationship between this hormone and depression associated with perimenopause.

EFFECTIVENESS OF TEAM BASED LEARNING: COMPARING EXPERT AND NOVICE LEADERS

INSTITUTIONS
1. University of Michigan Medical School, United States

AUTHORS
1. Tamara L. Gay¹, Dr., MD
2. Divy Ravindranath¹, Dr., MD, MS
3. Brian Martis¹, Dr., MD, MBBS

Background: Team-Based Learning (TBL) allows a single instructor to facilitate several small groups of learners in a single classroom. [1] We decided to transition to TBL experiences for 3rd year clerkship core content presentations. Nine content areas were presented as lectures until academic year 2006-2007. During that year Dr. Ravindranath gave each Mood Disorders presentation as a TBL experience. We now consider him an “expert” in TBL techniques. This year Dr. Ravindranath has continued with TBL Mood Disorders presentations. We have expanded and have seven faculty members utilizing TBL for the Anxiety Disorders presentations.

Method: Approximately one hour of training in TBL techniques was given to the seven “novice” presenters by the “expert” presenter. This included providing the novices with all necessary case and Readiness Assessment Test (RAT) materials. The student evaluations from this current year’s Mood Disorders TBL presentations (given by an “expert”) will be compared with Anxiety Disorders TBL presentations (given by “novices”). We will utilize paired t-tests for the comparisons. The data will include approximately 165 student evaluations.

Results and Conclusions: Analysis from the first two rotations demonstrates no significant difference between “expert” and “novice” leaders. We will present a complete data set at the 2008 meeting. We believe growth of TBL applications and utilization will be to facilitate recruitment of new TBL presenters. By demonstrating that “novices” are as effective as “experts” we hope that TBL expansion will be accelerated.

4. Anita Benko⁵
5. Dorottya Pap⁶
6. Andras Vargha⁷
7. Gyorgy Bagdy⁷

Objectives: The cyclical fluctuation of reproductive hormones throughout the female reproductive cycle is often accompanied by mood fluctuation, which in certain cases is severe enough to meet diagnostic criteria. However, the role of personality in premenstrual symptomatology has not been described in details. Our aim was to investigate the association of temperament and character dimensions in psychiatrically healthy, non-PMS women with severity of symptoms experienced in the late luteal phase of the menstrual cycle.

Methods: 40 healthy women completed the Prospective Record of the Severity of Menstruation (PRISM) calendar every evening through three consecutive menstrual cycles. Based on an at least 30% increase in PRISM scores from the follicular to the late luteal phase, participants were assigned into PMS vs. nonPMS groups. Personality characteristics were evaluated using the Temperament and Character Inventory (TCI). Mean TCI scores in the two PRISM groups were compared.

Results: Novelty seeking (NS), self-directedness (S), cooperation (C) and self-transcendence (ST) scores were significantly higher, while harm avoidance (HA) scores were significantly lower in PMS subjects.

Conclusions: Our results are in contrast with previous studies concerning personality traits associated with premenstrual syndrome. However, we investigated healthy women, and therefore our results indicate that these characteristics of women who experience more severe symptoms in the late luteal phase of the cycle can be considered protective factors which work against the development of PMS when experiencing more distress resulting from the emergence of symptoms associated with the fluctuation of reproductive hormones.

These studies were supported by LSHM-CT-2004-503474.

Purpose: This research is designed to identify the effect of the magnetic field created by the computer on depression.

Methods: The descriptive research was carried out with 121 participants, who spend at least one hour on computer per day, at Ege University Faculty of Medicine between 27 February and 28 April 2006. The data was collected by introductory information form and "Beck Depression Scale".

Findings: It has been found out that 66.10% of the participants spend more than five hours on computer, 41.30% do not have a break unless at least two hours pass and 60% do not take any precaution against the harmful effects of the computer. On the one hand, it was found out that average depression score of the participants was 11.51±7.51 and average depression score was affected by the time spent on computer and having a break during this period (p<0.05).

Conclusion: Average depression score of the participants was found to be as "having no depression" and it has been concluded that there was a close relation between average depression score and, the time spent on computer and having a break during this period.

Background: Participatory arts projects for people with mental health needs typically claim outcomes such as improvements in confidence, self esteem, social participation and mental health. However, such claims have rarely been subjected to robust outcomes research. This article reports a national outcome evaluation of art projects participants.

Methods: Study sample were 62 mainly female new entrants with mental health needs attending 22 arts projects across England. Outcomes were quantified through questionnaires on first entry and at 6 months. Measures assessed: Empowerment, mental health (CORE) and social inclusion. T-tests compared overall change and subgroups were analyzed with repeated measures ANOVA, including age, gender, educational level, mental health, and participation.

Results: There were significant improvements in empowerment (p<0.01); mental health (CORE) p<0.03) and social inclusion (p<0.008). Participants with higher CORE scores, no new stress in their lives and positive impressions of impact of arts on their life benefited most over all three measures. Positive impressions of the impact of arts and empowerment were significantly associated (p<0.001), but not mental health or social inclusion.

Conclusions: This study suggests arts participation positively benefits people with mental health difficulties. Arts participation increased empowerment and had potential to impact on mental health and social inclusion.

Objectives: To inform the design of relevant continuing medical education in HIV psychiatry, we conducted a mixed methods needs assessment examining the perceived learning needs of psychiatrists working in Sub-Saharan Africa.

Methods: In part one, we used focus group discussions to investigate perceived learning needs, preferred learning methods and involvement in, and barriers to, participation in educational programming in HIV psychiatry.

Results: Twenty nine psychiatrists (13 female), working in seven Sub-Saharan countries, participated in five focus groups conducted in 2007. Over and above limitations in human and financial resources, participants identified the stigmatization of psychiatry within medicine and the lack of integration of medical and psychiatric services, as being key barriers to feeling connected in the provision of care for HIV+ patients. Many participants identified that care systems have not identified active roles for psychiatrists in comprehensive HIV care, which has often led to non involvement in HIV training opportunities. In addition to identifying learning needs in content areas of HIV psychiatry, participants also identified a need for discussion opportunities of complex issues that arise in the care of HIV+ patients, including ethical, legal and advocacy issues. Participants identified a preference for case-based educational programming that promoted discussion and would strengthen collaborative relationships between African settings. Web based/internet learning was viewed as not practical by most participants due to resource constraints.

Conclusions: Educational programming in HIV psychiatry should include system level interventions that will facilitate the involvement of psychiatrists and promote discussion opportunities in complex medical-psychiatric interface issues.

HOMOPHOBIA AMONG MEDICAL STUDENTS: A TEN-YEAR SYSTEMATIC REVIEW

INSTITUTIONS
1. Instituto de Investigación del Comportamiento Humano, Dirección, Bogotá, Colombia

AUTHORS
1. Edwin Herazo1, Dr., MSc, eh@comportamientohumano.org
2. Adalberto Campo-Arias1, Dr., MD, campoarias@comportamientohumano.org

Objective: To know the prevalence of homophobia and the associated variables among medical students during the last decade.

Method: A systematic review was carried out of original articles published in Ebsco, Imbiomed, Lilacs, MedLine, Ovid, and ProQuest. It was included articles published between 1998 and 2007 in English, Portuguese and Spanish. The key words used to search were “homophobia”, “homosexuality” and “medical students”. Descriptive analysis of information was done.

Results: A total of five articles were included. Only two articles reported homophobia prevalence. The prevalence of homophobia was between 10% and 25%. Homophobia was related to religious beliefs, male sex, less age, lower sex knowledge, never having experienced sexual intercourse, right-wing political orientation and lower family income (1, 2). In addition, HIV/AIDS-phobia was associated with homophobia.

Conclusions: Homophobia is present at least 10% of medical students. Religious beliefs and male sex are the most important associated factors. This finding has an important implication for public health to prevent HIV infection. More investigations are needed.

Acknowledgements: This research was supported by Instituto de Investigación del Comportamiento Humano (Human Behavioral Research Institute), Bogotá, Colombia.

WEIGHT MANAGEMENT ACTIVITIES IN OUTPATIENTS WITH ANTIPSYCHOTIC TREATMENT

INSTITUTIONS
1. Chiayi Christian Hospital, Department of Psychiatry, Chiayi city, Taiwan Republic of China

AUTHORS
1. Chou Yu Hsuan1, Dr., MD, f501@cych.org.tw
2. Yuh-Ming Hou1, Dr., MD, c151@cych.org.tw

Objectives: We conducted a weight management program for overweight psychiatric outpatients who were taking antipsychotic medicine and to study its effectiveness.

Methods: Adult psychiatric outpatients (N=23), who were taking antipsychotic medicine for at least one year with BMI > or =22 and motivation to have weight management, received 10 weekly sessions of weight management activities at Chiayi Christian Hospital. Patients with eating disorders, mental retardation and psychosis related to drug or alcohol were excluded. Pre- and post-program weight, BMI, body fat, blood sugar, cholesterol, triglyceride, waist, hip, ADL degree, concentration and hands functions were measured. Feedback evaluations were done before and after the program. The “Paired Sample T Test” was utilized to distinguish the differences between the pre- and post-program.

Results: The findings indicate (1) there were significant improvements of body weight (mean weight loss 5.3kg) and on other variables such as weight, BMI, body fat, cholesterol, and waist, hip circumference. (2) Weight management activities offered great opportunities for psychiatric outpatients' lifestyle improvement. (3) Participants’ feedback evaluations indicated the program as one of good group support resources.

Conclusions: The results sustain that weight management approach was affirmative to healthy lifestyle for outpatients during the antipsychotic treatment. Further studies with larger sample size and long term monitoring are needed.

Objective: This is a cross-sectional and controlled study for the sake of examining the correlation between psychopathology, menstrual irregularity, and menstrual distress symptoms with attitudes toward menstruation in women with schizophrenia and schizoaffective disorders in Taiwan.

Design: Psychopathology was assessed by psychiatrists using the Positive and Negative Syndrome Scale (PANSS). Patients treated with anti-psychotic medications for at least the previous six months were placed in irregular (irregular menstrual cycle) (n=31) and regular (regular menstrual cycle) (n=27) groups. Sixty-two, age-matched, and healthy female participants with regular menstruation cycles were included as a controlled group. The Menstrual Attitude Questionnaire (MAQ) was used to assess attitudes toward menstruation, and the symptoms based on the Moos Menstrual Distress Questionnaire (MMDQ) were used to assess menstrual distress symptoms.

Results: The results showed that compared to the control group, the patient groups (regular and irregular groups) had more negative attitudes toward menstruation. There was no association between the severity of psychotic symptoms and its impacts on attitudes toward menstruation.

Conclusions: In terms of patients with schizophrenia or schizoaffective disorders, this current study has found their attitudes toward menstruation more predictable by means of the regular menstrual cycle and the severity of somatic menstrual distress symptoms.

Key Words: Menstrual attitude questionnaire, schizophrenia, menstrual irregularity, menstrual distress questionnaire, menstruation

The quality of life of the person with mental illness must be a central focus of care. What remains of “the good life” when one suffers of mental illness like schizophrenia?(1)

Objectives: This study examined quality of life of 964 out-patients with mental disease, aged between 20 to 50 years old. All the patients come from Psychiatric Hospital Socola Iasi, Romania.

Methods: The patients answered to a questionnaire comprising 35 questions related to quality of life. The questions addressed self-appreciation behavior, cognition, opinions, and the attitude toward social life of the respondents. These were aimed at highlighting: 1. Frequency of symptoms; 2. Quality of life and the patient’s opinion about this; 3. Interference between the disease and both social and professional life.

Results: We present a descriptive analysis of both the aspects of quality of life in the out-patients and the particularities our country.

Conclusion: Determining how another person would define quality of life is not easy, but it is extremely important. However, as a problem of principle besides what is understood by quality of life it appears the question regarding to the conditions that should be created so that this quality should be warranted and optimized.(2) This last aspect is totally dependent on the society through the social and legislative system created by it.

OBJECTIVES: This study was conducted to examine the factors relating to anxiety, depression and abusive behaviours in mothers with children aged less than 1 year.

METHOD: Data was collected from baby check-ups in Japan, and 423 mothers participated. The questionnaire included (1) State-Trait Anxiety Inventory (STAI), (2) Self-rating Depression Scale (SDS), (3) Parental Bonding Instrument (PBI) and (4) Childcare Anxiety Scale (CAS, Teshima, 2003). Covariance structure analyses were performed to examine (a) how the three subscales of CAS: ‘worry about parenting’, ‘difficulty of bonding’ and ‘burden of nursing time’, have influences on state-anxiety, depression and abusive behaviour, (b) how the PBI subscales affect the CAS subscales.

RESULTS: Of those mothers, 9.1% showed high levels of anxiety (STAI state-anxiety ≥55) and 14.7% showed more than moderate levels of depression (SDS ≥50). All of the CAS subscales affected anxiety and depression, but ‘difficulty of bonding’ affected state-anxiety more than it did depression, and ‘difficulty of bonding’ an state-anxiety affected abusive behaviour. In the other analysis, ‘mother-care’ had the most negative influence on ‘difficulty of bonding’ among the three subscales, and ‘mother-over-protection’ only affected ‘difficulty of bonding’.

CONCLUSION: The findings of this study suggest two models of the mental problems that some mothers experience. One model, the ‘Nervous Model’, proposes that anxiety and depression arise from excessive worry and senses of responsibility on parenting. The other model, the ‘Poor Bonding Model’, proposes that anxiety and abusive behaviour are linked to difficulty of bonding with their children under the influence of these mothers’ relationships with their own mothers.

We have lead Dasein-analyse (Binswanger L.) at oncological patients. The following attributes have been revealed in all cases: absence of self-realization and self-actualization, dissatisfaction with a life, refusal of own interests. The sharp stresses which changed a life came to light and did its less safe in some cases. «The syndrome of expectations» when the patient as though expected events during all life, instead of veins a full life was very important. 3-5 years prior to cancer disease were found out the depression attributes. Presence of depression reduces «psychosomatically immunity». Conscious and unconscious conflicts act on immune system negatively on the mechanism of mental immunomodulation. As a result, immunity decreases, and it promotes cancer development. Pathogenetic mechanisms of depression and tumor growth are integrated.

More digital information is available and because of Information overload it is a natural reaction to refrain from visiting libraries and updating professional retrieval skills. This presentation will invites cross-disciplinary exchange of ideas and initiatives and web-initiatives. Librarians become more and more also providers of the technological side, the information and skills necessary to implement the most effective social software technologies: blogs, RSS, wikis, social networking software, screencasting, photo-sharing, instant messaging, gaming, and more. Libraries play a role in repair and reparation in disasters and in countries of war as a symbol of society. In these cases libraries can function be as hospitals and knowledge like medicine. 1. knowing when individuals have a need for information 2. identifying information needed to address a given problem or issue 3. finding needed information and evaluating the information 4. organizing the information 5. using the information effectively to address the problem or issue at hand 6. define other groups low IQ and information illiterate that can profit from WSIS and IFLA initiatives. Attending conferences of WSIS, IFLA, visiting libraries, visiting websites from library associations have been for me an important source of inspiration. I would like to share some experiences that could be of interest for both psychiatrist as for patients.

Libraries for psychiatry fits in the congress team "Science and humanism and a person centred psychiatry". This articulation of science and humanism to optimize attention to the ill and positive health aspects of the person is also reflected in themes of WSIS summit and UNESCO and IFLA. This presentation is a follow up the ideas that were put forward in the XIII world conference of psychiatry in Egypt. Two themes -technologies in context of society and -libraries are reflected in The World Summit of the Information Society (technology) themes and the WSIS- IFLA implementation program (International Federation of Library associations libraries) are symbolically put together in the UNESCO website. Studying these themes gives insight who will be excluded and included, digital divide, open access and issues of literacy. In a Program on Psychiatry for the Person both for professional as patients one should ask the question how are libraries and digital libraries made clinically fit and especially interdisciplinair. Libraries play a role in repair and reparation in disasters and in countries of war function as a symbol of civil society. Attending conferences of WSIS, IFLA, visiting libraries, visiting websites from library associations have been for me an important source of inspiration. I would like to share some experiences that could be of interest for both psychiatrist as for patients.

Objective: Previous studies have reported that depressive symptoms in the patients with breast cancer may have a harmful effect on the prognosis of breast cancer. To investigate the current psychological characteristics and their long-term effect on prognosis of patients who were very recently diagnosed as breast cancer.

Methods: Thirty-eight subjects with breast cancer were evaluated before scheduled surgical operation. The psychological symptoms of the patients were assessed using Beck Depression Inventory (BDI), Montgomery-Asberg Depression Rating Scale (MADRS), State-Trait Anxiety Inventory (STAI) and Self-awareness Scale. Their mental coping was assessed using Korean Mental Adjustment to Cancer scale (KMAC) and their health-related quality of life was assessed with Short Form 36-item Health Survey (SF-36). The cut-off points of BDI and MADRS for the depressed group were 13 and 10, respectively. Psychological characteristics of depressed patients were compared with non-depressed patients.

Results: Sociocultural variables including age, education and cancer stage were not different between groups. The depressed group (n=19) showed significantly higher state-anxiety and lower trait-anxiety and positive self-awareness compared to non-depressed group (n=19). The depressed group showed significantly lower score of mental health component and fighting-spirit factor in SF-36 and higher score of anxious-preoccupation factor in K-MAC.

Conclusion: When the patients were diagnosed with breast cancer, depressed patients may have poor quality of mental health and more psychological suffering. These suffering may lead to maladaptive compliance to following treatment. Therefore, depressive symptoms need to be evaluated at the initial step of breast cancer treatment.

This study investigated reliability and validity of the DSM-IV Axis V scales, the Global Assessment of Functioning Scale (GAF), the Global Assessment of Relational Functioning Scale (GARF) and the Social and Occupational Functioning Assessment Scale (SOFAS) in ninety-five veterans with chronic combat-related PTSD. The subjects were diagnosed according to the Structured Clinical Interview for DSM-IV Axis-I Disorders (SCID-I) and rated by trained clinicians on the three DSM-IV axis V scales, the Brief Psychiatric Rating Scale and the Count of PTSD Symptoms on the SCID-1 (PTSD-COUNT). The GAF (Mean=65), SOFAS (Mean=61) and GARF (Mean=54) showed acceptable levels of interrater reliability in terms of Intraclass Correlation (0.78 to 0.83). Correlation analyses revealed that the GARF and the SOFAS were each more related to the GAF (r=0.82 and r=0.56 respectively) than they were to each other. A factor analysis was performed on the scores for the the Axis V scales and revealed that these scales measured similar construct, i.e. unif factor which accounted for 75% of the variance observed in the variables. According to multiple regression (R=0.81, R²=0.66) the factor score conceptually representing disability was significantly correlated with measures of both global psychopathology (the BPRS) and traumatic stress (the PTSD-COUNT). Our findings confirmed both reliability and validity of the DSM-IV Axis V scales in measuring disability due to PTSD, which has important implications both in sense of treatment to minimize disability and in the domain of personal injury litigation.

2. Bi-Hwa Wang, Mrs., Master
3. Chia-Yi Liu, Dr., MD

Aims/Objectives: Emotional distress is common among cancer patients even before anticancer treatment. The aim of this study is to understand the clinical characteristics related to emotional distress during that period.

Methods: Patients visited a cancer center with initial diagnosis of cancer, have not yet undergone anticancer treatment were enrolled. Demographic data, sites of cancers, initial staging, and past medical history were recorded. Physical symptoms were assessed by M.D. Anderson Symptom Scale. Global functional performance assessed by Karnofsky Performance Scale (KPS). Quality of life (QOL) was assessed by Functional Assessment of Cancer Treatment-General (FACT-G). Emotional distress was evaluated using Hospital Anxiety and Depression Scale (HADS). Depression sub-score of HADS more than 7 was considered to have significant emotional distress.

Results: A total of five hundred and eleven patients (173 men and 338 women) were enrolled, constituted by breast cancers (38.9%), head and neck cancers (24.7%), gynecological cancers (20.7%), and hematological cancers (15.7%). About one third of patients (30.9%) had significant emotional distress. They showed much more severe physical symptoms and poorer functional performance (KPS: 83.1±11.7 vs. 88.9±8.8, p<0.05), or poorer QOL than who did not so distressed. There is no significant difference in gender, age, sites of tumors, or stages of cancers between two groups.

Conclusion: One third of cancer patients who just knew the diagnosis suffered from emotional distress while waiting for treatment. More severe physical symptoms, poorer global functional status, and poorer QOL were related to higher emotional distress.

2. Tatiana D. Dmitrieva, Professor, MD, dmitrieva@mail.ru
3. Ludmila L. Drikina, Dr., MD, ldrikina@mail.ru

Aims and objectives: Domestic violence is a burning problem in Russia. Recent sociological studies suggested that violence against women takes place in one out of the four families in Russia. The main purpose of this research was to find out origins of crimes of violence of women who are themselves victims of domestic abuse.

Materials and methods: Research has been carried out on the basis of psychiatric an forensic psychiatric assessment of 20 women who were exposed to prolonged physical and psychological abuse by their husbands. All women of the cohort had committed crimes of violence - murders and attempted murders of their husbands.

Results: Domestic violence against women results in long term mental health problems. Clinical assessment of women has revealed different depressive symptoms, fear, anxiety, low self-esteem, sexual dysfunction, eating problems, obsessive-compulsive disorder, post-traumatic stress disorder, drug abuse. Women underwent forensic psychiatric assessment as they had committed homicides of their husbands and partners whose violence tended to escalate in frequency and severity. In the relatively new Criminal Code of Russia (1997) article 22 introduces the defense of diminished responsibility. It is important to note that because of its flexibility the plea of diminished responsibility has largely replaced the plea of "not guilty by the reason of insanity" for battered women.

Conclusions: The study reveals that psychological traumatization and victimization of women may be the cause of criminal aggressive behavior. The data show the necessity of domestic violence prevention by legal provisions and multidisciplinary research with the participation of psychiatrists, psychologists, human right advocates.

1. Margarita A. Kachaeva¹, Professor, MD, mkachaeva@mail.ru
2. Tatiana B. Dmitrieva¹, Professor, MD, dmitrieva@serbsky.ru
3. Ludmila L. Drikina¹, Dr, MD, ldrikina@mail.ru

Objectives: Researches on female offenders had indicated a high degree of psychiatric morbidity among women. The main purpose of the study is to ind out the origins of mental disorders and criminality in women.

Method: A cohort of 42 females with diagnosis of personality disorder was examined. All of them had committed crimes of violence.

Results: In the majority of the sample women had a previous history of psychiatric admissions (child and adolescent units). The retrospective review revealed that the majority of women in their child-

hood were exposed to emotional, physical and sexual abuse in their families. Results point out that maltreatment distort personality formation and social adjustment and contribute to mental disorders and criminal behaviour in adulthood.

Conclusion: The research shows that child and adolescent abuse influence psychiatric disorders in childhood, adolescence and adulthood and criminal behaviour in females. This findings may be used as prognostic indicators of aggression in female patients.

THE MOST SEVERE SOMATIC DISORDERS TREATED WITH EXCITALOPRIM

INSTITUTIONS
1. Hospital Dr Laza Lazarevic, Belgrade, Serbia and Montenegro

AUTHORS
1. Sanja Kaludjerovic¹

According to a report by the Clinical central of Belgrade (oncology, immunology, endocrinology departments) almost all patients treated for cancers, AIDS, Hashimoto tyreoiditis, colitis ulcerosa, experience episodes of persistent depression. Which is the most terrible moment? The moment patients hear their diagnosis? The moments when they suffer while getting chemotherapy, radiotherapy? The moment they become isolated expecting recurrence of disease? The moments when their relatives give upon them? The moment when mirror reflected damaged body, face? All of these moments. All of them are terrible, full of pain, and fear of death. In my study, I followed results the excitaloprim treatment on 30 patients (20 females, 10 males, age 20±7 years old). one women has AIDS diagnosis 20 persons have dg of cancer (colon, breasts) 4 persons have Hashimoto tyreoiditis One man hardly survive infarctus myocardii One man colitis ulcerosa 3 persons have insulin depend diabetes mell with complications Using Hamilton's scale for depression and Beck's scale they got the worst number of points on 24 items. 20 patients got 20 mg excitaloprim pro die another 10 patients got 10 mg excitaloprim pro die. After 2 months, follow up study showed that all patients felt better despite their hopeless diagnosis. On Hamilton's scale and Beck's scale still show statistically important improvement. They began to smile/they got a hope/ With supportive psychotherapy, conclusion are that excitaloprim show important result for better quality of life, getting life and hope back.

MENTAL HEALTH SERVICE USERS AND CARERS AS EXAMINERS FOR ROLE-PLAY SCENARIOS ON STIGMA AND DISCRIMINATION

INSTITUTIONS
1. Institute of Psychiatry, King's College London, Health Service & Population Research, London, United Kingdom
2. The George Institute for International Health, Population Health Research & Neurological/Mental Health Division, Sydney, Australia

AUTHORS
1. Aliya Kassam\(^1\), Miss, BSc (Hons), MSc, aliya.kassam@iop.kcl.ac.uk
2. Nick Glozier\(^2\), Dr, PhD, nglozier@george.org.au
3. Morven Leese\(^1\), Dr, PhD, m.leese@iop.kcl.ac.uk
4. Graham Thornicroft\(^1\), Professor, PhD, g.thornicroft@iop.kcl.ac.uk

Objective: To assess whether service user and carer assessments of role-play scenarios in undergraduate psychiatry education are valid and reliable measures of stigma and discrimination.

Methods: A professional role-player played the role of a service user or carer with which the medical student was instructed to conduct a history taking. The scenarios were assigned to n = 68 medical students and video-recorded. The role-play assessment, based on an Objective Structured Clinical Examination (OSCE) station exam with elements measuring stigma and discrimination was completed by the role-player and by a group of service users (n=2) and carers (n=2). Scores between role-player, carers and service users are compared.

Results: The validity and reliability (internal consistency, test-retest and inter-rater reliability) of the assessments as measures of good communication skills as well as stigma and discrimination in tomorrow’s doctors will be discussed. Implications for service user and carer involvement in examination of undergraduate psychiatry in medical education will also be discussed.

Conclusions: The involvement of service users and carers in medical education enhances the development of clinical reasoning, communication skills, and fosters accurate knowledge, attitudes and behaviour towards people with mental illness. Valid and reliable tools that are feasible for service users and carers to examine medical students should be implemented into the assessment procedures of the medical education curriculum.

AUTHORS
1. Magdalini Katsikidou\(^1\)
2. Maria Samakouri\(^1\)
3. Aikaterini Arvaniti\(^1\)
4. Miltiadis Livaditis\(^1\)

Aim: Some studies claim that there is a high prevalence of victimization among individuals with psychotic disorder. The aim of the present study is to compare rates of victimization between psychotic patients and healthy control group in the Region of Thrace- North Greece.

Method: We translated and adapted the National Crime Victimization Survey Questionnaire, for the needs of the present study. We interviewed 100 psychotic patients and 100 healthy controls. The two groups were matched concerning gender, age, educational status.

Results: 65% of people with psychotic disorder and 57% of the healthy controls reported at least one act of victimization against them during the last 12 months. A significantly higher proportion of the patients reported theft (23% vs 10% \(p=0.21\)) and assault (34% vs 11% \(p=0.001\)) against them.

Conclusion: There are indices that patients suffer higher rates of victimization considering several forms of delinquent acts.

A FRACTAL MODEL FOR PSYCHIATRIC DIAGNOSIS

INSTITUTIONS
1. UC Davis School of Medicine, Department of Public Health, Davis, California, United States
2. American University - Central Asia, Psychology Program, Bishkek, Kyrgyzstan

AUTHORS
1. Patrick Marius Koga¹, Dr., MD, pmkoga@ucdavis.edu
2. Elena Molchanova², Dr., MD, molchanova_e@mail.auca.kg

Aims/Objectives: Modifications in the connoted (classification systems) do not mirror the real changes in denoted (patient's mind); they mostly serve social functions such as recording and reimbursement. The authors hypothesized that if mental disorders and their corresponding semiotic fields could be identified as fractal constructs, then a subsequent fractal reorganization of the psychiatric taxonomy could provide clinicians with higher predictive power for better diagnosis, prognosis, and therapeutic decisions.

Method: The study has applied Benoit Mandelbrot's principles of fractal geometry to the taxonomy of psychopathology [1]. The authors have comparatively analyzed the syntax, semantics and pragmatics of two classification systems (DSM & ICD in their different versions) and then fractally reorganized the semiotics of mental disorders within the 3-D system of coordinates of a non-integer Hausdorff dimension in which the psychiatric patient's condition is to be plotted and monitored.

Results: The authors have created a novel, fractal model for the taxonomy of mental disorders which identifies the transformational vectors inside each spectral continuum of psychopathology and the connections interwoven across the various spectra. The model allows clinicians to shift from the static, categorical descriptive approach of DSM-IV-TR and ICD 10 to a dynamic, fractal taxonomy that holds more relevance for clinical practice.

Conclusion: This fractal model has the potential to optimize the effectiveness of psychiatric education and care by predicting more accurately the probability of qualitative and quantitative changes in a patient's condition.

The combination of mobile devices, wireless technologies and medical information systems changes concept of a workplace of the doctor, allows to work in any point of a planet, irrespective of distance up to a source of the information. The basic mobil resources are: - The Internet medical bases; - Baseses patients - access to out-patient cards and archives of case records, results of laboratory researches, etc. - The help information.

In Rehabilitation & Diagnostic Center the project of mobile access on base communicators is developed. In modern communicator compact Internet - station and phone are incorporated. It is practically high-grade minicomputer with powerful processor and great volume of operative memory. Built - in VGÀ the videocamera is intended for carrying out of videoconferences. Access to medical base of establishment can be carried out through the Web a server which can be located as directly in establishment, and somewhere on the Internet. The web - server with SQL base should provide:
- Access through the password to the database from any geographical place;
- An opportunity to look through and bring record;
- An opportunity to form the important information after which entering, to the addressee it is sent E-mail notice or SMS-message on the information which have appeared for it. At presence of such mobile medical communication access from any place to medical information system of establishment is possible. Employees can correspond by e-mail, ICQ or SMS, to communicate on visual communication through Skype. Mobile communication is simply irreplaceable for emergency transfer of the medical information.

AUTHORS
1. Uriy E. Liakh¹, Dr., Proff., rdckonst@mail.ru
2. Oleg A. Panhcenko², Dr., Proff., rdckonst@mail.ru
3. Victor G. Antonov³, rdckonst@mail.ru

Primary goals Medical Information System can be formulated briefly as follows: preparation, storage and the analysis of the information necessary for medical-rehabilitation, diagnostic, administrative and managerial processes, research and educated-methodical work, and also communication with other organizations and world databases. In Rehabilitation & Diagnostic Center more than one year is maintained the information system " Polyclinic " developed by Open Company "MedSystem", Kiev. The system answers the majority of the listed parameters, but is constructed more by a principle of the centralized postinput of the information by operators, instead of is direct in cabinets medical personal, that imposes the certain restrictions at its use. The basic source of the information on a state of health of the patient is the coupon of the outpatient patient f.025-6/o, magazines of reception of doctors, log-books of the carried out researches. During operation, the system functioning by a file - server principle, has shown high reliability and uninterrupted operation in work. Doubtless "plus" of system is the opportunity to carry out the all-round analysis of work and to receive the statistical reporting under all required official forms. After the certain time interval benefit of the electronic case record was showed: an opportunity of fast search of the patient in a database, viewing of all previous information on the patient. On the basis of operating experience of the diagnostic block of system by us technical requirements to an automated workplace "Functional diagnostics" are developed, called to remove lacks of system of this part.

QUALITY OF LIFE AFTER BARIATRIC SURGERY

INSTITUTIONS
1. Medicine and public health school, Psychiatry, Salvador, Brazil

AUTHORS
1. Manuela G Lima¹, Dr, PhD, limamn@terra.com.br
2. Ricardo AM Motta Filho¹, Mr., limamn@terra.com.br

Background: The most effective treatment for morbidly obesity has been the bariatric surgery. It is important assess the quality of life (QoL) and not only the weight loss after surgery. The aim of this study is assessing the QoL of the patients who underwent bariatric surgery.

Methods: The instrument used for assessment was the BAROS. Ninety-three patients were included in the sample. They were divided in 5 groups according to the time after surgery. The division made was the following: patients with 1 to 3, 4 to 6, 7 to 12, 13 to 24 and with 25 or more of time after surgery.

Results: An Excellent result was found with a mean score of 6.46. The mean time after surgery was 13.17. Between women, the married was majority. The men majority was single. The BAROS score increased from the group 1 (4.31) to the 5 (7.75). The excess weight loss increased from group 1 to 4 but reduce between 4 and 5 groups.

Conclusion: The patient's QoL after bariatric surgery increases even in the first months and continuous increasing until after 2 years. The married women underwent the surgery more than others. The single men are the most operated. The excess weight loss increases from 1° to 24° month post surgery but has a reduction after 25 months.

EASTERN SPIRIT, EASTERN WAY: CHINESE CULTURAL-BASED ART THERAPY GROUP FOR OUTPATIENTS WITH CHRONIC MENTAL ILLNESS

INSTITUTIONS
1. Cheng Ching Hospital, Psychiatric Division, Taichung, Taiwan Republic of China

AUTHORS
1. Chin-Ming Liu¹, Dr., MD, kmliu@ms8.hinet.net
2. Jheng-Yi Lin¹, Mr., uniyam@gmail.com
3. Jia-Lin Sheu¹, Ms./MA, art_heal@yahoo.com.tw

Objectives: Western researches and clinical works have approved the effectiveness of adopting art therapy as a treatment methodology for adults with psychiatric diagnoses. This paper reports the benefits of an art therapy group based on Chinese cultural principles as a part of day treatment program for outpatients with chronic mental illness in Mid-Taiwan area.

Methods: The group sessions were conducted twice a week within one month. Specific art projects, such as Chinese ink paintings and calligraphy, were applied in the group in order to promote opportunities for patients experiencing mindfulness process and Chinese philosophy of well-being.

Results: Case examples illustrate the clinical effectiveness including reduction of anxiety and anger, improvements in emotional self-efficacy, increase of self-initiation and social interaction. Other specific changes that improved patients’ quality of life are also highlighted.

Conclusions: The findings in this report suggest that adopting Chinese cultural-based art therapy group in day treatment program is beneficial for outpatients with chronic mental illness.

DEPRESSIVE SYMPTOMS AND QUALITY OF LIFE AMONG COMMUNITY ELDERLY

INSTITUTIONS
1. Institut Català de l’Enveliment. UAB., Spain
2. Universitat de Lleida, Spain

AUTHORS
1. Ramona Lucas Carrasco¹, Dr., PhD, Ramona.Lucas@uab.es
2. Jaume March², Dr, PhD, jaume.march@cmb.udl.cat
3. Antoni Salva³, Dr., MD, antoni.salva@uab.cat

Objective: Depressive disorders are common in old age; they have a negative impact on Quality of Life (QoL). Our aim was to investigate depressive symptoms and their impact on QoL among elderly living in Catalonia, Spain.

Methods: We studied a cross-sectional random sample of 2,500 dwelling community elderly. Information collected was: sociodemographics; perception of health; a list of comorbid conditions; depressive symptoms (GDS-15) and QoL (WHOQOL-BREF).

Results: One quarter of the sample had significant depressive symptoms (GDS≥ 5). Compared to men, female had higher GDS-15 scores (p<0.001) and more severe symptoms (p<0.05). Significant symptoms were twice (CI 95%: 1.7-2.5) as common in the younger group (65-79 y.o) compared to the older group (≥80y.o.). Controlling for chronic conditions, as the GDS-15 score increased, the risk of feeling unhealthy also increased: OR: 2.2 (CI 95%:1.7-2.9) for mild depression; 4.5 (CI 95%: 3.1-6.7) for moderate and 6.0 (CI 95%: 4.2-8.5) for severe depression. Only 69.4% of those with significant depressive symptoms received treatment for depression. In relation to QoL, we found significant differences among depression groups; as severity of depressive symptoms increased, QoL scores decreased in all WHOQOL-BREF domains.

Conclusion: Prevalence of depressive symptoms was similar to that reported on other community surveys; higher rates among females were consistent. Depression in the elderly is a condition that can benefit from different interventions, thus, improving their QoL.

QUALITY OF LIFE AND DEMENTIA: PATIENTS VIEWS

INSTITUTIONS
1. Institut Català de l’Enveliment. UAB, Barcelona, Spain

AUTHORS
1. Ramona Lucas Carrasco, Dr., PhD, Ramona.Lucas@uab.es
2. dr., phd, ramona.lucas@uab.es

Aims: Dementia is a syndrome characterized by a progressive global deterioration; it constitutes a major public health concern. Quality of Life (Qol) in Dementia is a more recent research area compared to other chronic diseases. Our objective was to study, using Focus Groups (FG), aspects that contribute to the Qol of people with Dementia.

Methods: This was a qualitative study, using FG with people with cognitive impairment and dementia. Participants were recruited from Day Centres and one Primary Care Centre in Barcelona, Spain. Subjects were asked to freely talk about areas and issues that were important to their Qol. After a free discussion, they reviewed the list of facets included on the existing WHOQOL-BREF measure and were asked if they had further comments. FG had 4-5 participants, lasted about one hour and all FG were audio taped. All participants signed the inform consent.

Results: Thirty subjects participated in six FG. Overall, in all FG subjects mentioned spontaneously all the facets included on the WHOQOL-BREF, but some differences were found between patients with cognitive impairment and dementia. Subjects with cognitive impairment were more productive than those with dementia. Family relationships, love, health, dependence, activities and home environment were the most frequently aspects mentioned. Memory problems, loneliness, anxiety, worries, feeling a burden were other aspects mentioned included on specific Qol measures for people with dementia.

Conclusions: People with mild to moderate dementia were able to inform about their Qol, these results were similar to those reported by other authors.

4. Dawit Wondimagegn, Dr., MD
5. Rita ‘Ihom’, Dr., MD
6. Sarah Stranks, Ms

Objectives: Psychiatrists play a key role in provision of comprehensive HIV care in developing countries. We conducted an online survey to understand psychiatrists’ perceived learning needs in HIV psychiatry.

Methods: We accrued a list of 604 psychiatrists in Sub-Saharan Africa. 469 successfully received the invitation to participate. The survey inquired about (i) demographic and professional information; (ii) knowledge, skills and attitudes; (iii) preferences for educational programming; (iv) barriers to learning. 5 Case examples were employed to elucidate information.

Results: 50 (10.6%) responses have been received, representing 7 countries. Worked settings were: 27/49 (55.1%) academic setting, and 27/47 (57.4%) general hospital. 14/43 (32.6%) received HIV psychiatry training in residency. 43/43 (100%) said they would attend an educational program in HIV psychiatry. The majority of respondents reported adequate knowledge/skills in basic HIV medicine and providing emotional support to patients after receiving seropositive results. Areas of perceived inadequate knowledge/skills included: drug interactions, evaluating mental health side effects of medications, and working effectively with traditional healers and internists. Barriers to learning included: limited access to continuing education, time limitations and perception of HIV as only a physical illness. Most desired learning modalities included: workshops and small group interactive sessions. Web-based learning was not highly desired. Lack of computers, slow and inconsistent internet connection and lack of interpersonal connection in the learning process were identified as potential limitations to internet-based educational programming.

Conclusions: Respondents report a high desire for more training in HIV Psychiatry, particularly in the areas of drug interactions and working effectively in care systems.

Depression is the commonest psychiatric morbidity worldwide. According to the WHO, depression will be the fourth leading cause of disability worldwide by the year 2010. Depression in women present unique features, problems, unmet needs and possibly new and/or novel therapeutic approaches. Beside neurobiological exclusivity, there may also be ethnic/sociocultural/catamenial substrates contributory to this differentiation. Whether the population of women who receive a diagnosis of depression is a tip of the iceberg, specially in the developing countries, is a concerning point to ponder. The present study discusses these issues and also the phenomenon of depression as part of “bipolar spectrum disorder” in 100 female patients in Kolkata, India which is possibly the first multicentreic study of bipolar spectrum disorder among women in India employing the Bipolar Spectrum Diagnostic Scale.

THE ROLE OF THE FAMILY IN CASES OF CRIMES COMMITTED BY PSYCHIATRIC PATIENTS

INSTITUTIONS
1. Psychiatric Hospital of Thessaloniki, Department of Forensic Psychiatry, Thessaloniki, Greece
2. Psychiatric Hospital of Thessaloniki, A Unit for short-term hospitalization, Thessaloniki, Greece

AUTHORS
1. Maria Markopoulou
2. Olga Georgiadou, spok15@otenet.gr
3. Ioannis Pantoularis
4. Iordanu Dini
5. Neophytos Theodorides
6. Konstantinos Bobotas

Aims/Objectives: The majority of the investigators suggest that, especially for the schizophrenic patients, at the time they commit the crime, they do manifest active psychotic symptomatology. Taking these findings into consideration we studied our patients’ case files in order to find out the role of the family in the course of the illness from its onset and on.

Methods: 50 patients, 47 males and 3 females, who have committed crimes, were found irresponsible due to mental illness and are now hospitalized in the Psychiatric Hospital of Thessaloniki, were studied. They are provided with treatment and are subject to compulsory detention.

Results: In most of the cases the patient’s family only observed the onset or the relapse of the disease. Only 37.5% of the manslayers had psychiatric support prior to the perpetration of the crime. 38 of our patients (76%) had positive symptomatology with delusions which is associated with more serious crimes: from 28 manslaughters 21 had positive symptoms and from the group with positive symptoms 73% either committed or attempted to commit homicide. As regards to the crime, in cases of manslaughter the victims were members of the family in 75%.

Conclusions: Our findings suggest that the contributory role of the family is of great importance both in the appearance and course of psychiatric disorders, especially when the risk of violence is high. So the family environment can either serve as a protective matrix or as an opportunity for aggressive interactions affecting violence risk in complex ways.

THE FIRST FORENSIC PSYCHIATRY EXPERT’S REPORT IN SERBIA

INSTITUTIONS
1. Institute for psychiatry "Dr Laza Lazarevic", ambulance, belgrade, Serbia and Montenegro

AUTHORS
1. Dragana I Mrakovic, Mrs, Dr, MD, kasanski@eunet.yu

Background: The history of medicine in Serbia has begun with the foundation of hospitals within Monastery of Hilandar and Studenica in XII and XIII century. In these hospitals there were special departments for mentally ill people. The first hospital on the Balkans for mentally ill people «Dr Laza Lazarevic» was founded in Belgrade in 1862.

Goal: The purpose of this abstract is to present the first forensic psychiatry expert’s report in Serbia from 1863. This expert’s report took place in the Hospital «Dr Laza Lazarevic».

Methodology: Description of forensic expert’s report of patient K. Dj. She has committed homicide after epileptic seizure. The result of the expert’s report was compulsory treatment in this hospital.

Conclusion: It is believed that with this first expert’s report in the history of Serbian medicine the era of new medical discipline has begun. That discipline is forensic psychiatry.

Key words: the history of Serbian psychiatry, expert’s report.

SUBJECTIVE WELL-BEING OF PATIENTS ON AMISULPRIDE

INSTITUTIONS
1. F. D. Roosevelt Hospital, Department of Psychiatry, Banská Bystrica, Slovakia
2. Pedagogical Faculty of M. Bel University, Department of Psychology, Banská Bystrica, Slovakia

AUTHORS
1. Ludvík Nábělek¹, Dr., PhD., psychiatria@nspbb.sk
2. Ján Vongrej¹, Dr.
3. Eva Nábílková², Mrs.

Objectives: Outcome of schizophrenia depends on early treatment and successful prevention of relapses. The poor compliance of antipsychotic treatment is most frequently conditioned by undesirable side-effects of drugs. However, little is known about the subjective experience associated with long-term antipsychotic treatment.

Methods: In non-intervention open-label observational study the data from 492 patients in acute phase of schizophrenia treated with flexibly dosed amisulpride were collected at baseline, week 4, week 8, and week 16. Patients well-being was assessed using 20-item version of SWN (Subjective Well-being under Neuroleptics) scale, and disease severity with the Clinical Global Impression - Severity of Illness (CGI-S), and Clinical Global Impression - Global Improvement (CGI-I) scales. In addition, safety and tolerability were monitored throughout the study.

Results: The subjective well-being of patients on amisulpride treatment (mean endpoint dose 490 mg/day) was significantly improved (total score of SWN, as scores in subscales of self-control, physical functioning, mental functioning, emotional regulation, and social integration). Amisulpride treatment led to a significant reduction in disease severity.

Conclusion: The better safety and tolerability profile of amisulpride with the benefits on negative symptoms and cognitive impairment improves the subjective well-being of patients with schizophrenia as a major predictor of long-term clinical outcome.

P-04-263
OBSTETRIC COMPLICATIONS AND POSTPARTUM PSYCHOSIS: A FOLLOW-UP STUDY OF 1.1 MILLION FIRST-TIME MOTHERS BETWEEN 1975 AND 2003 IN SWEDEN

INSTITUTIONS
1. Karolinska Institute, Center for Community and Family Medicine, Huddinge, Sweden

AUTHORS
1. Anna Nager¹, MD, anna@nager.se
2. Kristina Sundquist¹, MD, PhD
3. Vania Ramírez-León¹, MD, PhD
4. Leena-Maria Johansson¹, MD, PhD

Aims/Objectives
Postpartum psychosis is a severe psychiatric disorder that leads to hospital admission in about one woman per 1,000 deliveries. It coincides with the vulnerable period associated with becoming a mother and may, if untreated, lead to suicide and infanticide. Some risk factors for postpartum psychosis have been identified in previous research, such as primiparity and previous psychiatric disorder. Knowledge on how postpartum psychosis is related to obstetric factors might be helpful in the clinical risk assessment of postpartum psychosis. The aim of this large-scale follow-up study was to examine the association between postpartum psychosis and certain pregnancy and delivery complications and other obstetric variables, after adjustment for age, year of delivery and previous hospitalization for psychiatric disorder.

Method
1,133,368 Swedish first-time mothers were included during a 29-year period yielding 1,413 hospitalized cases of postpartum psychosis. Several obstetric variables were analyzed separately after adjustment for possible confounders.

Results
Respiratory disorder in the neonate, severe birth asphyxia, preterm birth, caesarean section, perinatal death and SGA infant were associated with an increased risk of postpartum psychosis. After adjustment for previous hospitalization for psychiatric disorder only preterm birth and acute caesarean section remained significant risk factors for postpartum psychosis (relative risks were 1.20 and 1.31, respectively). The relative risk of postpartum psychosis among first-time mothers with previous hospitalization for psychiatric disorder was increased more than 100-fold.

Conclusion
Careful clinical risk assessments of postpartum psychosis are crucial among women with a history of psychiatric disorder whereas obstetric variables have a minor importance.
P-04-264
LEVEL OF MENTAL HEALTH IN WOMEN WITH GYNECOLOGICAL PATHOLOGY

INSTITUTIONS
1. Mental Health Research Institute, Preventive Psychiatry Department, Tomsk, Russian Federation

AUTHORS
1. Renata F. Nasyrova1, Mrs., niipz@sibmail.com

We have examined 50 women of reproductive age (from 18 till 45 years), mean age has constituted 28.4±5.2 years, under treatment at a gynecologic hospital. All the examined exhibited depressive symptoms (13.5±4.1 scores according to HADS). Most women noticed interrelationship of worsening the depressive mood with origin of pain symptoms on the side of reproductive system. Anxiety and depression in examined female patients were as a rule comorbid. Mean group index testified to predominance of moderate level of anxiety in these female patients and achieved 23.2±4.1 scores according to HAS. Basic fears of women were associated with further ability to reproduction after experience of a gynecologic disease. Formed mental disturbances worsening severity of the state of women, decreasing adaptive possibilities, essentially worsen quality of life and efficacy of therapy. Thus, obtained results demonstrate presence of interrelationship of gynecological and mental manifestations in examined women. Combination of anxious and depressive disorders results in masking the depressive manifestations worsening course and prognosis of the disease. It should be especially noticed that leading strategic task of diagnosis and treatment of borderline neuro-mental disorders in gynecologic practice is identification of individual clinical model of disease aimed at forming the differentiated scheme of gradual tactics of medical assistance rendering depending on individual clinical picture of the illness. This stresses once again necessity of complex approach to assessment of state of the woman in a gynecologic hospital.

DIFFERENT WAYS OF EVALUATING EFFECT OF TREATMENT IN PATIENTS WITH SCHIZOPHRENIA TREATED INVOLUNTARILY

INSTITUTIONS
1. First Faculty of Medicine, Charles University, Department of Psychiatry, Prague, Czech Republic
2. Faculty of Medicine Carl Gustav Carus, University of Technology, Department of Psychiatry and Psychotherapy, Dresden, Germany

AUTHORS
1. Alexander Nawka1, Dr., MD, nawka@seznam.cz
2. Jiri Raboch1, Prof., MD, PhD
3. Lucie Nawkova1, Dr., MD
4. Thomas W. Kallert2, Prof., MD, PhD

OBJECTIVES: There are various approaches to assess the improvement or impairment of patients with schizophrenia treated involuntarily. The most common one is the evaluation of psychopathology. Recently, experts in the field claim that also other aspects like social functioning, subjective quality of life and satisfaction with treatment should be taken into account.

METHODS: 119 involuntary patients, who met the criteria for an F2 disorder according to the ICD-10 at the admission were included. They were assessed three times, in the first week and at the end of first and third month after admission. Psychopathology was assessed by Brief Psychiatric Rating Scale (BPRS), social functioning with Global Assessment of Functioning Scale (GAF), subjective quality of life was measured with the Manchester Short Assessment of Quality of Life (MANSA) and satisfaction with treatment with selected items from Client’s Assessment of Treatment (CAT).

RESULTS: The outcome was defined as a change in the total scores between first and third observation. We have found significant improvement in BPRS (T1 50.3±12.7, T3 28.4±7.8;p<0.001), GAF (T1 29.8±12.8, T3 63.6±17.1;p<0.001) and CAT(1 item)(T1 6.86±3.11, T3 7.64±2.53;p<0.05) scores, but no difference in MANSA (T1 56.2±10.8, T3 56.6±8.7; p>.39) score.

CONCLUSIONS: At variance with the results describing significant improvement in psychopathology, social functioning and satisfaction with treatment, quality of life seems to be more resistant to treatment. Considering quality of life as crucial outcome variable this findings indicate that among other aspects evaluating effect of treatment, more attention should be paid to this more complex one.

2. Olivera Zikic², Dr, MD, goni@eunet.yu
3. Suzana Tasic-Golubovic³, Dr, PhD, goni@eunet.yu

Near 25% of chest pain patients who refer to cardiologist do not have coronary disease or any other organic cause. Psychogenesis of their symptoms is often unrecognized so, they are treated neither cardiological, nor psychiatric.

Method: We have evaluated 30 nonorganic chest pain patients with 30 coronary patients in regard their sociodemographic characteristic, stressful life events, level of anxiety and depression and presence of psychiatric disorder. We have used SCL-90 R, M.I.N.I, Hamilton Anxiety and Hamilton Depression Scale, Holms-Rahe Scale of life events. Non organic patients were predominant women, age under 40, who have had their job lost or death in the family. Panic disorder was present at 8 patients, General Anxiety disorder at 5, and Somatoform disorder at 10 patients in these groups. Coronary patients had Minor depression disorder at 4 patients, and General Anxiety disorder at 2 patients. Level of anxiety (Hamilton Scale, SCL-90 R) somatization (SCL-90 R) and global distress (SCL-90 R) was significantly higher in nonorganic chest pain patients compared with coronary patients.

Conclusion: Cardiologists should consider psychogenesis of unexplained chest and recommended psychiatric evaluation and treatment in the early phase of disorder. Careful cardiology follow up is also recommended for these distressed patients.

ROMAINE BROOKS - CREATIVITY AND DESTRUCTIVENESS OF THE PARANOID PROCESS

INSTITUTIONS
1. Faculty of Medicine, Psychiatric Clinic, Nis, Serbia and Montenegro

AUTHORS
1. Julijana M Nikolic-Popovic, Dr, PhD, lulap@ptt.yu
2. Snezana D Manojlovic, Dr, PhD, ttomas@eunet.yu
3. Suzana D Tosic-Golubovic, Dr, PhD

In the paper biographic data and work of the American-British painter Romaine Brooks (Beatrice Romaine-Goddard, 1874-1970) are brought into correlation with adaptive, creative but also with the destructive potentials of the paranoid process. Highly pathological constellation of the family relationships and childhood marked by them determined the pathological model of the nuclear introjective configuration, and, later, a specific pattern of personal development. Response of the personality to the traumatic experiences is given parallelly in the structuring of the way of relating to others, in sexual identity (open homosexuality) and in particular creative potential (Gabriele D’Annunzio considered her “the most profound and wise orchestrator of grays in modern painting”). Such response is analyzed in detail through the development of the paranoid process. Superbly a portraitist, capable to discover the inner being of her models, Romaine Brooks in 1925 cedes with this kind of work. From 1930 to 1935 she made about 100 drawings using the technique of “automatic painting”, for which she considered that “evolved from the subconscious...without premeditation”. After 1935 she stopped to paint. Change of the way of life and work reflects the beginning of the destructive activity of the paranoid process all the way to the delusional paranoid construction. Attempt of self-curing through constructiveness and freely choosing of life forms was destroyed by basic destructiveness of the deepest nucleus of the personality, the invincible introject of the aggressor.

“Action T4” was the first mass manslaughter of people committed by the Nazi country. That action was also called ‘euthanasia’ of the handicapped people. Its beginning fell on in October 1939. The annihilation of patients was carried out in the psychiatric hospitals in Zwiecic, Kocborów, Poznan in Fort VII, Owinskie, Dzickanka, Koscian, Kocianowka near Lodz, Gostynin, Bojanow, Zrem. Some of medical and nursing staff were dismissed, medicine taking was limited and there was a ban on discharging patients from hospitals introduced. For extermination they used the pharmacological medications and the gas chambers located on cars were applied for the ill extermination. The psychiatric hospital in Kocianowka was the place where the mobile gas chambers were used for the first time in December 1939 or in March 1940. Over 629 handicapped people and blind children were slain there. It has been estimated that more than twenty one thousand of the handicapped people were murdered on the occupied grounds.

About 350 doctors took part in the action of the handicapped manslaughter in the Reich and the incorporated terrains. Among them there were also university professors among them. Some time later many of them committed suicides, few were tried and in some cases the punishment was mitigated.

Key words: euthanasia, extermination, psychiatric hospital

**RETROSPECTIVE STUDY OF PMDD AND POSTNATAL DEPRESSION: PRELIMINARY SURVEY**

**INSTITUTIONS**
1. Mie University, Centre for Health, Tsu, Japan

**AUTHORS**
1. Tadaharu Okano, Dr., PhD, okano@ab.mie-u.ac.jp

**AIMS:** There can be seen some women with postnatal depression (PND) developed into premenstrual dysphoric disorder (PMDD) after delivery. Onset age of PMDD reported is peak from late twenties to early thirties. This period seems to be corresponding with reproductive period. However, the relationship between PND and the new episode of PMDD is unclear. This preliminary study investigates to determine whether postnatal depression is risk factor for such a PMDD or not.

**SUBJECT:** Women (n=46) with first postnatal depressive episode were selected for 5 years in Mie University Hospital and followed at least after 1-3 year after parturition. Their average age is 31.83±3.92. Of all, 35 diagnosed major depression and 11 as minor depression according to DSM-IV.

**METHODS:** A structured diagnostic interview was performed within few months after delivery to assess for the presence of PMDD.

**RESULTS:** Of 46 women with postnatal depressive disorders, 34.8% reported severe premenstrual symptoms including PMDD. Past premenstrual tension syndrome, and primiparae, were also found to be significant risk factors for PMDD.

**CONCLUSIONS:** PMDD after delivery is common in women with PND, and there being the pathogenesis of psycho-endocrine relationship between mood disorder and PMDD after postpartum period.

**LIMITATIONS:** While the study design is limited by the retrospective assessment of risk factors, a control study is needed to determine whether PND is associated with progression to PMDD or not.

**MALIGNANT TUMOR AND PSYCHOLOGICAL CRISIS IN PATIENT**

**INSTITUTIONS**
1. Institute of Internal Medicine, Novosibirsk, Russian Federation

**AUTHORS**
1. Tat'yana G. Openko, nsk217@rambler.ru

The survival rate of cancer patients depends on their personal features very strongly.

**Objectives:** to study dynamics of psychoemotional conditions of patients during illness.

**Methods:** 136 patients (60 men and 76 women, in age 34-60 years, with malignant tumors) within 5 years were supervision of oncologist and psychologist. Psychological interview and testing on Spilberger scale, questionnaire CES-D and questionnaire 16PF have been lead. The psychological data have been analyzed after five years (52 persons has survived and 84 persons have died).

**Results:** It was revealed, that a high level of uneasiness, depression, angedonia, alexitymia, fixity and the feeling of faults, and also not constructive types of reaction to illness worsen the survival forecast. At all observable patients during disease came to light 2-4 psychological crises. The first crisis has been connected with diagnostics of a cancer. The patient receives to stress from diagnosing of cancer. Second crisis is connected with antineoplastic treatment. One more crisis can be connected with the advent of metastasizes or relapse of cancer. Suddenly found out metastasizes cause stronger stress, than gradual deterioration of a condition. The change of a psychological condition at the patient will be how much strong from the personal features depends. Often there is infringement of illness comprehension, «blockade of emotions». Last psychological crisis is connected with comprehension of hopelessness and comes shortly before death. The first crisis happens mainly psychogenic, the second - mainly somatogenic, the third and the fourth - psychosomatogenic. During each psychological crisis there are targets for psychotherapeutic influence.

1. Saeid Pahlavanzadeh¹, Mr, MSc, pahlavanzadeh@nm.mui.ac.ir
2. Nasrollah Alimohammadi², Mr, MSc, alimohammadi@nm.mui.ac.ir
3. Mohammad Hosein Soltani², Mr, MSc, soltani@yahoo.com

**Objectives:** Psycho-cognitive and physiologic signs of long term diseases affect various aspects of patients' life. Multiple sclerosis (MS) as a long-term life threatening disease can make acute disabilities affecting patients' life trend (1). Self care can well diminish the disease extension and complications; provides the patient with a better life quality and his family with a better coping ability against new conditions. So this study was carried out with the above title (2).

**Methods:** This study was quasi-experimental. Twenty eight MS patients referring to private and clinic of Isfahan Alzahra hospital were selected by convenient sampling. The subjects were asked to attend three educational sessions. After that, the subjects started self-care programs for three weeks and then psycho-cognitive and social function questionnaire was filled with the patients. The findings were analyzed through descriptive and inferential statistics.

**Results:** Findings showed a noticeable increase in mean score in psycho-cognitive (P<0.001) and social function (P<0.001) after self care program.

**Discussion:** The findings showed that self-care activities result to promoting of psychological and social functions, because participating of patients in self-care behaviors may lead to improving self-esteem and enhancing mood status and eventually promoting the quality of life. It is hoped that by formation of educational supportive associations for the patients, the patients can be provided with facilities of self care as well as a condition in which the patients themselves carry out their self care.

One of the goals of aggression against Bosnia and Herzegovina was deliberate infliction of physical and mental harm associated with high traumatization of victims, family destruction and its dysfunctions. Torture strategy in the frame of sexual slavery is characterized with compulsive pregnancy and forced motherhood with the aim to disable the personality of victim and destruct her family. It resulted in disrupted psychological condition of victim, followed by a strong emotional storm of shame, guilt, feeling of impurity and disgust, aggressive behavior towards child and oneself, suicidal latency and depression. Rape represented a part of military strategy, where the human sexuality had been used systematically with the purpose of ethnic cleansing, which is genocide, as any other type of massive destruction arms. For the first time in the history of warship, the rape is officially recognized as a war crime and crime against humanity in the case of Bosnia and Herzegovina, which was a turn point on the international legal level. In 1993, the paper titled as «Message to raped women» had been published by Ahmed Mesic, the Islamic-law judge from Tuzla, Bosnia and Herzegovina. In this letter, valuable guidelines are given on how to approach to the victims of those atrocities and what measures are to be taken in order to offer the quickest and effective help to the victims of those horrible crimes. It also facilitates short-term and long-term consequences on mental health of raped women, their children born from this action, their families and society in whole.

**Key words:** Rape, Genocide, Psychological Consequences, Message to Raped Women
A COMPARISON OF COMBINED VERSUS PHARMACOLOGICAL PSYCHIATRIC TREATMENT FOR DEPRESSION IN ONCOLOGIC PATIENTS

Oncologic patients show a high prevalence of affective disorders, having a negative influence on the patient health and deteriorating quality of life and, all it contributes to a worst evolution of the oncologic process. We present the preliminary results of the project FIS projects 050737 and 05/2062, in which we compare the effectiveness of a combined treatment (psychotherapeutic and pharmacologic) and a pharmacologic treatment, in oncologic patients on depression and quality of life. 768 Patients with colon, breast and lung not metastasized cancer, diagnosed of a depressive disorder (DSM-IV criteria) were selected. All participants completed the HADS questionnaire, confirming the diagnosis by obtaining a score over 7 using the Semi-structured Clinical Interview for DSM-IV (SCID). 115 of the subjects included scored 8 or over at the HADS depression subscale. 14.19% (109 patients) confirmed the diagnosis of depression. At the moment, there are 34 patients in the combined therapy group (21 already finished and are under monitoring). 28 patients are under monotherapy treatment (7 already finished and 11 quitted). 3 subjects were excluded due to the illness progress, 1 leaved. There are differences between both groups in some topics of the quality of life and in the way they face the illness. Coping anxiety and depression differs in both groups.

MENTAL HEALTH OF THE WOMAN IN THE MODERN SOCIETY

INSTITUTIONS
1. Ukrainian Engineering Pedagogics Academy, Faculty of Pedagogic & Engineering Psychology, Kharkov, Ukraine

In our society on the woman the big social-psychological loading lays, she should combine simultaneously role of the wife, mother, employer. There is a necessity for revealing psychological problems, research of a condition of mental health of women.

Objective: In total 210 persons of a female addressed for the psychological help with problems of personal character have been surveyed. Among them in the age of 20-25 years - 35 pers. (17 %), 26-35 years - 62 pers. (29,5 %), 35-40 years - 113 pers. (53,8 %). Of them working made 169 pers. (80,4 %), idle - 41 pers. (19,5 %).

Methods: Research was carried out with by use of techniques: «The Hospital scale of alarm and depression», scale by Zunge, «The Clinical questionnaire for revealing neurotic conditions».

Results: As a result of research at 172 (82%) women have been revealed various infringements: clinically expressed depression - 75% (129 pers.), the raised(increased) level of alarm - 56,3 % (97 Ge.), hysterical frustration - 20,3% (35 pers.), asthenia - 58,7 % (101 pers.), vegetative infringements - 89% (151 pers.), obsessive-fobical disorders - 26,7 % (46 pers.), at the others 38 (18%) - deviations from norm are not revealed.

Conclusions: In view of breadth prevalence of mental infringements among women, we came to the conclusion about necessity of creation of the psychocorrectional program and the primary preventive help which will consist in increase stress stability women, frustration tolerances, development of positive thinking, muscular relaxation and corporally - guided programs.

OSPDN - NATIONAL ORGANISATION OF RELATIVES OF MENTALLY ILL

INSTITUTIONS
1. OSPDN, Sympathea, Prague, Czech Republic

AUTHORS
1. Jana Poljaková, jpoljakova@seznam.cz

Introduction: About us

There exist a few non-profit organisations for relatives of mentally ill in Czech Republic: The oldest one „Ondřej” established in Prague on the beginning of nineties, „Amicus” Brno and key organisation „Sympathea” Prague and some regional organisations. („Šela” Kolín, „Felicitas” Pardubice and others.)

All of them endeavour the same: improving the uneasy life of their mentally ill children.

„OSPDN” was established as a national umbrella organization for all those aforementioned organisations, that OSPDN represent.

Abstract - OSPDN - National organisation of relatives of mentally ill

OSPDN represents the interests and activities of relatives in:
- regions
- the whole Czech Republic
- Europe - by cooperation with EUFAMI, Sympathea is a member of this European Federation of Associations of Families with Mental Illness

LEISURE AND MENTAL HEALTH FOR PSYCHOTIC PATIENTS: A QUALITATIVE STUDY

INSTITUTIONS
1. Bahian School of Medicine and Public Health (EBMSP), Psychiatry, Salvador, Brazil
2. Foundation for the Support of Research in the State of Bahia (FAPESB), Salvador, Brazil

AUTHORS
1. Milena Pereira Pondé, dr., md, PhD, pondem@terra.com.br

Aims: Quality of life is defined by indicators that measure the life patterns of a person or community in relation to an ideal model. Leisure is an important component of quality of life and a rehabilitation tool for chronic psychotic patients. The objective of this study was to evaluate the role of leisure in the life of schizophrenic patients. Methods: Semi-structured interviews were carried out. The interviews were recorded using mini-cassette recorders, the recordings were later transcribed and analyzed in two levels. Results: Interviews with patients and relatives indicate that sociability is an important value related to leisure activities for both groups. Deeper analysis, however, indicates that sociability is a culturally learned concept for psychotics and does not relate to their real needs. Improvement of symptoms and respect of individuality are more central to their well-being.

Conclusion: This study concentrated on the role of leisure in people’s life and its possible benefits on well-being. It is obvious that this is not a causal relationship but a relationship of values that are important locally, and it is clear that diversion can only be important to well-being when it is based on this relationship. Therefore, the characteristics that associate diversion with health are those representing the values that are meaningful to the people interviewed.

2. Jan Prasko\textsuperscript{1,2,3}

The interview is the principal means of assessment and case management in clinical psychiatry. Psychiatric interview differ form other medical interviews in the wide range of biological and psychosocial data which they must take into account, and in their attention to the emotional reaction of the patient and the process of interaction between patient and interviewer. The therapist-patient relationship developed during the assessment and evaluation of the patient.

Methods: To improve the practical skills in clinical management with patient we use follow steps in training with the students:
1) video presentation of the typical case of disorder (e.g. posttraumatic stress disorder)
2) short description of the psychopathology, diagnosis, etiopathogenesis a and treatment strategies
3) video presentation of first contact with the patient, assessment, evaluation and psychoeducation, eventually treatment strategies (e.g. exposure in imagination)
4) analysis of the main steps of the video presentation with emphasis to the structure of the interview, open questioning, empathetic listening and positive forcing or the patient
5) modeling or the approach with the group of students (leader plays a role of the patient and the participants practice the approach)
6) role playing in small groups of three students with video-monitoring their work
7) video-feedback and discussion of the advantages and disadvantages of the work of monitored group

Results: The students like these approach and evaluated it very high in the every year school training evaluation.

Conclusion: The using multimedia tools, role playing and video feedback can help developed practical skills of the students more, than classical approach of training.

QUALITY OF LIFE IN PARKINSON’S DISEASE:
A CORRELATIONAL STUDY

INSTITUTIONS
1. Hospital Magalhães Lemos, Porto, Portugal
2. Hospital Pedro Hispano, Porto, Portugal

AUTHORS
1. Rosa Quelhas\textsuperscript{1}, rosaquelhas@gmail.com
2. Manuela Costa\textsuperscript{2}

Introduction Parkinson’s disease (PD) is a chronic degenerative disease, with major impact in quality of life (QoL). Studies reported a 40% mean incidence of depression, and higher incidence of anxiety symptoms than in other chronic medical conditions. Authors intended to evaluate the impact of PD severity, anxiety and depression in QoL.

Methods Cross-sectional study with PD patients assessed at consultation for disorders of movement. Patients with atypical, drug-induced or vascular parkinsonism, dementia or relevant comorbidity were excluded. Assessment instruments were HoehnSF-36 and HADS scales. Statistical analysis was performed with NCSS.

Results Analysis included 43 consecutive patients. Higher severity of disease was significantly related with lower physical SF-36 scores, without psychological compromise. Spearman coefficients in HY stage 2 subjects (N=26) showed a negative correlation between HADS score and SF-36 score. Anxiety was significantly correlated with physical summary score. Multiple regression analysis revealed that HADS score was the most important predictive factor of QoL, followed by HY stage, both accounting for 42% of the variance of global QoL. Anxiety was a significant predictor of physical summary score.

Discussion This study revealed that anxiety had the highest impact, followed by depressive symptoms, in QoL. Anxiety correlated with physical QoL score, suggesting its subjective impact on physical fitness, and/or relationship with the neuropathological process of PD. Therefore, anxious and depressive symptoms must be routinely assessed in PD patients, in order to guarantee QoL optimization. In this context, HADS scale may be a useful tool to assess psychopathological, and perhaps dopamine deficiency, symptoms.

1. M. Beatriz M Quintanilla¹, Dr, MD, PhD, bquintan@up.edu.mx

Joan of Castile, was to inherited the most vast empire of her times. Married at 16 years old with Philip of Habsburg, went to live to Flanders, very far away from her home. When the arrangement of her marriage was made, nobody could guess that this young couple might be destined to become the kings of a fantastic empire which might embraced the largest territory ever seen under a same sovereign. Joan had to live as a just married young woman, in a strange court that had very different customs, language an weather from hers. Only the extraordinary love that she felt for Philip since the very first moment she met him, would made her cope. This love will become her savior and her shield but also her downfall. Keeping a jealous eye on her husband, who was all the time chasing other women, and suspicious of every woman around him, delusion found her way and mental illness l became her only companion for the rest of her life. Dead under strange circumstances in Burgos, Philip might have to wait patiently for a definitive rest while a mad Joan drift around for almost three years in procession behind his coffin in order to buried him in Granada. In this study, psychopathological analysis of Joan’s madness, as well as her personality reactions and interpersonal relations, is made from biographies and documents that have came up to us by renown historians. Retrospective and previous diagnosis are discussed under current diagnostic categories.

At a time in which proclaimed secularization, relativistic homologation and diffused reductionist naivety seem to have ambiguous ly blurred the boarders of revelatory experiences, the latter seem to maintain a core salience for a comprehensive anthropological understanding of both religious and psychotic modes of being. A series of self-descriptive sketches drawn from religious literature and clinical cases of prodromal schizophrenic subjects will be investigated, emphasizing formal analogies (i.e. semantical recurrences, imperative unescapability, passivity feeling, transformational value, perceived biographical hiatus) and qualitative discontinuities (i.e. transitive openness vs solipsistic structure, vertical vs eccentric displacement). Finally an attempt of phenomenological-psychopathological distinction between vertical spiritual experiences and idiosyncratic beliefs embedded in psychotic self-narratives will be proposed on the basis of such descriptive organizers.

AUTHORS
1. Lucia M Ribeiro, Dr, MD, luciarib@gmail.com
2. Raquel R Silva, Dr, Md, raqrsilva@iol.pt

The authors work in a liaison service in a central general hospital having an organized response to all women undergoing a mastectomy in that hospital. In this paper we describe a two year experience with a model of supportive group therapy for mastectomyzed women in different phases of the disease and different moments of group growth. The purposes of our approach are firstly create an empathetic space where women can express themselves and develop a supportive network, allowing them work to grief over losses, aiming to improve their coping strategies and general well-being. The most frequently developed themes in these sessions are death anxiety, fear of recurrence, facing diagnosis day news, chemotherapy, radiotherapy and hormone treatment side effects, body and self image, sexuality, relationships with partner, family and friends, surgical reconstruction and life style effects. Technical aspects of the therapy are described and group member's opinions and difficulties of this approach are discussed.

4. Pablo Orgaz Barnier, Dr., pablo_orgaz@yahoo.es
5. Jose Enrique Benitez, Mr, joseenrique.benitez@uam.es

Introduction: Pain is a complex experience, which includes cognitive, affective and behavioural aspects. The interrelation between depression and pain experience is bidirectional, many data support the idea that a depressive affect boosts the experience of pain.

Objectives: Identify concrete emotional aspects on the experience of pain which could receive a psychological or pharmacological antidepressant treatment.

Method: Qualitative analysis of focal discussion groups of patients with chronic pain. Groups of over ten patients are aimed to talk about their pain experience and it’s affective implications. Every patient is under treatment for their pain (and affective disorder if needed). What groups say is transcribed and analyzed by a team of researchers (psychiatrists and psychologists). Atlas-Ti software is used to assist the analysis of the transcriptions, all the process is based on grounded theory methodology.

Results: An evolution of the personal narrative of patients about their pain is observed. Psychotherapy and antidepressants seem to promote changes on the way that patients experience pain and in some effects.

5. Carmen Bayón Pérez¹, Dr, PhD, cbayonp@gmail.com
6. Alberto Fernández Liria², Dr, PhD, afliria@gmail.com

Introduction: The prevalence of depression in oncologic patients is four times higher than in general population. Depression affects a 30% of the patients during the course of their disease. Treatment of psychiatric symptoms is strongly recommended to improve cancer therapy evolution, being combined treatments (psychological plus pharmacological) the most effective and less relapse producing. Qualitative analysis of focal groups provide an important amount of data which complement the diagnostic process and it results to be a complement on assessing quality of life. This study is part of the FIS 07/90348 and 07/90452 Investigation Projects.

Objectives: Obtain main dimensions of patients subjective experience of oncologic disease and its treatment.

Method: Qualitative analysis of focal discussion groups. Sample: 25 depressed subjects with a breast, lung or colon tumour, in I or II stage, without metastases or relapse. All of treated for their depression. One group received a combined treatment while the other received a pharmacologic one. Experience of illness and treatment was analyzed by a group of researchers. Atlas-Ti software was used in the analysis of the transcriptions. The speech was reduced to its meaning units, and then analyzed following grounded theory methodology (grouping and relating quotes).

Results: Three different main categories emerged from our groups of patients. Suffering experience, meanings and support elements.

NEED OF PSYCHIATRIC HELP IN A SAMPLE OF NON METASTATIC CANCER PATIENTS

INSTITUTIONS
1. Hospital la Paz, Psiquiatría, Madrid, Spain
2. Hospital Príncipe de Asturias, Psiquiatría, Alcalá de Henares, Madrid, Spain

AUTHORS
1. Beatriz Rodríguez-Vega¹, Dr, MD, beatrizrvega@gmail.com
2. Carmen Bayón-Pérez², Dr, MD
3. Angela Palao-Tarrero³, Dr, MD
4. Guadalupe Torres-Sancho⁴, Mrs
5. Guillermo Benito-Ruiz⁴, Mr.
6. María Dieguez-Porres⁵, Dr., MD
7. Ana Hospital⁶, Mrs

AIM: Analyze the perception of psychologic or psychiatric need of help on a sample of three of the most prevalent kinds of tumours (breast, lung and colon).

METHOD: 768 patients of breast, lung or colon cancer without metastasis who were under treatment at La Paz and Príncipe de Asturias Hospitals in Madrid. Participants were asked to complete a survey designed for the study, which included the HADS (Hospital Anxiety and Depression Scale). Subjects who scored 8 or higher were interviewed to confirm the diagnosis of major depressive disorder. All participants were asked about their need of psychiatric or psychologic help.

RESULTS: people who thought that needed help but scored less than 8 in the scale, was much higher than the number of patients depressed on any of the tumour groups (N= 251). Both anxiety and depression scores were under 8 on those patients, excluding other causes for the need of help.

CONCLUSIONS: we think that this data means that what patients ask is not a formal therapeutic treatment (which is a need in case of depression or anxiety). Their need is more of an emotional which helps to treat that subclinical symptoms and also the suffering. The psychococial implications of cancer and the increase of the populations’ expectatives of take care of their emotional needs during the treatment. Qualitative research oriented to patients’ subjective experience, would make this point clearer.

This study is part of a research line funded by the FIS (Health Research Fund). Project numbers P1005737, P1052062.

DULOXETINE FOR PREMENSTRUAL DYSPHORIC DISORDER: A PILOT STUDY

INSTITUTIONS
1. IPSEMG - Instituto de Previdencia dos Servidores do Estado de Minas Gerais, Psychiatry, Belo Horizonte, Brazil

AUTHORS
1. Melissa G Ramos1, Dr., MD, melissaguarieiro@hotmail.com
2. Cláudia Haral1, Dr., MD, harala@uol.com.br
3. Fábio L Rocha1, Dr., MD, PhD, rochafl@uol.com.br

Introduction: Premenstrual dysphoric disorder (PMDD) affects 3% to 8% of women of reproductive age and is characterized by severe mood symptoms that cause important functional impairment. Serotoninergic antidepressants appear to be an effective treatment for this disorder. The purpose of this study was to investigate the efficacy and tolerability of duloxetine, a reuptake inhibitor of serotonin and norepinephrine, in the treatment of PMDD.

Methods: We conducted a pilot, single-blind, non-controlled, fixed-dose trial. After two menstrual cycles for diagnostic confirmation, including a single-blind placebo cycle, 20 women who met DSM-IV-TR criteria for PMDD were included in the treatment phase. Daily doses of 60 mg of duloxetine were administered during 3 menstrual cycles.

Results: The primary measure of the efficacy of treatment with duloxetine was the significant reduction in premenstrual symptoms demonstrated by the comparison between mean scores in the Daily Record of Severity of Problems (DRSP) at baseline and endpoint (p=0.0002). Statistically significant symptom reduction was observed throughout all treatment cycles. Clinical response, defined as a reduction ≥ 50% in baseline premenstrual symptoms, occurred in 65% of subjects (intent-to-treat population). Significant improvements were demonstrated by secondary measures, including reduction in self-rated functional impairment (p=0.01) and improvement in quality of life (p=0.04). Main side effects were dry mouth, nausea, drowsiness, insomnia, decreased appetite, decreased libido, and sweating.

Conclusions: Duloxetine was effective and well tolerated in the treatment of PMDD. Further large-scale, double-blind, placebo-controlled studies are needed to evaluate duloxetine as an additional treatment strategy for the management of PMDD.

OBJECTIVE: This paper aims to evaluate the anti-emetic efficacy of the cannabinoids in cancer patients receiving chemotherapy.

METHODS: Systematic Review of Literature. Electronic Databases: PUBMED, EMBASE, PSYCINFO, LILACS, “The Cochrane Collaboration Controlled Trials Register”. Studies chosen were randomized clinical trials comprising all publications of each database until December 2006.

RESULTS: From 12,749 initially identified papers, 30 fullfield the inclusion criteria for this review, with demonstration of superiority of the antiemetic efficacy of the cannabinoids compared to the conventional drugs and placebo. The adverse effects were more intense and occurred more often among patients who used cannabinoids. Five metanalysis were carried out: 1- Dronabinol versus Placebo (N = 325; RR = 0.67; CI = 0.47 - 0.96; NNT = 3.4); 2- Dronabinol versus Neuroleptics (N = 277; RR = 0.88; CI = 0.72 - 1.08); 4- Levonantradol versus Neuroleptics (N = 194; RR = 0.94; CI = 0.75 - 1.18); 5- patients preference for cannabis or other drugs (N = 1138; RR = 0.33; CI = 0.24 - 0.44; NNT = 1.8).

CONCLUSIONS: The superiority of the anti-emetic efficacy of cannabinoids was demonstrated through meta-analysis.

Objective: To evaluate the analysis of patients creative production is useful in diagnosis and, moreover, can be used in psychotherapy.

Methods: We asked our patient, a forty-five year old woman who diagnosed with paranoid schizophrenia, for some photographs of her best pictures. We also asked her to tell us what she wanted to transmit by them. We compared her painting to the psychopathological exploratory resulting from the clinical interviews which were planned by the team of Mental Health in Macarena Centro District for the last eighteen months.

Results: Throughout our patient’s different pictures, the different Clinical phases of schizophrenia and the progress in her Disease can be seen.

Conclusion: Schizophrenic art holds some own features. Throughout colours, strokes or topic we can approach to patient feelings and can be useful in diagnosis and can be used in psychotherapy.

PSYCHIATRIC REVOLUTIONS: A HISTORY OF PSYCHIATRY

INSTITUTIONS
1. Harvard, Psychiatry, Cambridge MA, United States

AUTHORS
1. Albert Rothenberg1, DR., MD, albert_rothenberg@hms.harvard.edu

Aims: “They who do not know history are destined to repeat it.” The important point of the aphorism is not just advocacy of learning to avoid the mistakes of history but the building up of knowledge about beneficial trends and dynamisms in order to continue and improve them.

Methods: Assessment of the history of psychiatry reveals that modern practice and theory has developed from a series of radical and generative changes or revolutions.

Results: The five psychiatric revolutions are as follows: Moral Therapeutic: striking of chains from the mentally ill, beginning of the psychotherapeutic: Pinel, Esquirol, Charcot, Janet; Paradigmatic: theories and practice of Freud, Jung, Adler, Rank, Klein and followers; Biomolecular: Discovery and introduction of prototypic drugs (and precursors); chlorpromazine (reserpine); lithium carbonate (lithium urate); imipramine (isoniazid); chlordiazepoxide (meprobamate); Behavioral: Diagnosis, long the gold standard of European psychiatry, and the revolutionary and international impact of the introduction of DSM III and its successors on the current status of psychiatric nosology; Social: Therapeutic community, development of mental health centers, deinstitutionalisation, provider diffusion, impact of third part payment (nationalization, managed care).

Conclusions: Understanding these changes, their impact, and the resulting current consolidation, will help guide future creative developments in practice, teaching, and research.

Aims: The experience of posttraumatic growth following breast cancer, its association with psychological distress and the predictive value of psychological distress, sociodemographic and clinical characteristics of cancer patients in their personal growth.

Methods: 111 patients with advanced breast cancer (stage IV) attended the outpatient oncology unit of Helena Venizelos Hospital (Ι=70) and the palliative care unit of the Aretion Hospital (Ι=41) in Athens. The final sample consisted of 100 consecutive patients suffering from incurable cancer. Posttraumatic Growth Inventory (PTGI) was used in order to investigate posttraumatic growth among Greek advanced cancer patients. PTGI consists of 21 items which are included in 5 factors: FI= "Relating to others", FII= "New possibilities", FIII= "Personal strength", FIV= "Spiritual change", FV= "Appreciation of life". Patients also completed the Greek version of the Hospital Anxiety and Depression Scale (HADS), a measure specifically designed for use with general medical and surgical patients, which is particularly appropriate for cancer patients. Sociodemographic and clinical characteristics were recorded.

Results: The analysis showed that significant associations were found between PTGI ‘Total patients’ age (p=0.001), and being married (p=0.007). Moreover, significant negative association was observed between PTGI-II ("new possibilities") and HADS-Depression (r = -0.314, p<0.05). Multiple regression analyses showed that "age" is a significant predictor of PTGI-II ("new possibilities") (p=0.005), PTGI-V ("appreciation of life") (p=0.0005) and PTGI-Total (p=0.037), while marital status is a significant predictor of PTGI-Total (p=0.009).

Conclusion: Specific patients’ characteristics, like young age, and being with a partner, influence the experience of posttraumatic growth in breast cancer patients.

QUALITY OF LIFE AND POSTTRAUMATIC GROWTH WITHIN WAR TORTURE SURVIVORS IN POSTTRAUMATIC SOCIETY

INSTITUTIONS
1. Clinical University Center, Psychiatric Clinic, Sarajevo, Bosnia and Herzegovina

AUTHORS
1. Dubravka Salcic1, Mrs, PhD MD, dubsd@bih.net.ba
2. Senadin Fadilpasic1, Mr, cvmost1@bih.net.ba
3. Alma Bravo Mehmedbasic1, Mrs, PhD MD, cvmost1@bih.net.ba
4. Abdulah Kucukalic1, Mr, PhD MD, cvmost1@bih.net.ba

Aim: Aim of this article is to assess quality of life and the level of posttraumatic growth within torture survivors in posttraumatic society.

Method: Research sample consisted of 128 clients from Canton Sarajevo and town Stolac. All clients experienced war torture and were included in multidisciplinary treatment within Center for torture victims during 2007. Clients were tested at the beginning of treatment and retested one year after. As research instruments Sociodemographic questionnaire (CTV Sarajevo, 2006), Manchester Quality of Life Scale and Posttraumatic Growth Inventory (Tedeschi and Calhoun) were used.

Results: The retest results of this study shows that quality of life as well as the level of PTG after one year of treatment was improved in Canton Sarajevo, while in town Stolac quality of life did not differ significantly. Similarly at the end of treatment results on posttraumatic growth did not differ significantly in Stolac. Results of research shows in both regions statistically significant correlation between results obtained on Quality of life scale and PTGI.

Conclusion: This results indicate that complex conditions of continuous political tensions, divided health care and education system and community as a whole, very bad general life and economic situation in town Stolac impacted quality of life and posttraumatic growth, while more stable political and economic situation in Sarajevo Canton results with better quality of life and posttraumatic growth within war torture survivors.

PSYCHOPATHOLOGICAL FEATURES OF INMATES WITH SUBSTANCE ABUSE AND ADDICTION IN AN ITALIAN PRISON POPULATION

INSTITUTIONS
1. University of Molise, Department of Health Sciences, Campobasso, Italy
2. D’Annunzio University, Faculty of Psychology, Chieti, Italy

AUTHORS
1. Chiara Cuomo¹, nthstar@gmail.com
2. Francesco Basilico¹
3. Miriam Iosue²
4. Deborah Cancellario²
5. Massimo Di Giannantonio³
6. Marco Sarchiapone¹

Aims: Substance abuse and addiction has been a serious concern among the prison population worldwide. Specific management of prisoners with substance-related disorders could be required in order to reduce the additional burden in terms of health, economic and human resources employed in prisons for these inmates. A psychological profile of inmates with substance abuse can be helpful in developing directions and guidelines specifically addressed to the management of prisoners with such problems; aim of our study is then to analyse psychological and judicial features of a subgroup of inmates with substance abuse in a sample of Italian prisoners.

Methods: Substance abusers (N=312) were compared to a sample of inmates without substance abuse (N=591). Prisoners recruited completed a semi structured interview for collection of sociodemographic and judicial data and a battery of psychometric tests for assessment of aggression, impulsivity, depression, personality traits, hostility, resilience and childhood trauma.

Results: Substance abusers had on average multiple incarcerations, more juvenile convictions, more violent behaviours during detention and a history of one or more suicide attempts. They also had higher scores on subscales for childhood trauma, higher scores for psychoticism and neuroticism, higher impulsivity levels, worse resilience, increased hostility and prevalent suicidal ideation.

Conclusion: Substance abuser inmates constitute a subgroup with increased judiciary and psychiatric issues, possibly due to early life history and psychological characteristics, such as high impulsivity and aggressiveness, poor resilience, and higher suicidal risk.

THE ORIGIN OF “BRAZILIAN LEAGUE OF MENTAL HYGIENE” AND ITS HISTORICAL CONTEXT

INSTITUTIONS
1. Psychiatry Institute - University of São Paulo Medical School, Protoc - Programa dos Transtornos do Espectro Obsessivo Compulsivo, São Paulo, Brazil

AUTHORS
1. André A Seixas¹, Mr., MD, aaaseixas@protoc.com.br

Background: In the earliest decades of the twenty century, took place, in Brazil, a movement to reform its Mental Health system. The cultural and politics context are important to understand the Brazilian Psychiatry concepts of that time.

Objective: To report the beginning of “Brazilian League of Mental Hygiene” and its degeneration idea.

Methods: Historical. Bibliography research of primary source and official documents.

Result: Were analyzed originals texts of Archives of Brazilian Mental Hygiene (“Arquivos Brasileiros de Higiene Mental”) between 1928 and 1934. Those texts reinforce the degeneration concept present at “Brazilian League of Mental Hygiene”, its consequence on psychiatry practice and its influence to organized the Brazilian politics on Mental Health at that time.

Conclusion: The “Brazilian League of Mental Hygiene” was based in anti-liberal ideas and degeneration concept.

Background and Aim: Depression is the world's fourth most prevalent health problem which is associated with substantial mortality, direct medical cost and diminished quality of life. According to the WHO report by the year 2020, depression will constitute the major health problem in the developing world and the second biggest cause of disease burden worldwide. The aim of this study was to investigate the effects of group psychotherapy on life quality of a sample of Iranian patients with major depressive disorder

Methods: 70 patients who were willing and had met the required criteria for participation were selected and assigned into two groups of experimental and control group. For data collection a two part questionnaire was developed, the first part consists of 13 items related to general characteristics and the second part with 36 items on life quality were used. The experimental group was divided into 5 subgroups of 7 patients. For each group 6 intervention sessions were scheduled. The control group didn't receive the intervention. The questionnaire was completed by researcher for all subjects in the experimental and control groups before the group psychotherapy and one month after the end of group psychotherapy.

Results: The result of the study indicated that group psychotherapy in comparison with other available treatments proved to be more effective on 8 domains of life quality in the experimental group. A significant difference was observed for all the domains.

Conclusion: Group psychotherapy has effect on life quality of patients with major depressive disorder.

PSYCHOSOCIAL AND ENVIRONMENTAL FACTORS AT PATIENTS MAINTAINING SECURITY MEASURES

INSTITUTIONS
1. Special Psychiatric Hospital, Center of Forensic Psychiatry, Nis, Serbia and Montenegro
2. Military Hospital, Neuropsychiatric Ward, Nis, Serbia and Montenegro

AUTHORS
1. Sanja M Stanojkovic, Dr, MD, mils@medianis.net
2. Snezana S Vladejic, Dr., MD, mils@medianis.net
3. Milan D Stanojkovic, Dr, MD, mils@medianis.net
4. Sibin D Vladejic, Dr, MD, vladec@bankerinter.net

Center of Forensic Psychiatry of Special Psychiatric Hospital, Gornja Toponica, is conducting security measures, which are pronounced towards patients, which committed criminal acts. They were found insane at the time of criminal act and therefore "not guilty by the reason of mental disability". They were diagnosed with different diagnostic categories, psychotic and non-psychotic. During period of January 2003 - December 2005 we conducted research at Center, tending to establish the influence that psychosocial and environmental factors have in criminogene activity of our patients, but also in the matter of their release from the hospital and social reintegration. To verify the presence of these factors, we used Axis IV of Diagnostic and Statistic Manual of Mental Disorders IV Revision, (abbr. DSM-IV) (American Psychiatric Association, 1994) according to Structured Clinical Interview for DSM IV Axis I Disorders, Clinical Version (abbr. SCID I CV); Structured Clinical Interview for DSM IV Axis II Personality Disorders (abbr. SCID II). The research included 237 patients that were treated during this period at the Center. The significant presence and influence of psychosocial and environmental factors was found at the patient of all diagnostic categories; also, they had significant influence on rehospitalization, exacerbations and relapses at our patients. There was statistically significant difference between present social and environmental factors in group of psychotic and non-psychotic patients. Psychotic patients are exposed to poverty and unemployment at significantly higher rate.

COMPUTER-ADMINISTERED COGNITIVE BEHAVIOURAL SELF-HELP: IS IT ACCEPTABLE AND HELPFUL FOR ADOLESCENTS WITH MILD TO MODERATE DEPRESSIVE SYMPTOMS?

INSTITUTIONS
1. University of Auckland, Department of Psychological Medicine, Auckland, New Zealand

AUTHORS
1. Karolina Stasiak¹, Ms, k.stasiak@auckland.ac.nz
2. Sally N Merry¹, Dr, MD, s.merry@auckland.ac.nz
3. Simon Hatcher¹, Dr, PhD, s.hatcher@auckland.ac.nz

Aims: The aim was to design and evaluate the feasibility, efficacy and acceptability of self-help computerised CBT (CCBT) for adolescents with mild to moderate depressive symptoms.

Methods: The programme was trialled in a small RCT with 34 adolescents assigned to CCBT or a matching computerised psychoeducation (CPE) condition. Qualitative and quantitative user feedback was also collected.

Results: 94% of CCBT and 82% of CPE participants completed the intervention. Controlling for age and gender, repeated measures ANOVA showed a significant decrease on CDRS-R for the older (16-18 year old) adolescents compared with the CPE condition (F(2,24)=13.89, p<0.000). The RADS-2 scores were also significantly improved for older CCBT adolescents (F(2,24)=4.83, p<0.017) compared with their CPE counterparts. Significant improvements in CDRS-R (F(2,36)=23.91, p<0.000) and RADS-2 (F(2,36)=6.22, p=0.001) were observed in the younger (13-15 year old) adolescents irrespective of group allocation. CDRS-R scores improved more for males than for females regardless of group allocation (F(2,56)=6.30, p=0.003). Participants deemed CCBT and CPE to be equally useful, easy to use and engaging. Feedback suggested that CCBT taught some adolescents cognitive restructuring and problem solving while anger management and stress reduction techniques were identified as the most useful CPE topics. The participating adolescents wanted future programmes to maximise the use of multimedia/interactive gaming features and the topics to include recovery stories from credible role models.

Conclusions: It is reasonable to assume that computerisation of self-help interventions will continue to grow and progress in this field should include work on developmentally appropriate solutions for adolescent-specific treatments.

PSYCHOTHERAPY OF ART IN CHILDREN AND ADOLESCENT PSYCHIATRY

INSTITUTIONS
1. Motol University Hospital, Child Psychiatry, Prague, Czech Republic

AUTHORS
1. Marina Stejskalova¹, Dr., PhDr., CSc., stejskalova.marina@volny.cz

This workshop presents a modern method of treatment for children and adolescent patients by means of the psychotherapy of art. The psychotherapy of art is a process of influencing people by art, physiological, emotional, sensational and behavioral. Psychotherapy of art is very significant in clinical practice. Extraordinary part of psychotherapy of art is clinical diagnostics and the structure of patient’s personality. The classification of psychotherapy of art shows its different types: artetherapy, dancetherapy, ergotherapy, bibliotherapy, musictherapy, movietherapy, therapy of photography, dramatherapy. This workshop also shows different forms of musictherapy (group and individual, receptive and active, soundtherapy, singing and working with a voice, musictherapy videoprograms). It is important to note that different kinds of psychotherapy of art are useful for different diagnostics. For example the ergotherapy is very helpful for patients with psychotic diseases. It helps them return to reality. The dancetherapy is suitable for a broad range of diagnostics. Bibliotherapy is effective at work with elective mutism, children with learning and attention disorders, behavioral disturbances, eating disorders, post-traumatic stress disorders, with battered, unkept and sexually abused children, psychotic diseases. The important part of the psychotherapy of art is creating treatment programs according to clinical diagnostics. The workshop informs participants about some these programs dealing with the treatment of children with eating disorders, children with ADHD, depressions, anxiety disorders, adolescents after TS and also patients with psychotic diseases. The workshop has a cognitive and experience character.

WOMEN INTERGERATIONAL PRACTICES IN THREE GENERATIONS FAMILIES

INSTITUTIONS
1. Pontifícia Universidade Católica do RGS, Graduated Program, Porto Alegre, Brazil

AUTHORS
1. Marlene N. Strey, Doctor, PhD, streymn@pucrs.br
2. Beatriz Ojeda, Doctor, PhD
3. Marísa Vieira, Doctor, PhD
4. Heloísa Bello, Doctor, PhD
5. Gilda Pulcherio, Mrs., MD

Objective: The aim of this study is to understand the female subjectivity construction through generations, time, and space in the perspective of women participants.

Method: This is a qualitative study with three women generations of five families from different geographic localization in the South of Brazil through narrative interviews, and using discourse analysis to discuss the data.

Results: The data revealed that generations are quite different from another depending of home structure, cultural environments and networks, the emotional atmosphere in the family. Nevertheless they display some similarities due to historical practices in the family or cultural environments.

Conclusions: Family bonds are complex issues, and must be studied by multiple approaches to be better understand.

COMBINES LOW DOSE TIANEPTINE AND ELECTRO-ACUPUNCTURE ACCORDING TO DR. VOLL FOR TREATMENT OF MAJOR DEPRESSIVE DISORDER IN BREAST CANCER PATIENTS

INSTITUTIONS
1. Odessa State Medical University, Department of Psychiatry, Odessa, Ukraine

AUTHORS
1. Vyacheslav V. Sushko, Dr., PhD, sushkodoctor1@renome-i.net

Background: The side effects of psychotropic remedies significantly impair in breast cancer patients. Electro-acupuncture according to Dr. Voll based on correction of body's functions under influence of electromagnetic oscillations of strictly determined parameters, similarly to tuning-fork replying to certain frequency spectrum of acoustic wave.

Aims: The aim of this study was to test the efficacy combines low dose tianeptine and electro-acupuncture according to Dr. Voll in treatment of major depressive disorder in breast cancer patients.

Methods: Sixty-one breast cancer patients after mastectomy with major depressive disorder were randomly assigned to experimental or control groups in Odessa Regional Cancer Hospital. The thirty patients of control group received tianeptine in a dose of 0.0375 g/day during eight-week period. The thirty-one patients of experimental group participated in an eight-week program that combines tianeptine in a dose of 0.025 g/day and electro-acupuncture according to Dr. Voll. Each patient was assessed at the follow-up interview took place at two months after baseline via a psychiatric interview and standardized psychological tests Hospital Anxiety and Depression Scale (HADS) with the added breast cancer specific module.

Results: After two months of treatment, 93.5% patients from the experimental group and 73.3% from the control group showed significant clinical improvement, total symptom score of the Hospital Anxiety and Depression Scale was likewise significantly reduced ($F=5.3$, $p<0.01$).

Conclusion: For breast cancer patients with major depressive disorder who cannot take high doses of antidepressant medication, combines low dose tianeptine and electro-acupuncture according to Dr. Voll is useful.

ASSESSMENT OF POSTGRADUATE EDUCATIONAL ROTATION SYSTEM IN WAKAYAMA MEDICAL UNIVERSITY HOSPITAL - FROM THE VIEWPOINT OF THE RESIDENTS

INSTITUTIONS
1. Wakayama Medical University, Department of Neuropsychiatry, Wakayama City, Japan
2. Wakayama Medical University Hospital, Postgraduate training center, Wakayama City, Japan

AUTHORS
1. Shun Takahashi1,2, Dr, MD, t-shun@wakayama-med.ac.jp
2. Tomikimi Tuji1, Dr, MD, PhD
3. Satoshi Uki1, Dr, MD, PhD
4. Masahiro Yamamoto1, Dr, MD
5. Asami Kose1, Dr, MD
6. Masaru Shoyama1, Dr, MD
7. Eiko Ueyama1, Dr, MD
8. Masami Ueno2, Dr, MD, PhD
9. Kazuhiro Shinosaki2, Dr, MD, PhD

Background:
In Japan, a new postgraduate educational rotation system has started in 2004. Junior residents are required to do training in the various areas in their 2-year internship period including one-month psychiatric training. Then, they become senior residents for their individual intended specialty. Some reports have shown that not all the junior residents have been satisfied with the psychiatric training. The aim of this study is to assess the present psychiatric training program in Wakayama Medical University Hospital from the residents’ viewpoint.

Methods:
We carried out a questionnaire survey for the junior (n=36) and senior (n=44) residents, and the psychiatric clinician-teachers (n=7). The questionnaire includes 1) several questions about the fifteen psychiatric training items, 2) a question about the reputation of the training, and 3) a question about its motivation. We examined 1) which item is important from the standpoint of the residents and the clinician-teachers, 2) which item has not been trained enough by the residents, and 3) which item is useful for the non-psychiatric clinicians.

Results/Discussions:
Between residents and clinician-teachers, there is no difference in distribution of weighting on the fifteen training items. The residents considered that they have not taken enough clinical training about delirium, hypnotics, EEGs, mental disorders due to general medical conditions, and assessment of psychotic states. The senior residents considered that clinical training of delirium, hypnotics, and dementia is useful for the non-psychiatric clinicians. Reputation of the psychiatric training affects residents’ motivation, suggesting that improvement in the psychiatric training program encourage residents’ motivation.

4. Agata Orzechowska1, Mrs, psychologist
5. Piotr Galecki1, Mr, MD PhD

Aims: According to salutogenesis approach, the health and the disease are a continuum on which we try to establish the position of man [1]. Authors would like to check if the level of SOC (sense of coherence) and strategies of coping with stress are connected with depression and dermatological diseases.

Methods: The examined group contained of 167 patients (69 suffered from depression and 98 patients diagnosed with the acne rosacea). Antonovsky’s Sense of Coherence Scale (SOC-29) and the Moos Coping Test were used.

Results: The level of global sense of coherence (SOC) and the level of each subscales was higher among dermatological patients. The difference is statistically relevant. The values of test T are also relevant in case of each subscales. In case of the Moos Coping Test the statistically relevant differences were obtained in two scales: seeking information and support and taking problem-solving action. These mean values were higher also among patients suffering from the acne rosacea.

Conclusions: 1) Sense of coherence is relevantly higher among men suffering from depression as well as from acne rosacea. 2) SOC level remains in relevant dependency with the intensity of depressive disorders and with the strategies of solving problems. 3) The strategies of coping with stress essentially differentiate examined patients depending on the level of SOC.

Women with anxiety and depression during pregnancy are at increased risk for postnatal depression which is a serious condition affecting the cognitive and emotional development in the infant. Antenatal psychiatric disorders are also associated with obstetric complications and reduced foetal and neonatal well-being. Risk factors for anxiety and depression in undeveloped countries are to some degree culturally based. Aim: To study risk factors for antenatal anxiety and depression in women in Tanzania

Method: Women coming to a hospital for delivery were assessed on anxiety and depression on Hospital Anxiety and Depression scale(HADS), in addition to a range of somatic and psychosocial factors, including culturally based risk factors as illiteracy and polygami.

Results: The prevalence of anxiety disorders was about 25% and the prevalence for depression about 10%. More extensive results will be presented.

Conclusion: Antenatal anxiety and depression is highly prevalent in women in Tanzania coming for delivery at a hospital. The role of different risk factors will be discussed.

15. Tetsuro Ohmori1

Aims/Objectives: The aim of the present study is to investigate the relation between subjective quality of life and cognitive function in people with schizophrenia.

Methods: Subjects were forty-six stabilized outpatients with schizophrenia (DSM-IV). Their mean age was 39.8 (SD=11.6) years. Subjective quality of life and cognitive function were assessed using the Schizophrenia Quality of Life Scale (SQLS) and the Brief Assessment of Cognition in Schizophrenia (BACS), respectively. Clinical symptoms were assessed with the Positive and Negative Syndrome Scale (PANSS), the Calgary Depression Scale for Schizophrenia (CDSS), and the Drug-Induced Extrapyramidal Symptoms Scale. All subjects signed a written informed consent form approved by the Ethics Committee of University of Tokushima. Subjects were excluded if they presented with any organic central nervous system disorder, epilepsy, mental retardation, and severe somatic disorder.

Results: The SQLS scores significantly correlated with the CDSS score. Psychosocial scale and motivation and energy scale of the SQLS significantly correlated with positive syndrome scale of the PANSS. However, the SQLS scores did not correlate with the BACS measures. Stepwise regression analyses showed that the CDSS score was the most important predictor of the SQLS.

Conclusion: These results show that subjective quality of life is not related to cognitive function but is associated with depressive symptom in people with schizophrenia. We conclude that treatment for depressive symptoms might be important in order to improve their subjective quality of life.

ASPECTS OF INCAPACITY IN THE ELDERLY

INSTITUTIONS
1. UHSTNP "Sv. NAUM", Clinic of forensic psychiatry and forensic psychology, Sofia, Bulgaria

AUTHORS
1. Denitsa M. Topouzova1, Mrs., MD, deniza_topouzova@yahoo.com

Legal term "incapacity" is formulated in Bulgarian Person’s and Families’ Act. Natural continuum capacity-incapacity is divided onto three stages from the law: global capacity, limited/not diminished/ capacity and incapacity. Medical criteria for capacity are lack of mental illness or weakness of mind, wherefore a person “couldn't carry out own things”. Capacity of a person, “whose state is not so severe” could be limited by the court. Other formulations of specific for the elderly competencies are included in Liabilities and Contracts Act and Legacy Act. In these acts is required the person should be able to understand and to lead his/her actions, without fixing any medical conditions. There is lack of legal definition of temporary states of incapacity. Partial loss of competencies, often observed in the elderly, is also not reflected by the law. Perhaps one exception, which represents temporary and partial incapacity, is incompetence to give informed consent to treatment /Health Act, 2004/. Described legal conditions and international variety of “incapacity” formulations complicate systematic research in the “emerging area” of psychiatric assessment in the elderly.

DISTRIBUTION OF CRIMINAL ACTIVITY AMONG MENTALLY ABNORMAL OFFENDERS

INSTITUTIONS
1. Medical faculty Nis, psychiatry, Nis, Serbia and Montenegro
2. Psychiatry Hospital Gornja Toponica, Gornja Toponica, Serbia and Montenegro

AUTHORS
1. Suzana M Tasic Golubovic1, Dr, PhD, gnebojsa@bankerinter.net
2. Sanja Stanovkovic2, Dr, MD
3. Snezana Vladejic2, Dr, MD

Objective: Crime may be simply defined as the breaking of the criminal law. Irrespective of which line of investigation in literature there was convincing evidence that violent/homicidal behavior was associated significantly with mental illness. The purpose of this study was assessing the distribution of criminal activity, as well as, various types of criminal behavior, among mentally abnormal offenders treated in maximum-security setting - Forensic Center in Gornja Toponica in a period from 2000. to 2007.

Method: Diagnostic ICD X criterions for mental disorders, clinical interview and the psychiatrist's reports in the authority courts were used in the retrospective evaluation.

Results: The most frequent diagnosis was schizophrenia, especially paranoid type, and the most frequent type of offence was homicide and attempted murder, while among patients suffering from anti-social personal disorder physical injury and rape were the most frequent offences. Obtained results are statistically significant. Schizophrenia may be associated with violent crime, and certainly such acts that may lead to considerable publicity and attract a great deal of attention because of dramatic clinical state of schizophrenia, impulsive behavior, often associated with bizarre crime, monstrous homicides and other offences because of a decline in social functioning competence. These facts may explain the most frequency of schizophrenic patients among the investigated ones.

Conclusions: Mental abnormality and offence are significant socio-pathological phenomena. Although mental disorders per se are significantly associated with violence/homicide behaviors, it is reasonable to believe that targeting certain subgroups of patients should be helpful. Probably the presence of psychotic symptoms is a significant risk factor in violence/homicide behaviors in mentally ill.

LITERATURE AND PSYCHIATRY INTERROGATING EMPATHY

INSTITUTIONS
1. George Washington University, Psychiatry and Behavioral Sciences, Washington, DC, United States

AUTHORS
1. Antolin Trinidad1, Dr., MD, atrinidad@mfa.gwu.edu
2. Linda Raphael1, Prof., PhD, msdlrs@gwumc.edu

Medical education has recently adopted a strident insistence on the teaching of empathy, thought to have crucial therapeutic benefits on the doctor patient relationship across many specialties. We will talk about our experience in running a medical humanities program in a medical school. In addition, we will discuss how psychiatry in particular elevates empathy to among its strongest therapeutic advantage and takes pride in its supposed special understanding and skilled use of it. We will then interrogate the idea that empathy is static and that once acquired, it is always present. After this, we will examine the alternative concept that empathy is fluid and that psychiatrists, faced with dynamic and varying clinical situations, need to rediscover empathy in each situation. We will argue that one potentially effective way to do this is a lifelong engagement in creative literature. In this symposium, we will study narrative competence and how close textual engagement in the reading of literature parallels the close reading of lived human experience as told by patients. In essays written by patients for instance, psychiatrists and other therapists could capture the emergence and creation of unique meanings during the composition of a narrative - this kind of discovery is not always possible without attention to the precepts of literature as a discipline. Examples of literary texts will be discussed such as passages from Virginia Woolf’s Mrs. Dalloway, Franz Kafka’s Metamorphosis, Emily Dickinson’s poetry and Joan Didion’s memoir on the death of her husband.

WHY THE HUMANITIES ESPECIALLY LITERATURE ARE MEDICAL/PSYCHIATRIC DISCIPLINES

INSTITUTIONS
1. The George Washington University, Washington, DC, United States

AUTHORS
1. Antolin Trinidad

I will argue that the humanities especially literature is a legitimate medical discipline. Literature remains especially relevant to psychiatry. The production, analysis and continual interrogation of narratives - how people tell stories and what they tell - are core processes in all of medicine. The practice of psychiatry is unfathomable without narratives. Creative literature is a form of a continuing intellectual engagement with the varieties of narratives; they expand the human experience and imagine alternatives to the painful realities of human life. Creative literature have the same characteristics as that type that can be healing for our patients. It partially offsets the risk of theory-bound insularity in psychotherapy. In this presentation, I will use examples from the works of Franz Kafka, Virginia Woolf and Stephen King that illuminate the dynamic tension between distress, narrative-production and healing. Finally, I will recommend practical uses of literature in working with patients in psychotherapy.

IMAGINING EMPATHY: ANATOLE BROYARD’S “THE PATIENT EXAMINES THE DOCTOR” AND HENRY JAMES’S “THE MIDDLE YEARS”

INSTITUTIONS
1. George Washington University, Psychiatry and Behavioral Sciences, Washington, DC, United States

AUTHORS
1. Linda Raphael1, Prof., PhD, msdlsr@gwumc.edu

We initiated a program in Medical Humanities at GWU School of Medicine in 2005/2006. Our emphasis on literature and medicine, or narrative medicine, is intended to teach students and physicians to read texts closely in order to better understand patients’ stories and their own narratives as well. Such understandings, we believe, foster the development of empathy (an often misunderstood term that I will attempt to define in the presentation). One text I use in the primary care clerkship, literature and medicine electives for first and second-year students, and the medicine residency has been highly controversial: Anatole Broyard’s essay “The Patient Examines the Doctor.” In each group I focus on different parts of this very literary narrative that offers multiple possibilities for considering doctor/patient relationships. Not only does each group concentrate on aspects of the essay most relevant to their experience, but their reception of Broyard’s robust demands on the doctor is greatly affected, I argue, by their stage in medical education. In this presentation, I will discuss my experiences in teaching this essay, with a consideration of how we might understand Broyard’s desires in terms that Henry James develops in “The Middle Years,” a story that illuminates what empathy might “look like” to patients and to doctors.

3. Athanasios Xiromeritis1, Dr, MD
4. Odysseas Mouzas1,2, Dr, PhD
5. Nikiforos Angelopoulos1,2, Dr, PhD

Background/Aim: People with psychotic and mood disorders are in great risk of weight gain and obesity because of inactive, unhealthy lifestyles and use of psychotropic medication.¹ The aim of this case study was to assess the effectiveness of a psychoeducational intervention on psychotropic-induced weight gain in two patients.

Design and Method: Single subject quasi-experimental design: Two female out-patients, who had both gained weight (BMI>25), after they had been introduced to olanzapine and fluoxetine treatment respectively, attended a weekly treatment package that comprised of: (a) psychoeducation, focused on nutrition, exercise and healthy lifestyle (b) self-reports, regarding dietary and physical exercise habits, (c) cognitive-behavioral psychotherapeutic sessions.

Results: Visual analysis of the data on weight loss showed a faster rate of weight change (8.5 kg within 8 weeks) for the fluoxetine-treated patient, and a slower rate of weight change with variable data (6.2 kg within 24 weeks) for the olanzapine-treated patient.

Conclusions: Overall, the psychoeducation treatment package was effective for both patients. However, the different patterns of weight loss indicate that individualized responses to different types of medication and the nature of the psychiatric disorder, need to be considered in order to maximize the benefits of the psychoeducation treatment for each individual patient.

15. Tetsuro Ohmori

Aims/Objectives: The aim of the present study is to investigate the predictors of objective quality of life in people with schizophrenia.

Methods: Subjects were forty-nine stabilized outpatients with schizophrenia (DSM-IV). Their mean age was 39.7 (SD=11.7) years. All subjects signed a written informed consent form approved by the Ethics Committee of University of Tokushima. Objective quality of life and cognitive function were assessed using the Quality of Life Scale (QLS) and the Brief Assessment of Cognition in Schizophrenia (BACS), respectively. Clinical symptoms were evaluated using the Positive and Negative Syndrome Scale (PANSS), the Calgary Depression Scale for Schizophrenia (CDSS), and the Drug-Induced Extrapyramidal Symptoms Scale (DIEPSS).

Results: The QLS scores significantly correlated with verbal memory score and attention score of the BACS. The QLS scores except instrumental role subscale score significantly correlated with working memory score of the BACS. Intrapsychic foundations subscale score of the QLS significantly correlated with verbal fluency score of the BACS. Moreover, the QLS scores significantly correlated with the PANSS positive syndrome scale score, the PANSS negative syndrome scale score, the CDSS score and the DIEPSS score. However, duration of illness, number of hospitalization, and dose of neuroleptics did not correlate with the QLS scores.

Conclusion: These results show that objective quality of life is not only associated with psychiatric symptoms but also is related to cognitive function, especially verbal memory, attention, and working memory.

NEGATIVE SEXUAL EXPERIENCES AMONG JAPANESE UNIVERSITY WOMEN AND ISSUES CONCERNING THE AFTERMATH

INSTITUTIONS
1. Kumamoto University Graduate School of Medical Sciences, Department of Clinical Behavioural Sciences (Psychological Medicine), Kumamoto, Japan

AUTHORS
1. Masayo Uji, Dr., PhD, ujimasayo@hotmail.co.jp

Aims/Objectives: 1. To delineate the prevalence of a negative sexual experience (NSE) and its characteristics among Japanese university women. 2. To examine whether the attribution style and shame-feeling contribute to developing PTSD.

Methods: 1. Questionnaires were distributed among 799 university women. They were asked about the characteristics of a NSE and also about the experience relating to the disclosure. 2. They completed the Abuse Attribution Inventory, Abuse Specific Shame Questionnaire and Impact of Event Scale. How the attribution style and shame-feeling contribute to developing PTSD was analyzed.

Results: 1. 40% of the respondents reported at least one NSE. Among them, 1.7% of the women were raped. More than 60% were victimized by strangers. About 5% were victimized by relatives. All the perpetrators except for one were male. Victimization by relatives, teachers, or classmates were more likely to be repeated. Most respondents disclosed their NSE to a friend or to their mother. The perception of the victim regarding their confidant’s reaction varied from individual to individual. 2. Internal attribution prompted shame-feeling which in turn played a role in developing PTSD, although internal attribution did not have a direct impact in developing PTSD.

Conclusion: 1. A number of women reported a variety of NSEs, which means the awareness regarding sexual victimization and need for proper treatment are increasing. 2. The internal attribution and the shame-feeling are products of an interaction between an individual and social value of a particular culture, and these could result in maladjustment.

GUARDIANSHIP IN BRAZIL - A COMPARATIVE PERSPECTIVE

INSTITUTIONS
1. Federal University of Rio de Janeiro, Ethic and Forensic Psychiatry, Rio de Janeiro, Brazil

AUTHORS
1. Katia Mecler, Dr., PhD, katia@mecler.com.br
2. Mauro Victor Mendlowicz, Dr., PhD, mmendlowicz@yahoo.com
3. Alexandre Martins Valença, Dr., PhD, avalen@uol.com.br
4. Maria de Fatima Vasconcellos, Dr., MD, fatimav@centroin.com.br
5. Talvane Marins de Moraes, Dr., PhD, talvane@terra.com.br

Since 1960s, a broad wave of legal reforms in the fields of personal autonomy, decision-making and guardianship has swept the developed countries, enhancing the visibility of these critical issues worldwide. Brazil, however, having only recently reformed its adult guardianship laws, remained relatively impervious to the new winds. This study intends to inform the discussion surrounding adult guardianship law reforms from an international and comparative perspective. For this purpose, Brazil, France, Germany, Italy and the United States legislations were chosen as the base for comparison. Each jurisdiction had its adult guardianship law examined, including the historical background and recent developments. We found that there has been a significant shift from a paternalist-based model to an individual-rights-based regime across many jurisdictions around the world. Unlike other countries, Brazil has failed to significantly modernize its guardianship laws and faces a growing challenge to adapt it to the currently accepted international standards.

The imposition of guardianship creates important ethical, legal and practical challenges for the society, in general, and for the civil rights community, in particular. During the past 20 years, many countries have revised their guardianship laws or enacted comprehensive new provisions. However, very little is known about the reality of adult guardianship under the Brazil law. This study investigated the adult guardianship in Rio de Janeiro, Brazil, by examining court proceedings, with a particular focus on the profile of the wards, the reasons for requesting guardianship and the outcome of the wardship process. The study was a quantitative analysis, based on a random sample of 283 proceedings for legal guardianship of adults due to presumably impaired legal capacity. The legal papers of these cases were retrieved during the period extending from January 1st through December 31st, 2002 from four probate courts of the city of Rio de Janeiro that are specialized in cases of guardianship. Our findings revealed that adult guardianship in Rio de Janeiro, Brazil, is often imposed to vulnerable sub-groups of the population, such as poor, single individuals suffering with mental retardation or dementia, who need a social security pension to provide for minimum subsistence.

5. Diana Ojog³, Ms., MA

Objective: To assess the guided imagery techniques impact over the severity of depressive symptoms in patients diagnosed with breast cancer.

Methods: We evaluated a group of 22 female patients, mean age 46.3, diagnosed with breast cancer in the previous 2 months, that presented at the admission also a diagnosis of mixed anxious and depressive disorder. All our patients were expecting chemotherapy, radiotherapy and/or surgical treatment and presented negative perception of their body image and catastrophic cognitions about the effects of treatment methods. Guided imagery was used to create a new perception of the symptoms and to induce relaxation, to relieve muscle tension and to diminish the anxiety and depression associated with cancer [1]. We focused on goal achieving, creating positive expectations and relaxation [2]. We assessed these patients for 3 months, using Beck Depression Inventory (BDI) 21 items version and Global Assessment of Functioning (GAF), every 2 weeks.

Results: After 12 weeks (6 therapy sessions), our patients presented an improvement in their depressive symptoms (p<0.05), especially on items like pessimism (p<0.01), suicidal ideation (p<0.01), dislike of self (p<0.05). The GAF score also improved (p<0.05).

Conclusion: Guided imagery could relieve depressive symptoms, especially the cognitive distortions and is therefore an useful associated technique in the general approach to patients with breast cancer.

THE MANAGEMENT OF ALCOHOLISM DEPENDENCE IN PATIENTS WITH ONCOLOGIC DISEASE

INSTITUTIONS
1. CLINICAL EMERGENCY CENTRAL MILITARY HOSPITAL, PSYCHIATRY, BUCHAREST, Romania

AUTHORS
1. Daniel Vasile¹, Dr., MD, PhD
2. Octavian Vasiliiu¹, Dr., MD, PhD
3. Oana Cretu¹, Mrs., MD
4. Paul Ivanov¹, Mr., MD
5. Beatrice Stanescu¹, Mrs., MD

Objective: To evaluate the importance of therapeutic management in alcohol dependence and cancer dual diagnosis.

Methods: We assessed 16 patients, 12 male and 4 female, mean age 53.3, diagnosed with cancer and alcohol dependence. All our patients admitted an abusive alcohol consumption of at least one year previous to actual hospitalisation while their cancer diagnosis was established for at least 14 months ago. Alcohol could be considered a patient's dysfunctional coping tool when is confronted with the stress associated with cancer diagnosis. Therefore, the goal of crisis intervention is to restore the patient baseline behaviour using coping skills enhancement and problem solving techniques[1]. We used for assessment The Alcohol Use Disorders Identification Test (AUDIT) and Clinical Global Impressions (CGI) every 2 weeks for 3 months.

Results: The improvement on AUDIT was significant (p<0.05) at endpoint only in the majority of patients that participated in all the 12 sessions of the study (n=11). The CGI score paralleled the evolution of AUDIT (p<0.05) and decreased from 4.6 at baseline to an 2.1 endpoint value. A low compliance rate was registered as 3 patients missed at least 4 sessions and 2 patients missed at least 2 sessions.

Conclusion: The alcohol dependence in cancer diagnosed patients needs careful assessment and therapeutic management. Noncompliance and treatment discontinuation are significant in such patients due to the status of coping tool that alcoholism have in oncologic patients.

Psychiatric patients are stigmatized in their social environment - society, but also their families. Stigma that is widely spread is that they are dangerous and threat to the society. Their potential aggressiveness and criminogenic activity are constantly at the public focus, although official statistical records show otherwise. Criminal rate of psychiatric population is same or even lower than over-all population. Also, studies have reported that comorbid psychiatric syndromes and disorders are present in large number of patients and that these are the primary factor of aggressiveness, and not psychotic disorder itself. This study concerns only psychiatric syndromes and disorders as comorbidity, and not physical. Purpose of the study was to establish percentage of comorbid syndromes and disorders at the forensic patients that were at the Center due to security measures. They were diagnosed according to Diagnostic and Statistical Manual of Mental Disorders IV Revision, (abbr. DSM-IV) (American Psychiatric Association, 1994), using Structured Clinical Interview for DSM IV Axis I Disorders, Clinical Version (abbr. SCID I CV); Structured Clinical Interview for DSM IV Axis II Personality Disorders (abbr. SCID II). Research included 237 patients treated at the Center of Forensic Psychiatry. The results indicate significant presence of Substance Use Disorders. Psychotic patients also had a Personality Disorder Axis II diagnosis, beyond their basic psychotic disorder.

7. Polyxeni Nicolopoulou Stamatí, Associate Professor, MD, PhD
8. George N Papadimitriou⁵, Professor, MD,PhD

Aim: Despite the increasing interest of literature, the interaction between anxiety, depression, quality of life and the progress of inflammatory bowel disease (IBD) remains controversial. Our aim was to further investigate any interactions and to relate the results to the concentration of Heat Shock Protein70 (biomarker of cellular stress) in the histologic examination of the patients.

Method: The WHOQOL-BREF for QUALITY OF LIFE, the ZUNG DEPRESSION SCALE, STAI and the HAD Scale were administered to 58 patients (35 men/23 women), hospitalized in two general hospitals of Athens for a relapse of inflammatory bowel disease (36 ulcerative colitis, 21 Crohn’s disease, 1 intermediate colitis).

Results: A moderate negative correlation was observed within the domain of psychological health of WHOQOL-BREF and a) the Zung D.S. (r = -0.61,p<0.001),b) the STAI Form X1 (state)(r= -0.665,p<0.001) and c) the depression subscale of HAD (r= -0.609,p<0.01).Moreover, the mean of anxiety as trait (STAI Form X1) in men (M=46.00,SD=9.97) was significantly higher (t = 3.10, df=54,p=0.003) than that of men (M=38.50,SD=8.71). Conclusion: Further research in IBD patients is needed, in order to clarify the emerging correlation between quality of life (psychological health domain) and anxiety/depression as well as sex differences within these parameters.

EVALUATION OF THE MEDICAL INTERVIEW BY SYSTEMATIC VIDEOTAPING OF STUDENTS

INSTITUTIONS
1. Universidad de los Andes - Medical School, Psychiatry, Santiago, Chile

AUTHORS
1. Kristina E. Weil, Associated Professor, MD, kweil@uandes.cl
2. Rogelio H. Altuzarra, Professor, MD, raltuzarra@uandes.cl

More than 65% of medical diagnoses are based exclusively on the clinical encounter, but the curriculum of medicine study allots a small amount of time to teaching communication skills. We assume that the students will improve the quality of their medical interviews with the advancement of the career, but to date no objective measure has been presented in support of this belief. Medical students of different study levels within the Universidad de los Andes in Santiago de Chile were videotaped during a clinical encounter with a standardized patient, and evaluated by the Brown Evaluating Interview Scale. Partial and global scores were compared and statistically analyzed, leading to conclusions about the evolution of the quality of the medical interview and its possible relationship with socio-demographic aspects and other relevant variables. No significant differences appeared in the Global Brown Scale considering study level and gender, but the score was better according to the academic performance of the students, and the patient they were exposed.

The task of covering the scientific advances of the last decades in neurosciences is onerous, given their tremendous growth and complexity, particularly in molecular biology. Among us, discussions on the "gap" and "bridges" between neurosciences and psychiatry are numerous. Yet, our training in neurosciences is rather poor. Reading E. Kandel could be the best way to review major trends in neurobiology and give robust ground for discussions, based on his contribution to learning and memory. In "In search of memory", we can watch Kandel's personal itinerary and experiments step by step: learning is a change in the functional effectiveness of previously existing excitatory connections. Short-term memory is linked to functional changes in existing synapses, while long-term memory is associated with a change in the number of synaptic connections.

Kandel also deals with basic questions on brain development, cell communication, perceptions and motor acts. How is communication between neurones modified by experience? by disease? As psychoanalysts, the material we work on is memory traces. As psychiatrists, we try to promote changes. We need to have some knowledge on the brain functions, but we need to be careful in identifying gaps in knowledge and limits in understanding. Regarding human behaviour and psychiatric diseases, there is room for questions on Kandel's assumptions. We wish to open discussion of the proposed genetic features and neurobiological bases of psychiatric disorders, the neural underpinnings of psychopharmacological interventions. And see how far we can go into Kandel's proposal of a "new frame for psychiatry".

PAIN AND ANXIETY OWN EXPERIENCES

INSTITUTIONS
1. Psychiatric Ward, Public Hospital, Chrzanow, Poland

AUTHORS
1. Jaroslaw P Wozniak¹, Dr, MD, panjaros@post.pl

Aims/Objectives: The attempt to interest the doctors of the different specialties - thepsychical state with inclusion of fear disorder among patients with chronic pain. The world literature run after the latest reports about the methods of curing the pain. Because of the quickly evolving technology we are able more precisely explain the cause of the pain but on the basis of the twenty years of practice I'm under the impression that slowly our patient begins to get lost us between the diagnosis and treatment. We lose contact as with human being.

Methods: Elaboration and leading in conformity to own authorial program the educational workshops for doctors, nurses, social workers and guardians of the patients with chronic pain.

Results: Considerable increase of amount of the patients directed for psychiatric consultations by doctors engaged with the pain issue what brought about improvement of life quality among patients, whom applied anti anxiety treatment, also patients in the terminal state.

Conclusion: There's no pain without anxiety.

4. Serap Yıldırım³, Mrs., camserap@yahoo.com

Aim: The aim of the study was to determine the relationship between postpartum depression and social support in women.

Method: This descriptive studies’ sample consisted of 240 women who gave birth of eight district health centers of Bornova in Izmir, Turkey. The data was collected with two questionnaires; Edinburgh Postpartum Depression Scale (EPDS) (1) and Social Support and Multidimensional Scale of Perceived Social Support (MSPSS) (2). Data were analyzed by Pearson Correlation Test (p<0.01).

Results: The average age of women was 27.34±4.64 years, the 34.5 % of women were high school graduates, 26.4 % were working at a job and 85.7 % have nucleus-type family. The duration of marriage was 5.53±4.29 years, 85.7 % became pregnant with their own will and 74.7 % became programmed pregnancy. The depression ratio was found as 31.9 %, EPDS as 9.05±5.98 and MSPSS as 57.79±13.97. There was a negative relationship between postpartum depression and social support (r= -0.308; p<0.01). It was found that the higher relationships between postpartum depression and sub-groups of social supports were family (r= -0.296; p<0.01).

Conclusion: It seems that women who gave birth had postpartum depression and this depression was associated with social support provided by family members.

3. Serap Yıldırım¹, Mrs., canserap@yahoo.com
4. Hale Uyar Hazar², Mrs., hazarhale@gmail.com

Objective: The study was conducted to evaluate the relationship between the psychiatric symptoms of primiparous pregnant women and the ways of cope with stress.

Method: This descriptive and relational research was carried out between 15th June - 1st February 2006 at The Department of Obstetrics and Gynecology of University and Government Hospital in Turkey. The sample of the study was 220 primiparous pregnant women who agreed to take part in the research. The data was collected with two questionnaires; SCL-90-R (1) and the Scale of the Ways to Cope with Stress (2).

Results: The average age of pregnant women was 25.35±5.56, 57.3% became pregnant within the first year of marriage and 89.1% became pregnant with their own will. It was found that the scores of General Symptom Index (GSI) and the Ways to Cope with Stress sub-scales such as “self-confident approach”, “optimistic approach” and “search for social support” had a negative relationship whereas “desperate approach” and “obedient approach” had a positive relationship which also indicated a statistically meaningful relationship (p<0.01).

Conclusion: When the GSI level of pregnant women was increased, the level of “self-confident approach”, “optimistic approach” and “search for social support” were decreased whereas the level of “desperate approach” and “obedient approach” were increased.

THE MYTH OF THE BEAUTIFUL, SLIM AND YOUNG WOMAN

INSTITUTIONS
1. Women’s Chapter APSA, Buenos Aires, Argentina

AUTHORS
1. Diana Zalzman¹

An overview of the XXI century, focus on body transformations. “Century of the Image” or “Civilization of the body”. For many, the worry over the image of the body ranges from passion to obsession until it becomes an addiction. Our society attaches great significance to personal appearance and the media systematically reinforces the message that “beauty succeeds”. Unlimited consumerism has led to the concept of “who you are is determined by the way you look”, BEING AND APPEARING TO BE go hand in hand.

The leadership enjoyed by fashionable models, actors and actresses over some segments of the population, together with the existence of certain physical stereotypes which are deemed desirable, has given rise a great demand for treatments aimed at modifying the body (plastic surgery, liposuction, implants), which in many cases are presented as the solution to existential or life problems or as guaranteeing accesses to success in relationships. If each individual’s specific psychopathology is not taken into account (i.e. dysmorphophobia cases) the consequences of these treatments will go from dissatisfaction to depression and in more dramatic cases to real physical sequel, which I will illustrate with graphics.

BOOK SIGNING WITH PROFESSORS NORMAN SARTORIUS AND JULIO ARBOLEDA-FLÓREZ

Professors Norman Sartorius and Julio Arboleda-Flórez will be signing their new book, Understanding the Stigma of Mental Illness: Theory and Interventions, Sunday, 21 September, 2008, from 15.00–16.45, and Wednesday, 24 September, 2008, from 11.00–12.00 at the Eli Lilly and Company/Boehringer Ingelheim GmbH booth. Line space and book quantities may be limited, so please arrive early to meet the authors.
Cipralex - the power to tackle depression & anxiety at its core

Presentation “Cipralex”, tablets containing 5, 10 and 20 mg escitalopram (as oxalate).

Dosage Usual dose 10 mg once daily. Maximum dose 20 mg/day. In the elderly (>65 years), in panic disorder patients and in patients with reduced hepatic function an initial dose of 5 mg/day is recommended. Caution in patients with severely reduced renal function. Not recommended in children and adolescents (<18 years). When stopping treatment with escitalopram, the dose should be gradually reduced over a period of one or two weeks.

Contraindications Hypersensitivity to escitalopram. Concomitant treatment with non-selective MAOIs. Pregnancy and lactation Careful consideration prior to use in pregnant women. Breast-feeding women should not be treated.

Precautions The special warnings and precautions which apply to the class of SSRIs. Drug interactions Reversible, selective MAOIs. Selegiline (irreversible MAO-B inhibitor). Medicinal products lowering the seizure threshold. St. John’s Wort. Enzyme inhibitors (e.g. omeprazole and cimetidine) may require reduction of escitalopram dose. Drugs metabolised by enzymes CYP 2D6 or 2C19.

Adverse events Adverse events, most frequent during first or second weeks, comprise the SSRI class adverse events, e.g. nausea, diarrhoea, and constipation.

Overdosage Doses between 400 and 800 mg of escitalopram alone have been taken without any severe symptoms. Consult full prescribing information before prescribing.

H. Lundbeck A/S, Copenhagen, Denmark. Date of preparation: January 2007
