MUNCHAUSEN BY PROXY SYNDROME AS A BOND PHENOMENON

INSTITUTIONS
1. Minors Penal Family Court. Judiciary Power, Mendoza, Argentina
2. Pediatric Hospital Humberto Notti, Mendoza, Argentina

AUTHORS
1. Analía V. González Sabatini, Psychologist, MD Criminology, analiavero_gonzalez@yahoo.com.ar
2. María de los Angeles Quiroga, Psychiatrist
3. María I. Foschi, Pediatrician

Objectives: Find out characteristics linking victims, offenders, non-offenders, medical staff. Find out offender’s personality traits/disorders and his influence in the bond.

Methods: Five cases with Munchausen by Proxy Syndrome (MBPS) were studied in the judiciary system that protects children. They were previously evaluated by pediatrician according to Meadow (1) system and medical examinations. Psychological/psychiatric evaluation of people in charge of children was taken and diagnosis was confirmed according to DSMIV-TR. Techniques: The Minnesota Personality Test (MMPI 2), interviews and medical histories revision. A transversal, descriptive and retrospective work with qualitative/quantitative variants was done with frequency tables using SPSS.

Results: Before five years old, 100% of children started showing produced and simulated symptoms, the methods used were potentially deadly (intoxication, suffocation). Children were in hospital and tests were taken repeatedly. 100% of offenders were biological mothers. 100 % of fathers believed in children’s “illness” and only mothers were in charge of them. Women’s bonds were characterized by manipulation and cheating. 100% showed antisocial personality disorders and narcissist traits (DSMIV-TR). Diagnoses were confirmed with MMPI 2 and interviews.

Conclusions: MBPS is a pathological bond involving four protagonists: child/offender/non offender/medical staff. Offenders manipulate others generating reiterative medical interventions, couples are convinced of child’s illness and maternal cares, and a “sick” child who is unprotected if syndrome is not suspected. Considering the relationship among participants help see a wider picture of this syndrome and diagnosis.

As a rule, mentally ill patients are held responsible for their acts just like everyone else. Notwithstanding, the law in most countries distinguishes individuals with mental illness from others. The Court usually releases a defendant from criminal responsibility when the following criteria are met: (a) the defendant was mentally ill, (b) he/she was in a psychotic state at the time he performed the felony, (c) his/her mental illness deprived him/her of his/her abilities. In the case presented, a mentally ill individual was charged with the murder of his child and with an attempt to murder another child. The court ruled him to be legally insane and therefore non-punishable. He was later sued by the other child’s parents for damages on the grounds of the assault tort. The court ruled that a mentally ill person must compensate for damages when he/she intended to cause harm, since compensation for damages is the essence of claims in torts. The Supreme Court ruled that the Israeli Tort Law did not determine exemption from responsibility for the mentally ill. Liability for damages will be imposed upon an individual whenever the prerequisites to define a tort are met, and an individual who intended to inflict harm is guilty of assault, even though the intent was an outcome of his mental state. Should psychiatrists adjust the vantage point when writing expert opinions concerning damages? This issue will be discussed.

TAKING MENTAL HEALTH TO SCHOOLS: THE “CRAZY? SO WHAT!” PROGRAMME

INSTITUTIONS
1. Universitätsklinikum-Zentrum f.psych.Gesundh, Irrsinnig Menschlich e.V, Leipzig, Germany
2. North Carolina State University, Department of Public Administration, Durham, NC, United States

AUTHORS
1. Petr B Nawka1, MUDr., MD, pnawka@t-online.de
2. Conrad Ines2, Mrs., PhD, ines_winkler@yahoo.de
3. Charlene M. Reiss2, Ms., MPA, charalt2004@yahoo.com

Aims/Objectives: This study evaluated the health-promoting and stigma-reducing effects of the school-based programme “Crazy? So what!” (1). From 2001 until 2007, 7000 pupils took part in this programme in Germany, as well as 700 pupils in Prague, Czech Republic and Michalovce, Slovakia. The unique core of this school programme is the direct contact between pupils and people with mental health problems.

Method: In Germany, 210 pupils in Years 9 and 10 (aged 13 - 18 years) were surveyed in four schools.

Results: In the event of a mental health crisis, 80.9% of the pupils would talk to their best friend. At baseline, only 5.2% of the intervention group would talk with their teacher about a mental health problem. Immediately after the programme, this number increased to 10.6% and after 3 months to 17.9%. In addition, a positive, short-term effect on pupils’ social distance was shown. By contrast, self-efficacy proved resistant to change within this project.

Conclusion: The school programme has successfully enabled youth “experts on their own behalf” to encourage and reassure pupils to face a mental health crisis with more confidence. The results of this study indicate the importance of sensitising children and youth, but also teachers and other adults to mental health.

THE IMPLICATIONS OF SEROTONIN TRANSPORTER GENE VARIATION IN STRESS RESPONSE

INSTITUTIONS
1. Mayo Clinic, Psychiatry and Psychology, Rochester MN, United States

AUTHORS
1. Gen Shinozaki¹, Dr., MD, Shinozaki.Gen@mayo.edu
2. David A Mrazek¹, Dr, MD, Mrazek.David@mayo.edu

Aims/Objectives: The serotonin transporter gene (SLC6A4) indel promoter (5HTTLPR) has been associated with individual stress response as well as mental illnesses including depression, bipolar disorder, alcoholism, and personality disorder. Caspi et al. showed that individuals maltreated in childhood have higher rates of depression in later life if they are homozygous short (S/S) compared to homozygous long (L/L) (1). We hypothesized that these findings should be explained by a molecular functional difference of the serotonin transporter gene, especially its capacity of absorption of serotonin.

Methods: Integrated model of SLC6A4 was employed to explain accumulating results of recent investigations exploring the relationship between the genotype in serotonin transporter and the phenotype in depression. Relevant literature was reviewed to examine this theory.

Results: A model based on SLC6A4 variation was proposed to explain individual differences in stress vulnerability/resilience based on genotypic difference. Tryptophane depletion shows that efficient serotonin reuptake and reuse at the local synaptic site facilitates smooth neurotransmission and subsequently appropriate cognitive function (2). Differences in stress induced physiological responses also support the contribution of genotypic differences based on this model.

Conclusions: This integrated model of 5HTTLPR shows that the efficacy of serotonin reuptake in local synaptic site may be playing a crucial role as a pathophysiology of depression.

PSYCHIATRY FOR THE PERSON SHOULD NOT BE CONFINED TO THE CLINIC ONLY

INSTITUTIONS
1. Calcutta Pavlov Hospital, Kolkata, psychiatry, Kolkata, India

AUTHORS
1. Asis Krishna Acharya, Dr., D.I.H, D.P.M, dr_asisacharya@yahoo.com

Objectives: Psychiatry in past had attached many stigmas, and was subjected to harsh nonhumanitarian treatment for a long. Philippe Pinel in 1795 in Paris, was first to accord Humanitarian treatment to asylum inmate females by cutting their chains with cutters and make them free to live a normal human life. More than 200 years have flown in between, still the scenario remains gloomy and beyond satisfaction. Psychiatry in developing country is mostly confined in clinics & hospital settings only.

Methods: About 50 Psychiatrist, attending own personal clinic and hospital were interviewed about their devotion of time to clinic and hospital and also to any community activities like awareness increasing programme etc. in Calcutta in 2007.

Results: Their allocation of time is 80-85% in diagnosis and prescribing drugs only. 5% reported some devotion of time in awareness, or screening or school mental health programme 1-2 per year that amounts to their 2% time investment. As a whole total duration of 50 Psychiatrist put together is >1%.

Conclusions: Psychiatry for the person is suffocating in small clinics or in closed hospital where whoever ill may come and consult, and receive treatment. After Pinel 1795, chains had been cut but innumerable chains and stigmas, invisible, is there. We need to free those invisible chains and to add 2 wings to the Psychiatry so that it can fly or move to the mass specially in crisis, in distress or in so many live situations where psychiatry help can reach and make them at ease. Psychiatry in future will be in community. Psychiatry should by this way meaningfully moved to personhood rather than patienthood.

RESEARCH OF PSYCHOLOGICAL HEALTH OF THE STUDENTS LEARNING IN HIGHER SCHOOLS OF ARMENIA

INSTITUTIONS
1. Yerevan State Medical University, Medical Psychology, Yerevan, Armenia

AUTHORS
1. Gayane A Ghazaryan, Mrs, kgy@rambler.ru

The purpose of our research was the study of mental health of the students learning in higher schools of Armenia and working out of the recommendations on psychological maintenance of education in higher schools. 212 students in the age of 18-22 participated in the research. The psychological tests have been done with use of Lasher 8 colour tests; techniques of a self-estimation diagnostics by D.Spilber, L.Hanine, Cattell’s 16-Facter Questionnaire, Eysenck - EPQ Technique. By the results of inspection, depending on the nervous-psychic stability, the observable were divided into 3 subgroups: First group included 29,72 % examinees having high parameters of personal uneasiness. The high uneasiness assumes tendency to an alarm condition in the human when estimating his competence, that proves to be true by our researches. Thus the factor MD - „adequacy of a self-estimation „ from Cattell’s 16-Facter Questionnaire, by 11 % is lower, than in people with low parameters of personal uneasiness. The second group included the overwhelming majority of our examinees (65,09 %), whose parameters personal uneasiness is average, which is positive characteristic. The third group included persons with low personal uneasiness (5,19 %). The initial item of planning of preventive maintenance of stress in students’ environment can be perception of the nearest neighborhood as benevolent, having high personal importance, expectation of a positive reinforcement, anticipation of positive effects of the activity expand socio-psychological competence of the individual.

ILLNESS BEHAVIOUR IN MENTAL HEALTH

INSTITUTIONS
1. Dunedin School of Medicine, Psychological Medicine, Dunedin, New Zealand

AUTHORS
1. Richard Mullen, Dr., MRCPsych. PhD., richard.mullen@stonebow.otago.ac.nz

Aim: Illness behaviour refers to the ways in which symptoms are experienced, evaluated and acted upon by individuals. It is usually considered in relation to physical disorders. This theoretical paper aims to apply concepts of illness behaviour to mental disorders.

Method: Hypothesized determinants of disturbed illness behaviour such as secondary gain, interpersonal expediency, clinical over-investigation, attention to otherwise trivial symptoms, and compensation are examined for potential relevance in mental disorders.

Result: Mental disorders differ from physical disorders in ways that complicate thinking about illness behaviour. However those factors that influence illness behaviour in physical illness are also likely to be relevant for mental disorders. Mental disorders are increasingly acknowledged as valid reasons for occupation of the sick role, so an increase in disturbed illness behaviour in mental health is likely.

Conclusions: The study of illness behaviour in mental disorder presents conceptual and practical problems, but may illuminate some of the important determinants of much mental disorder and associated help seeking behaviour.

STIGMA ON MENTAL ILLNESS CAN BE REMOVED SUBSTANTIALLY - A FOLLOW UP STUDY AFTER 5 YEARS IN RURAL INDIA.

INSTITUTIONS
1. Global Mental Health Institute, Social Psychiatry, India

AUTHORS
1. Hiranmay Saha1, Mr., MD, dr_hahaha@yahoo.co.in

Aims: Previously 5 years back we have seen that faith healers were very popular for the treatment of mentally ills in rural India. Our aim in this study is to see whether there is any improvement in the old concepts after 5 years.

Methods: To study this, a follow up study was conducted after 5 years with almost same sample, same questionnaire and same rural area of West Bengal, India.

Findings: Stigma on mental illness is very less in comparison to previous studies. Most of them agree to consult physicians in mental illness and 50% of them intended to consult psychiatrists. Most of them consider depressive illness is a disease. Psychotropic drugs to be continued as advised by physicians. Most of them now believe that psychotropic drugs are not addictive.

Conclusion: Continuous awareness campaign helps a lot for improving the attitude and scientific knowledge of the people regarding psychiatric illness.

4. Thomas Zidek1, Dr., MD, tzidek@yahoo.com

Objectives: The stigma of mental illness is well established as a complicating feature of psychiatric suffering and treatment, especially in schizophrenia [1]. Individuals’ capacity to counteract stigma is conceptualized as Stigma Resistance (SR) and may play a crucial role in the fight against stigma. The aim of this study was to explore determinants of SR in patients with schizophrenia or schizoaffective disorder.

Methods: 157 participants completed the “Internalized Stigma of Mental Illness” scale [2] including its subscale on SR as well as measures of perceived devaluation and discrimination, depression, self-esteem, empowerment, quality of life, demographic and clinical variables.

Results: 63% of all participants hold stigma resisting convictions. Correlations of SR with other constructs were as expected except for Discrimination Experience, which did not correlate significantly.

Conclusions: SR is a new and promising concept, which can be easily assessed. Strategies focusing on empowerment and quality of life may enhance SR.

MENTAL HEALTH VS. PSYCHIATRY

INSTITUTIONS
1. University of Medicine and Pharmacy, Clinic of Psychiatry, Craiova, Romania

AUTHORS
1. Tudor Udristoiu1, Professor, MD, PhD, office@psycv.ro
2. Ion Udristoiu1, Dr., MD, monarist@gmail.com

During the last decades, many declarations, resolutions and slogans have been promoted in relation with mental health.

This significant amount of words has a negative impact on the position and role of Psychiatry as a medical specialty, which might lead to its marginalization, dilution and even disappearance.

Although scientific research clearly supports the biological model of mental disorders, the planning of services and organization of care are more and more social and less medical. The consequence is the deviation from the scientific evidence (more than 20% of the patients is "treated" without doctor, the treatment gaps are widening, the medication represents less than 5% of the costs) and the allocation of funds is far from covering the needs. The replacement of "mental disorders" with "poor mental health", of "psychiatric treatment" with "positive mental health promotion" and "antistigma projects" is not meant to bring real benefits to our patients. We believe that the fundamental rights of every patient are the right for adequate treatment and the right for recovery and social reintegration.

Being unconditioned defenders of the patients’ rights and dignity, we plead: a) to defend the statute of Psychiatry as a medical specialty; b) to separate - both in planning and in funding - clinical psychiatry (secondary prevention and rehabilitation) from mental health promotion; c) to consider the patients with mental disorders as patients like all others, while keeping in mind the specificity of their suffering; d) same ethical rules and rights for psychiatrists with those of the colleagues in other specialties.

OC-12-08
COMPLIANCE VERSUS FREEDOM; WHAT IS BEHIND THE CHOICE?

INSTITUTIONS
1. Empangeni Garden Clinic, Private Practice, Empangeni, South Africa

AUTHORS
1. Bogdan T Latecki1, Dr, MD, latecki@iafrica.com

There are many ways to exercise one's freedom and there is a consensus that „The right to swing my fist ends where the other man’s nose begins.” Matters become more complicated when it comes to your own nose.

The paper discusses the situation when the corpus mentis patient decides not to be compliant with treatment, in other words - takes freedom from dependency on medications. The possible reasons for such a choice, including psychodynamic, philosophical and psychoanalytical (referring to Transactional Analysis theory) are discussed.

The practical approach, in which the patient is presented with the options of exercising his freedom from treatment, and resorting to his "strong will" and expectancy to be "in luck", as opposed to the option of renouncing his freedom in favour of compliance, in hope for more safety and comfort, is presented.

The analogies social and political cases are quoted. Consideration is given to the fact that our tendency of valuing and exercising free will, understood as "relying on self" rather than, relying on support changes during the course of life.

IMMIGRANTS LIVING IN EXTREME SITUATION: IMMIGRANT SYNDROME WITH CHRONIC AND MULTIPLE STRESS (THE ULYSSES SYNDROME)

INSTITUTIONS
1. University of Barcelona, SAPPIR, Barcelona, Spain

AUTHORS
1. Joseba Achotegui1, Mr, MD, sappir@terra.es

Today, the circumstances in which many immigrants come to Europe present stress levels of such intensity that they exceed the human capacity of adaptation. These persons are, therefore, highly vulnerable to Immigrant Syndrome with Chronic and Multiple Stress, known as the Ulysses Syndrome (in reference to the Greek hero who suffered countless adversities and dangers in lands far from his loved ones). The most important stressors are the enforced separation of the one’s loved ones, the failure to achieve one’s objectives, the experiencing of extreme hardships and terror. Furthermore, the stressors are chronic and without network of social support. The symptomatological expression of Ulysses Syndrome is a specific combination of symptom of the area of depression, symptoms of the area of anxiety, somatic symptoms and confussional symptoms. The Ulysses Syndrome forms a gateway between mental health and mental disorder The Ulysses Syndrome is found in the area of preventative health care and the psychosocial sector more than in the area of the psychopathology. Loneliness, fear, despair ... the migrations of this new millennium remind us increasingly of Homers’ verses, the text in which Ulysses tells Polyphem: “You ask me my name. I shall tell you. My name is nobody and nobody is what everyone calls me”. (Odyssey, Song IX, 360) It is clear that if a man has to become a nobody in order to survive, if he has to remain permanently invisible, he will have no identity, will never become socially integrated, self-esteem, nor will he enjoy mental health.

„NERVES“: A CULTURAL PATTERN FOR COMMON MENTAL DISORDERS?

INSTITUTIONS
1. University of Rio de Janeiro State, Medical Sciences School, Rio de Janeiro, Brazil
2. National School of Public Health, Social Sciences Department, Rio de Janeiro, Brazil
3. University of Rio de Janeiro State, Social Medicine Institute, Rio de Janeiro, Brazil

AUTHORS
1. Sandra Fortes1, Dr., PhD, sandrafortes@gmail.com
2. Monica R. Campos2, Dr., PhD
3. Claudia S. Lopes3, Dr., PhD

Introduction: “Nerves” are a frequent complaint among Latin American patients. In psychiatric classifications „Ataque de nervios” is considered a cultural-bound syndrome, but its association with other psychiatric syndromes has been demonstrated. Sociological and anthropological studies in Brazil concluded that “suffering from nerves” is a cultural way of expressing psychosocial suffering among medical patients.

Objectives: To study if “nerves” can be considered a cultural pattern of presenting mental suffering. To evaluate the association between “nerves” and common mental disorders (CMD)

Methodology: A cross sectional study with 714 patients attending medical consultations in primary care units in Petropolis, Rio de Janeiro State, Brazil. CMD were detected using the General Health Questionnaire12, with 2/3 (GHQ3) and 4/5 (GHQ5) cut-off points. Two questions evaluated if the patients suffered from “nerves” and the period involved (15 days and 2 years). The association between “nerves”, CMD and other complaints (psychological, physical and medically unexplained ones) was studied using Chi-Square in a SPSS version10.

Results: The presence of CMD was strongly associated with the “nerves” complaints (OR 9.2, 95%CI 6.4-13.3, 15 days period and OR=4.8, 95%CI 3.1-7.3, 2 years period). “Suffering from nerves” was also the type of complaint most strongly associate with CMD, especially in less severe patients (GHQ3).

Conclusions: The majority of our patients with CMD (usually with anxiety and depressive syndromes) considered that they suffered from “nerves”, supporting the idea that, more than a specific syndrome, “nerves” can be considered a cultural pattern of communication of psychosocial suffering usually associated with common mental disorders.

NEUROLEPTIC-INDUCED MOVEMENT DISORDERS IN PSYCHOTIC PATIENTS WITHIN NORTHLAND DHB: ETHNIC VARIATION

INSTITUTIONS
1. Northland DHB, Psychiatry, Whangarei, New Zealand

AUTHORS
1. Valletta Tawhai1, Ms, Msc
2. Gloria Johnson1, Dr, FRANZCP

Introduction: There is a common perception within the New Zealand mental health community that patients from a Maori background develop more side effects, particularly movement disorders after treatment with neuroleptics.

Aims: This study investigated the point prevalence of extrapyramidal movement disorders in patients with chronic schizophrenia and related disorders who are currently treated by Northland DHB mental health services. The study also investigated evidence of variation in the point prevalence of these disorders based on the ethnicity of the patients (Maori and non Maori).

Methods: 151 patients, who were receiving antipsychotic medication, which had been commenced at least 3 months previously, were recruited as participants for the study using randomised computer software. Ethnicity was documented using self-identification. Standardised assessment tools were used to assess EPS.

Results: Approximately 54% had symptoms on at least one of the measuring scales. The analysis failed to show any statistically significant differences based on ethnicity (Maori and non Maori). However, the Maori subgroup was younger and there was trend for Maori to score more highly on some subscales.

Conclusion: The findings suggest that the prevalence of neuroleptic-induced movement disorders in psychotic patients within Northland DHB is similar to the documented international figures (up to 60%). The findings also indicate that there is no significant difference based on ethnicity between Maori and non Maori in terms of overall prevalence of movement disorder.

SEVERAL ISSUES RELATED TO CULTURAL ASPECTS OF FAMILY INTERVENTION INTENDED TO RELAPSE PREVENTION AMONG THE PATIENTS WITH SCHIZOPHRENIA

INSTITUTIONS
1. Azerbaijan Psychiatric Association, Secretary on projects, Baku, Azerbaijan
2. Azerbaijan Psychiatric Association, Innovation Committee, Baku, Azerbaijan

AUTHORS
1. Fidan Iskander Mammadova1, Dr., MD, dr_fidan@yahoo.com
2. Murad Zeynal Sultanov2, Dr., MD, dr.murad.sultanov@gmail.com

Family interventions are considered one of the important tools in prevention programs aimed to patients with schizophrenia. In this regard necessity of differential approach in family intervention programs for schizophrenia relapse prevention in different cultural context has come to the light. Meta-analysis of the results of the 26 researches on the expressed emotions in schizophrenia (conducted in 11 countries) in two years period relapse frequency of the patients, who lived in the families with high level of expressed emotions, is more than twice higher in comparison with families with low level of expressed emotions (66% vs. 29%) (1) However, according the conducted studies, these interventions revealed ambiguous result with regard to efficiency of them (2). Further researches are needed to determine effectiveness of the intervention in different cultural context. Based on the result of these studies, special adaptation of the intervention has to be developed. Ambiguity of the previously conducted studies is most probably related to cultural aspects involved in the application of this kind of intervention. Since the focus of the intervention is family, family interactions and relations, and this focus is very particular and has different cultural aspects vary in different ethnical contexts. It outlines importance of elaborating different models of the intervention for particular cultural context.

MIGRANTS RISK FOR PSYCHOSIS IN ANDORRA

INSTITUTIONS
1. Mental Health Services, Andorra

AUTHORS
1. Joan Obiols¹, Dr., MD, PhD, jobiols@andorra.ad
2. N. Cerulla¹
3. E. Bayona¹

There is a long standing controversy in the field of transcultural psychiatry regarding the link between psychotic conditions and migration. Andorra is a country with a very high proportion of migrant population, about 70%. Our group studied the incidence of new cases of psychosis for a period of 3 years, with the goal to compare the Andorran and the migrant population. It has to be mentioned that Andorra is considered a “micro-state” and the total population number about 80,000 inhabitants.

The main findings of the study are:
1) as a whole, there is a low incidence of psychotic first episodes in Andorra.
2) this low incidence is specially marked in the Andorran, Spanish and French population groups.
3) the groups showing a higher incidence are Portuguese, from other countries and second generation migrants.

It has to be said that these groups are associated with harder socio-economic conditions and the presence of stressful factors. Beyond the limitations of this study due to the low number of cases, the main conclusion is that, in Andorra, being an immigrant does not represent by itself a risk factor but the economic and cultural stressors associated in some cases represent a risk for a segment of the migrant population.

HOW TO ASSESS THE RESULTS OF MENTAL HEALTH REFORM - THE OUTCOME MEASURES

INSTITUTIONS
1. Institute of Psychiatry and Neurology, Center of Mental Health, Warsaw, Poland

AUTHORS
1. Malgorzata Pawlowska¹, Ms, MA, malgorzata.pawlowska@gmail.com
2. Katarzyna Prot-Klinger¹, Mrs, PhD, kasiaprot@gmail.com

The purpose of this presentation is to describe the various methods of assessing the treatment outcomes while undergoing the Mental Health Reform. At present, the primary model of mental health care in Poland is hospital centred, with coexisting ambulatory care, though in the absence of active community care. Social Welfare Act (1990) as well as Mental Health Act (1994) will be presented as an examples of Polish legislation, introducing serious restrictions on the involuntary admissions of psychiatric patients as well as community care, as primary tool of treatment. So far the main goal of Mental Health Program, transformation from hospital-based to community-based psychiatry, is far from being achieved. This situation give rise to the new version of Mental Health Program aiming mental health promotion and prevention, introducing new community model of treatment, establishing, monitoring and evaluating of new mental health system. The new Mental Health Program objectives will be introduced in detail. The results from efficacy and satisfaction study will be presented as an example of outcomes measuring. It is planned to introduce therapeutic relationship as a new tool assessing treatment efficacy. Evaluation of Mental Health Reform, recommended by WHO as world’s standards, is an important research goal. It is hoped that it will contribute to the development of community psychiatry in Poland as well as growing understanding of mentally ill problems by the Polish society and authorities, facilitating Mental Health Reform.

AN OVERVIEW OF HOMELESSNESS AND MENTAL HEALTH IN NEW YORK CITY IN THE LAST DECADE

INSTITUTIONS
1. Columbia University, Epidemiology Department, New York, United States
2. Reinier va Arkel Psychiatric Services, ‘s-Hertogenbosch, The Netherlands

AUTHORS
1. Elie S Valencia, Dr., JD, MA, esv1@columbia.edu
2. Helga V Saez, Dr, MD
3. Jaap Kool, Dr, MD

Objective: To provide an overview of homelessness and mental health in New York City (NYC) in the last decade.

Methods: This research is based on analysis of the main reports and studies on NYC homelessness and mental health and NYC Shelter System Register data.

Results: In 2006, the NYC homeless population was estimated at about 40,000 for any single day. Between 1994-2004, NYC shelters provided services to 416,720 individuals, including 163,438 children. The majority came from impoverished NYC areas. Many came from incarceration, streets and hospitals. Most were minority, particularly African-American. Homelessness had a major impact on morbidity and mortality. For 2001-2003, the HIV/AIDS estimated prevalence of the shelter population was twice that of the NYC adult population, and TB rate was 11 times higher. Two out of three of the hospitalizations were due to substance and alcohol use or mental illness (MI). Between 40-50 percent of single adults users are estimated to have a MI, however, the incidence over several years is much lower. A considerable number had a co-occurring MI and substance abuse history. Their death rate was twice that of the NYC population. Their leading deaths causes were heart disease, cancer, HIV/AIDS and substance abuse.

Conclusions: NYC has developed the most extensive shelter service system for homeless people in the world. However, a crisis management approach, rather that addressing the roots of homelessness, has characterized its overall policy. Currently, there is a shift to an approach which seeks to drastically reduce homelessness in the next decade.

OC-13-08
CRITICAL TIME INTERVENTION FOR PEOPLE WITH SCHIZOPHRENIA AND HOMELESSNESS IN HOLLAND

INSTITUTIONS
1. Columbia University, Epidemiology Department, New York, United States
2. Parnassia Psychiatric Institute, The Hague, The Netherlands

AUTHORS
1. Elie S Valencia, Dr., JD, MA, esv1@columbia.edu
2. Albert van Hermert, Dr., MD, PhD
3. Annicka van der Plas, Mrs, MA
4. Diede Schols, Dr, MD
5. Hans W Hoek, Dr., MD, PhD.

Objective: To adapt the evidence-based Critical Time Intervention (CTI) for use among people with schizophrenia and homelessness in The Hague. CTI is a time-limited, manualized case management approach to enhance continuity of care for severe mentally ill (SMI) by bridging the gap between services. CTI was found effective in a randomized clinical trial among homeless SMI people in New York (Susser, Valencia, 1997).

Methods: Study was implemented in three inter-related phases. First, electronic records of schizophrenia spectrum disorders patients (N: 2723) of The Hague's psychiatric services provider were screened to identify those with homelessness in the prior year (N: 112). Case Register data on service use (12-month), demographics and clinical variables were collected. In semi-structure interviews, we assessed a representative sample (N:59) for homelessness and instability patterns. Second, CTI was adapted and a manual produced. Third, the feasibility of providing CTI to some participants was tested.

Results: There was no significant difference on service use, demographic and clinical characteristics between participants (N:59) and no-participants (N:53). Analysis focused on factors which may mediate the CTI effect. The majority reported lifelong substance use: 64% cocaine, 36% heroine, 25% amphetamine; 63% cannabis, 53% alcohol. Current use was considerable: 32% cocaine, 10% heroine, 15% amphetamine, 52% cannabis, 34% alcohol. Most reported incarceration histories (76%). Prescribed medication histories were high (78%). The adaptation and its feasibility implementation were completed.

Conclusion: This study suggests that evidence-based interventions for people with SMI and homelessness, such as CTI, can be successfully adapted to meet the needs of specific groups.
OC-13-09
IMPLEMENTATION OF THE BREMEN RISC ASSESSMENT SCALE FOR GENERAL PSYCHIATRY (BRAS-GP)

INSTITUTIONS
1. Klinikum Bremen-Ost, Bremen, Germany

AUTHORS
1. Sebastian von Berg¹, Dr., sebastian.vonberg@klinikum-bremen-ost.de
2. Helmut Haselbeck¹, Prof. Dr., helmut.haselbeck@klinikum

Objective: Acts of violence caused by mentally ill people in Bremen in the year 2002 lead to an enforced public and medial discussion about how effective and safe our local psychiatric system is. Although the risk of becoming victim of crime committed by a mentally ill person is comparably small, it should be a goal to eventually minimize the risk for our patients to hurt themselves or others. Therefore we developed the Bremen Risk Assessment Scale for General Psychiatry (BRAS-GP) to identify high-risk-patients.

Method: We included all in-patients that have been sent to our hospital by involuntary commitment. The BRAS-GP consists of 18 items including questions concerning the case history, psychopathology and social background. During the ongoing 1 year follow-up we plan to validate our checklist.

Results: Between 1.10.-31.12.06 we received 1023 patients in our hospital. 198 (=19%) of these were sent to us by involuntary commitment or received this status during their stay. 29% of these 198 patients were expected to commit severe violent acts in the future. Patients with schizophrenia, personal disorders and addiction were over represented in this pool. A pre-evaluation till September 2007 shows a sensitivity of 0.77.

Conclusion: Assessing violence risk for patients discharged from a general psychiatric hospital is important to find treatment strategies that might help reducing aggression against others and lowering numbers of patients sent to forensic wards. Our risk-checklist is easy to use but needs further investigation to validate and improve it.

OC-13-10
BEING A REFUGEE AND REMEMBERING: HOW, IN WHAT LANGUAGE?

INSTITUTIONS
1. ASM13, Centre Philippe Paumelle, Paris, France

AUTHORS
1. Genevieve Welsh¹, Dr, MD, genevieve.welsh@gmail.com
2. Mei ling Lin¹, Mrs, o.lin@libertysurf.fr

Among patients from South East Asia treated in ASM13, most of them are psychotic depressed or border line Chinese from Cambodia. Some do not speak French even 25 years after arrival, although in families 4 to 5 languages are used. We created a specific consultation with interpreters who speak Cambodian, Vietnamese and Teo Chew. The interpreters are Cambodian, the psychiatric staff is European: the development of the setting raised anthropological and psychoanalytic questions. Most of the patients seemed to have lost their cultural roots after wars, exiles and genocide.

We used to think in terms of post traumatic disorder, impossible mourning and in terms of acculturation. The relation to China was not made explicit during our work in this kind of setting, until a Taiwanese psychologist speaking Mandarin and French was included in the staff. We discovered during the consultations, that many patients could speak Mandarin.

1) They used Mandarin, which is not one of the languages they speak at home
2) They began a process of remembering regarding personal and family memories
3) They mentioned their Chinese ancestors and their filiations

We started group sessions on cultural Chinese celebrations such as New Year, gathering several patients who recalled the way they were celebrated in their homeland. We discovered that the process of remembering was enhanced in the group multilingual situation. We shall give examples of this opening to remembering in individual and in group settings, and propose cultural and psychoanalytic hypotheses on how Mandarin was the only language which could enhance remembering.

Background: SPAID stands for Psychiatric Instrument for the Intellectually Disabled (ID) Adult. It consists in a package of rapid and easy-to-use instruments for the trans-professional assessment of psychiatric disorders.

Aim: The study aimed at evaluating metric properties of the G (General), PDD (Pervasive Developmental Disorders), and P (Psychoses) modules. Through the application of these instruments researchers also gathered important data on the prevalence of psychiatric disorders in the Italian population with ID.

Methods: A sample of around 270 persons with ID was randomly or consecutively recruited to be assessed for concurrent psychiatric disorders through the application of the SPAID-G. For a part of the sample the Italian adaptation of the Matson’s DASH, the Krajer’s PDD-MRS, the SPAID-DPS, and the SPAID-P were also compiled. To reduce limits of the previous studies, characteristics of recruitment centres were further differentiated.

Results: Around 40% of the sample was assessed to have a cluster of psychopathological symptoms that could be consistent with a psychiatric diagnosis. Autism, impulse control disorder, and dramatic personality disorder resulted to be the most frequent over-threshold scores. Correlation of area scores between SPAID and the other instruments still resulted to be higher than 60%. Internal consistency and inter-rater reliability of the SPAID were also confirmed to be high. In respect to DASH researchers found that SPAID could present some advantages: less time consuming, more precise chronological criteria, more syndrome-based severity criteria, consideration of exclusion criteria, higher selectivity for frequency criteria.

INTERNET ADDICTION AND SEVERE MULTIPLE MEDIA ADDICTION - FIRST EXPERIENCES OF AN IN-PATIENT TREATMENT PROGRAM IN BERLIN

INSTITUTIONS
1. Vivantes Netzwerk Berlin, Kliniken für Kinder- und Jugendpsychiatrie, Berlin, Germany

AUTHORS
1. Oliver Bilke

Introduction: Multiple media addiction (“MMa”) seems to emerge as a mental health problem in adolescents. Although not yet broadly recognised by addiction research, there exist clinical and neurobiological implications, that MMa resembles classical adolescent addiction patterns such as marihuana or alcohol.

Method: As part of either the dependency and of the in-patient psychotherapy programs in a large mental hospital covering inner-city Berlin a simple probatory treatment system was established in May 2007. Using mouth to mouth information, presence in media and symposia for experts professional attention was drawn on this topic.

The treatment concept is divided in three phases: absolute abstinence, re-learning prosocial media techniques and multimodal therapy of underlying psychiatric disorder.

Results: For the past half year we could administer seven severe "MMa"-cases with all signs of clinical dependency, both neuropsychological and somatic, including cardiovascular problems, severe craving and pseudo-hallucinations. Five patients could be only administered after massive juridical intervention at home having themselves totally isolated for months playing up to 20 hours a day. 24 other patients were admitted in the same period due to minor forms of "MMa", not establishing an addiction diagnosis due to ICD-10.

Conclusion: There seems to be a small but severely ill subgroup of multiple media users that develop social isolation, craving and other features of addiction. Using the clinical diagnosis MMa offering an in-patient approach and treating them in a three-step-program seem to be a beginning in this field. Obviously intense research is needed in this broadening area.

EFFICIENCY OF SUGGESTIVE METHODS BY TREATMENT OF DEPENDENCES

INSTITUTIONS
1. Private narcological clinic „Varpas”, Psychotherapy, Vilnius, Lithuania

AUTHORS
1. Patricijus Jusaitis, Dr, MD, patricijus.jusaitis@makatukas.net

Within 18 years we have treated 16,260 patients from alcohol or drug addictions by suggestive methods-modified at our clinic method of Ukrainian doctor Dovzhenko combining with emotional-stress catharsis psychotherapy created at our clinic in 1988. From all treated patients 98 % were treated from alcohol addiction and 2 % from drug addiction. 11,8 % were woman, 11,7 % high educated patients, 32,7 % were treated at in or out-patient departments before. 46,2 % were 30-39 years old, 31,1 % over 40 years old, 22,6 % 20-29 years old. Only 0,1 % till 19 years old. At our cathomnestical data remission period spread from 1 to 18 years by 70,4 % of all treated patients (11.750). From this number remission period from 1 to 5 years - 60,8 % of all treated patients (9880 patients), from 5 to 10 years - by 6,4 % (1043 patients), from 10 to 15 years - 2,7 % (441 patients) and over 15 years - 0,5 % (86 patients). Higher than average results were by treatment of women, higher educated patients and, what is very important, by treatment of before compulsory treated patients. Less than average treatment results were by treatment of patients treated before at in-patient departments. Our experience during 18 years confirm that suggestive methods oriented to suppression of inclination to alcohol or drugs are very effective. Our experience from recent years conforms that suggestive methods are effective by treatment of gambles too.

CHARACTERISTICS OF THERAPIST’S COMMUNICATIONS IN GROUP PSYCHOTHERAPY OF PSYCHOTICS

INSTITUTIONS
1. Psychiatric Clinic, Faculty of Medicine, Nis, Serbia and Montenegro

AUTHORS
1. Snezana D Manojlovic1, Dr, PhD, tomas@eunet.yu
2. Julijana M Nikolic-Popovic1, Dr, PhD, lulap@ptt.yu
3. Suzana D Tosic-Golubovic1, Dr, PhD

Group psychotherapy in homogenous groups poses specific requests in front of the therapist. In small group of psychotics therapist becomes a bridge for reconstitution of communication and for restoring and translating the meanings of nonverbal and emotional messages in understandable verbal statements. Therapist’s communications in 5 small groups of paranoids (48 patients) and 5 small groups of schizophrenics (40 patients) are investigated. Communications are measured by Bales’ system of categories. At the beginning of the psychotherapeutic process and after 8 weeks the observer classifies therapist’s communication into 12 categories, grouped into 4 types of communication: emotionally positive, problem solving – answers, problem solving – questions, and emotionally negative. Results indicate the different structure of therapist’s communications in groups of paranoids regarding the groups of schizophrenics.

In the first measurement in the groups of paranoids, the total score of therapist’s communications (38.2%) is significantly higher than in the second measurement (p<0.001). Dominant therapist’s communications are emotionally positive and problem solving - questions. In the groups of schizophrenics both measurements show high percentage of the therapist’s communications, the most frequent are the emotionally positive, and then the problem solving – answers, while in the 2nd measurement the last one decreased in favour of problem solving - questions. Difference of the therapist’s communications is the consequence of the specificity of these two pathological processes, before all, of the specificity of cognitive styles that the therapist meets.

ATTITUDES TOWARDS PSYCHIATRY AND CAREER PERSPECTIVE AMONG SERBIAN MEDICAL STUDENTS

INSTITUTIONS
1. Institute of Psychiatry, Belgrade, Serbia and Montenegro
2. Medical School University of Belgrade, Belgrade, Serbia and Montenegro

AUTHORS
1. Nadja P Maric1, Dr, PhD, nadjamaric@yahoo.com
2. Dragan Stojiljkovic2, Dr
3. Miroslava Jasovic-Gasic1, Prof Dr, PhD

Aim: Better understanding of the attitudes and career perspective of Serbian medical students (MS), with the focus on psychiatry.

Method: MS entering second year of Medical School, University of Belgrade, in 2007 (n=114; 71.9% female, age 20.1±0.7 years, coming from grammar school (62.3%) or medical high school (37.7%)), filled out the 23-item questionnaire(1) modified by authors (N=114 to explore the degree to which MS: (a) consider possible careers among various specialties, (b) find various specialties attractive as careers and the degree to which others respect the skills of physicians in various specialties (internal medicine, surgery, pediatrics, gynecology, general medicine and psychiatry).

Results: Surgery was ranked the highest, followed by internal medicine, pediatrics and psychiatry. Psychiatry was identified as desirable by 35.4% MS. Conversely, 64.6% considered it unlikely that they would choose psychiatry as a career. Only 13.0% MS regarded psychiatry lower than each of three aforementioned specialties in regard to: satisfying job, enjoyable work, prestigious, helpful to patients, interesting subject matter, intellectually challenging, drawing on all aspects of medical training, based on a reliable scientific foundation, expected to have a bright future, and rapidly advancing field of understanding and treatment. On degree to which they, family, classmates and other physicians respected the skills and knowledge, MS rated psychiatrists lower than all other specialists, except general medicine.

Conclusion: Some negative attitudes may be corrected and should be actively targeted within the medical school curriculum.
OC-14-06
SEVERAL ISSUES ON APPLICATION OF INTERVISION METHODS IN PSYCHOTHERAPEUTIC GROUPS

INSTITUTIONS
1. Association of psychotherapists in Azerbaijan, Baku, Azerbaijan

AUTHORS
1. Tofik Najafov1, tofikdacha@rambler.ru

The widespread definition of intervision is conduction of a therapists’ group for the purpose of anxiety reduction, determination of the professional boundaries and personal development. The aim of our research has been further development of the intervision definition by utilizing the second circle of therapists not only for the above-mentioned purposes. The therapists were considered as active members of the group process and they were enabled by additional capacities such as:
- Limited capacity for intervisors to make remarks, commenting in the process of the group conduction
- After-group discussions between facilitators and intervisors upon the group

Discussions between facilitators and intervisors upon the group conduction at the presence of the group members Quality assessment has been made on effectiveness of the utilized method in the groups with intervision and the control groups. The tools of assessment were:
- Comparative analysis of group development
- Comparative analysis of drop-out rates
- Comparative analysis on range of the worked-out issues

The studies on the groups revealed the following results for the groups with intervision in comparison with control groups:
- Range of worked-out issues was bigger
- Group development was more dynamic
- Lower drop-out rates

In addition to the abovementioned advantages, it should be noted that application of the method promotes more intensive education of the therapists, building-up team thinking and creation of “realistic” perception of a therapist image in the group.

PSYCHOPATHOLOGICAL IMPACT OF CHILDREN’S AND ADOLESCENTS’ EXPOSURE TO VIOLENT IMAGES

INSTITUTIONS
1. Private practice, Greece

AUTHORS
1. Vasileios Thermos1, Dr. M.D., Ph.D., thermosv@otenet.gr

Both post-modern focus on the subjective excitement of experience and the contemporary pervasive children’s and adolescents’ access to violent TV and Web images, seem to increase their susceptibility to violence in the western world. Nowadays violent images are abundant and unmediated, and with decreasing parental ability for control and barriers. Exposure to them since a quite early age may, in combination with certain social pathologies, result to an escalation of individual violent behaviors, especially when identity issues are at stake, and the capacity for sublimation is poor. In terms of transition to adult psychopathology, we have been witnessing (and further expect) an increase of borderline personality disorders, and of psychotic and pervasive psychic structures. Kleinian, Winnicottian, and Lacanian ideas are utilized to compose a psychoanalytic critique of children’s and adolescents’ perception and metabolization of violence. Questions about the need for revisioning cultural attitudes and promoting mental health prevention policy are posed.
PERSONALITY DISORDERS PREDICT RELAPSE IN MAJOR DEPRESSION: 6-YEAR PROSPECTIVE STUDY

4. John G Gunderson\textsuperscript{3}
5. Les C Morey\textsuperscript{4}
6. M T Shea\textsuperscript{5}

Objective: To examine prospectively the natural course of major depressive disorder (MDD) and to test for the moderating effects of personality disorder (PD) co-morbidity on relapse after remission from an episode of MDD.

Methods: Participants were 303 patients with current MDD at baseline in the Collaborative Longitudinal Personality Disorders Study, an ongoing NIMH-funded multi-site prospective multi-wave study. Patients were reliably assessed using semi-structured diagnostic interviews. MDD and psychiatric disorders were assessed with the Structured Clinical Interview for DSM-IV and PDs were assessed with the Diagnostic Interview for DSM-IV PD. The course of MDD was assessed with the Longitudinal Interval Follow-up Evaluation at 6- and 12-months and then yearly through 6 years. Survival analyses were used to analyze time to remission and time to relapse, with the Kaplan and Meier method to estimate cumulative rates.

Results: 260 of 303 patients had a remission from MDD; lifetable survival analyses revealed that MDD patients with PDs had significantly longer time to remission from MDD than patients without PDs (log-rank chi-square=14.95, p<0.0001). Among the 260 patients with a remission from MDD, those with PDs had significantly shorter time to relapse (log-rank chi-square = 5.31, p=0.02). Overall multivariate prediction of relapse (Cox proportional hazards regression analyses) revealed presence of PDs (hazard ratio 1.5) and recurrent-type MDD (hazard ratio 2.2), but not dysthymia (hazard ratio 0.97) significantly predicted time to relapse.

Conclusion: PDs were robust predictors of accelerated relapse after remission from an episode of MDD.
EMOTION PROCESSING IN SCHIZOPHRENIA: IMPACT ON SOCIAL FUNCTIONING AND REHABILITATION STRATEGIES

Institutions
1. University of Porto: Faculty of Psychology and Educational Sciences, Portugal
2. Higher Polytechnic Institute of Gaia: School of Social and Community Development, Portugal
3. Porto Polytechnic Institute: School of Allied Health Science, Portugal

Authors

2. Cristina Queirós
3. Nuno Rocha

Persons with Schizophrenia display a wide range of impairments in social functioning, in part due to difficulties understanding other’s intentions and emotional states. In this presentation we will focus on deficits in emotion perception, based on studies carried out recently with Portuguese schizophrenic patients and in research review. Emotion recognition deficits have been consistently demonstrated as well as their relationship with poor social function, although further research is needed to clarify this issue. Empirical findings also have shown that rehabilitation strategies may have positive effects in what regards improvement of emotional processing skills, but few studies analyzed the clinical impact of such interventions on community functioning. This is a promising area needing further research.

FACTORS ASSOCIATED WITH THE RISK OF READMISSION TO AN ACUTE PSYCHIATRIC INPATIENT FACILITY: A RETROSPECTIVE COHORT STUDY

Institutions
1. Melbourne Health, NWAMHS, Melbourne, Australia
2. University of Melbourne, Psychosocial Research Centre, Melbourne, Australia

Authors
1. Jianyi Zhang, Dr, FRANZCP, jiamyi@bigpond.com.au
2. Carol A Harvey, Associate Professor, MD, c.harvey@unimelb.edu.au
3. Carol M Andrew, Ms, RPN, carol.andrew@mh.org.au

Aims: This study aimed to investigate the predictors for the risk of readmission to an acute psychiatric inpatient unit.

Methods: A retrospective cohort study was embedded in a cross-sectional clinical file audit of 178 randomly selected patients who had at least one admission during a twelve-month study period. All patients were retrospectively followed up for at least 12 months. A total of 286 variables were collected and analysed.

Results: Eighty-two patients (46 percent) were readmitted during the follow-up period. Cox regression analyses showed 9 variables were related to the risk of readmission. Six of these variables increased the risk of readmission. They included the number of previous admissions, risk to others at the time of index admission, contact with emergency department post-discharge, alcohol intoxication and ECT treatment. More active and assertive treatment in the community post-discharge decreased the risk of readmission, eg, involuntary treatment, reviewing the individual service plan and transferring to a new treating team. Patients’ socio-demographic characteristics, a diagnosis of a major psychiatric illness, length of previous admission or index admission, or the clinical practice and care provided at the inpatient unit did not influence the risk of readmission.

Conclusions: A sub-population of patients who require frequent psychiatric admission is identifiable. Quality of inpatient care does not influence the risk of readmission, which therefore raises a question about the validity of using the rate of readmission as an outcome measure of psychiatric inpatient care. Good psychiatric practice within the community following discharge likely reduces the risk of readmission.
OC-15-03
AN ALTERNATIVE APPROACH TO TREATMENT OF DEPRESSION

INSTITUTIONS
1. Independent Private Practice, New York, United States

AUTHORS
1. Yukio Ishizuka1, Dr., MD, dri@lifetrack.com

Objective: To demonstrate through 3 case examples (1. acute suicidal depression, 2. chronic depression, and 3. treatment-resistant depression) that depression can be predictably overcome by personality transformation through 'breakthrough intimacy' - closeness between committed couples far beyond their previous maximum experiences - without medications, and often within 6 months.

Method: Working with the patient and his/her partner in three-way teamwork, therapist actively help the patient couples to think, feel, and act in such ways that their closeness will increase beyond their previous maximum experience, provoking and overcoming waves of spikes of depression, until it disappears by exhaustion, guided by their own daily self-rating on 41 parameters that allow accurate graphic tracking of subtle changes in their personalities and dynamic mental status.

Results: Of the 1,170 patients (nearly all of them showing varying degree of depression) treated over the last 20 years, 48% reached a level of adjustment higher than their previous maximum level beyond symptom elimination. Among them, 31% reached a level up to twice, 24% reached up to three times, 20% reached up to four times, 16% reached up to five times, and 7.6% reached up to and beyond 10 times their previous maximum level according to their own daily self-rating. Of those who failed to reach their previous maximum level of adjustment before termination, 75% showed significant improvement in overall adjustment and 77% showed reduction of symptoms.

Conclusion: Depression may be better understood and treated as consequence of one's personality, which can be transformed through 'breakthrough intimacy.'

DYSFUNCTIONAL ATTITUDES, SOCIAL SUPPORT AND QUALITY OF LIFE OF SCHIZOPHRENIC AND BIPOLAR PATIENTS IN REMISSION

INSTITUTIONS
1. University of Mohaghegh Ardebili, Iran (Islamic Republic of)

AUTHORS
1. Usha Barahmand1, Dr., PhD, usha.barahmand@gmail.com
2. Sommaiye Jalilzadeh1, Ms.
3. Khadijah Aziminia1

The prognosis of psychotic patients in remission is often associated with the social support and the quality of life they enjoy. Furthermore, it is well-established that the presence of dysfunctional cognitions indicates a vulnerability to psychopathology and bears strong relationships with psychological distress.

Aim: The purpose of the present study was to compare the dysfunctional attitudes, social support and quality of life of recovering schizophrenic and bipolar patients.

Method: A sample of 30 schizophrenic and 30 bipolar patients who had been symptom free for 18 months were recruited for the study. The two groups did not differ in terms of mean age, education, income and marital status. The Dysfunctional Attitudes Scale, Social Support Appraisals Scale and the WHO Quality of Life Scale were administered.

Results: Findings revealed that the two clinical groups did not differ in terms of dysfunctional attitudes, social support and quality of life. However, while quality of life in the schizophrenic group was not associated with social support or dysfunctional attitudes, in the bipolar group, quality of life correlated positively with social support and negatively with dysfunctional attitudes. Furthermore, sex differences emerged only in the schizophrenic group, with recovered female schizophrenics reporting significantly more dysfunctional attitudes and less social support. Multiple regression analysis indicated that in the schizophrenic group, neither dysfunctional attitudes nor social support was predictive of quality of life, while in the bipolar group, dysfunctional attitudes and social support accounted for 16.2% and 15% of the variance in quality of life respectively.

Aims: We aimed to identify, in the general population of adolescents, whether a questionnaire psychopathology assessment could predict the onset of psychosis.

Methods: Members (n= 9,215) of the northern Finland 1986 Birth Cohort, an unselected general population cohort (1), were invited to participate in a field survey during 2001, at ages of 15-16 years. The study included a 21-item prod-screen questionnaire screening prodromal symptoms of schizophrenia for the previous six months (2). Prod-screen included nine questions for positive and five questions for negative symptoms. The Finnish Hospital Discharge Register was used to identify new cases of hospital treated mental disorders during 2002-2005.

Results: Of the subjects 0.3% were treated for first episode psychosis and 1.5% for non-psychotic disorder during the follow-up period, ages 16-19 years. Positive symptoms did not associate with the onset of psychosis, but negative symptoms did. Negative symptoms were reported by 94% of the later psychotic subjects, by 48% of those hospitalized for non-psychotic disorder and by 46% of the ‘healthy’, without psychiatric hospital treatment (Fisher’s exact test: psychosis vs. healthy p<0.001, psychosis vs. non-psychosis p<0.001, and non-psychosis vs. healthy p=0.61).

Conclusions: The findings emphasize the importance of negative symptoms in the development of first episode psychosis.

We present the case of three identical male triplets who have been suffering from schizophrenia. The three men, who had similar pre-morbid manifestations, namely obsessiveness and perfectionism along with a symbiotic pattern of co-existence, developed almost identical psychosis at least 4 years before their eventual admission for impatient treatment at the age of 23. Their psychopathology comprised trichotillomania in the context of an elaborate pseudo-philosophical world view that led them to grandiose self-perception, withdrawal, isolation, decline in every aspect of functioning and, finally, physical aggressiveness. Response to antipsychotic drug treatment has not been dramatic for any of our cases, but psychotherapeutic intervention has proved to be meaningful. We argue for an endogenous psychosis in all our three patients, rather than for folie a trois, on the ground that the course of their illness has not proven any one of the three to be dominant over the others, not even after their virtual separation. All three men also have G6PD deficiency and Gilbert syndrome.

The presence of psychotic symptoms in non-psychiatric population may identify individuals at risk of psychosis. The aim of our study was to determine lifetime and current prevalence of psychotic symptoms in the general population of the Czech Republic. Study subjects were selected from a stratified population sample. All participants were administered the Psychosis Screening Questionnaire; in addition, the data on psychiatric treatment and diagnosis according to the M.I.N.I. were recorded. In total, 3244 subjects responded (48.1% males and 51.9% females). The most frequently reported symptom was paranoia (7.7%), followed by hypomania (6.2%), strange experiences (5.2%), thought insertion (3.8%), and hallucinations (1.7%). Lifetime prevalence of at least 1 psychotic symptom was 17.9%. Majority of responders reported only single symptom (13.5% of all participants). Significantly more males than females experienced paranoia (lifetime p=0.002). In the subset of individuals with at least one psychotic symptom, 70.6% never visited a psychiatrist, 78.9% did not meet diagnostic criteria of psychotic disorder according to the M.I.N.I., and 67.0% failed to have any psychiatric diagnosis at all. The results suggest a high frequency of psychotic experience among the ethnically homogeneous Czech population. Cross-sectional study cannot reliably confirm whether the symptomatic subjects are at risk of development of psychotic disorder. However, our findings support a hypothesis of the presence of psychiatric symptoms in the general population as a continuum of psychotic spectrum, from normality and sanity through unique psychotic experiences to fully expressed illness.

Supported by the research project CNS 1M0517.
Delusional parasitosis (DP, known also as Ekbom syndrome) is a neuropsychiatric syndrome in which the patient has the fixed delusion of infestation by parasites. It is a rare condition often associated with early dementia. Interferon induced psychosis has typically an acute onset and resolves after discontinuation of interferon with or without antipsychotic medication. There are few cases of interferon induced persistent psychosis, most of them with a paranoid content. To our knowledge, there are no reports of delusional parasitosis associated with interferon treatment for hepatitis C.

Objectives: to describe a case of DP associated with interferon treatment which may play a role in selecting liver transplant candidates.

Methods: We are presenting a case of DP associated with interferon treatment in a patient who was evaluated as a liver transplant candidate followed by a review of the literature on DP and interferon induced psychosis.

Results: a 55 year old man with remote history of polysubstance abuse in remission for years, with mild intermittent depressive symptoms, started developing delusions of infestation and tactile hallucinations six months after starting interferon treatment for hepatitis C. Medical workup for new onset psychosis was negative. His psychosis led to significant behavioral changes, including hypervigilence and changing physicians frequently. After a brief response to Risperidone, symptoms resumed and persisted after nine months of treatment, despite discontinuation of interferon. His symptoms interfere with his ability to participate in transplant preparation.

Conclusion: DP can be expected when evaluating liver transplant candidates and may interfere with final eligibility for transplantation.

Most epidemiological studies around the world indicate that a close link exists between psychiatric symptomatology and socio-economic variables, with the poorest individuals being the most vulnerable. In 2002, Statistics Canada conducted the Canadian Community Health Survey, Cycle 1.2: Mental Health and Well-Being.

Objective: This study presents a comparison of the level of psychological distress between low-income and non low-income populations in Canada. It describes the predictors of distress identified for each population and presents the differences found with the models used in predicting distress.

Methods: Data were collected through a national survey including 36,984 individuals aged 15 or over in Canada. Of this sample, 17.9% (N=7,940) was identified as being within the low-income population using the low-income measure. Psychological distress was measured with the K-10.

Results: Hierarchical linear regression was employed to construct multivariable predictive models for psychological distress. In the low-income population, the percentage of high psychological distress was as high as 28%, compared to 19% in the non low-income population. Distress levels found among poor individuals surpassed those of more affluent individuals across most of the socio-demographic subgroups including age, gender, marital status, education level, ethnicity/race and first language. Different models to predict distress were identified for low and non-low income populations, which explained respectively 28% and 25% of the variance of psychological distress within these populations.

Conclusion: Variables related to social support, stress and coping abilities were the stronger sets of variables related to distress in both populations.

3. Dartiu X da Silveira1, Dr, PhD, dartiu@psiquiatria.epm.br

Introduction: According to previous research, physicians present higher prevalence of psychiatry disorders when compared to general population. In our country, nevertheless, scientific studies focusing the problem are still lacking.

Objective: To evaluate the performance of internal medicine physicians on screening instruments for psychiatry disorders.

Method: A hundred physicians of clinical areas were selected in a public hospital of São Paulo, Brazil. All of them were asked to answer a questionnaire that included validated screening instruments validated. 83% completed the research protocol properly.

Results: The first part of Self Report Questionnaire aims to evaluate the presence of mental disorders and the average score of the physicians was 2.60 ± 2.44. Taking 7/8 as cut-off, 3.6% of them had higher risk of presenting a psychiatry diagnosis. Depression prevalence was evaluated through the Center for Epidemiologic Studies - Depression scale. The average score was 11.66 ± 26.75. Using 15/16 as cut-off, 10.8% of clinical practitioners scored positively for depressive symptoms. In the IDATE, an instrument for anxiety disorders screening, the average score was 23.39 ± 5.09. 60.2% of the studied population could be considered at higher risk for presenting anxiety disorders (cut-off 21/22).

Conclusion: Compared to Brazilian general population, the frequency of mental disorders was lower among clinicians. The finding concerning depressive symptoms was similar to that found in most scientific research. The most important data, however, concerns the rates of anxiety symptoms, which frequency was much higher among physicians than in general population (prevalence ranging from 7.0 to 18.0%).

Introduction: Clinical studies indicate that depression or depressive symptomatology (DS) are associated with dementia, however, their temporal relationships are controversial. Our study aimed to explore whether DS is predictive of incident dementia in the elderly.

Methods: Longitudinal analysis in a survey of 9294 non-demented non-institutionalized elderly, aged 65 years and over, in 3 French cities. We performed logistic regression analyses of the relation between the level of DS assessed by the Center for Epidemiological Studies Depression (CES-D) scale, at baseline and at 2-year follow-up, and the incidence of dementia at 4-year follow-up, adjusting for sex, age, education, hypertension, history of cardiovascular events, Apo E genotype, the Mini-Mental State Examination score at baseline, and use of antidepressant agents.

Results: Our working sample had a mean age (SD) of 73.7 (5.0) years, included 60.7% of women and 12% of subjects with high level of DS at baseline. The incident rate of dementia was 3%. A high level of DS at baseline increased risk of dementia 4 years later (adjusted OR CES-D high vs CES-D low 1.6, 95% CI 1.1-2.4). The risk of dementia increased with decreasing mean interval between its occurrence and the last time high level of DS was achieved, and with recurrence of high level of DS over the period of follow-up.

Conclusions: We found a close temporal association between DS and increased risk of dementia in elderly subjects. DS seems to be less a risk factor for than a prodromal state of dementia. Jorm A. Aust N Z J Psychiatry, 2001; 35:776-781

Objective: Depression is associated with cardiovascular morbidity but studies on the relationship between depression and blood pressure show inconsistent results. We examined this relationship in a large sample of non-institutionalized elderly people.

Methods: Cross sectional community-based study in 9294 subjects aged 65 years and over [mean age (± SD) 73.7 ± 5.0 years], in 3 French cities. Subjects were categorized as depressive on the basis of self-reported history of treated depression, current depressive symptoms and current or past major depressive episodes using the French versions of the Center for epidemiological studies depression scale, and of the Mini International Neuropsychiatric Interview respectively. Multiple linear regression analyses of the relation between depression and mean systolic (SBP) and diastolic blood pressure (DBP) values were conducted, taking into account potential confounders like age, sex, education, smoking, alcohol consumption, body mass index, cardiovascular history, and antihypertensive or psychotropic agents use.

Results: Overall, 2479 participants met the criteria of depression, 7205 (77.5%) were hypertensive, and 4596 (49.5%) were on antihypertensive drugs. Analyses showed lower mean SBP and DBP values in depressive individuals compared to non-depressive ones, in both men (SBP: 148.2 mm Hg vs 151.8 mm Hg, \(P<0.002\); DBP: 83.0 mm Hg vs 84.7 mm Hg, \(P=0.003\)) and women (SBP: 141.7 mm Hg vs 144.7 mm Hg, \(P<0.0001\); DBP: 80.7 mm Hg vs 81.4 mm Hg, \(P<0.02\)).

Conclusion: Given the high prevalence of depression among elderly people, these results highlight the need of further exploration of pathophysiological mechanisms that could underlie blood pressure-depression association.

6. Ashkhen N. Poghosyan, Mrs

Background: The burden from the loss in developing countries, caused by mental health problems is nearly as big, as in industrial countries, but the majority of such population is not revealed in low-income countries.

Aims: The main objective is to compare some social-psychological peculiarities in inpatients of a specialized psychiatric hospital and outpatients of a primary health care setting, and develop appropriate models of specialized care.

Methods: We work out appropriate documents to collect the clinical-epidemiological data to carry out comparative analysis of two groups of patients: the first group was named “psychiatric” (148 patients), and the second one-“diagnostic” (122 patients).

Results: There were found out significant differences between 2 groups. The number of patients from incomplete families was considerably higher among the “psychiatric patients” - 20.95% vs. 9.84%, and less “psychiatric patients” had grown up in enlarged families - 16.2% vs. 31.2%. There were considerably more families in the “psychiatric” group, where the interrelations between the parents were strained - 26.4% vs. 11.5%. The 24.3% of “psychiatric patients” were living in unsatisfactory housing conditions, and only 1.7% of “diagnostic patients” had the conditions. There were employed 16.22% of “psychiatric patients” and 31.2% of “diagnostic patients”. The rate of exposure to stresses is nearly the same in 2 groups, but the “psychiatric” patients were 3 times more experienced unusual stress events - 29.4% vs. 10%.

Conclusions: The detected difference between different medical centers allows concluding about the role of some social-psychological factors in the formation of psychiatric (mainly depressive) disorders.

OC-16-06
PREVALENCE OF MENTAL DISORDERS AMONG RECRUITS IN ARMENIA

INSTITUTIONS
1. Yerevan State Medical University after M. Heratsi, Department of Psychiatry, Yerevan, Armenia

AUTHORS
1. Armen Eduard Melik-Pashayan, Dr, MD, PhD, armelikpashayan@yahoo.com

Objective: The study of mental health of recruits is one of the main factors of preventing of extreme situation in army. The clinical and epidemiological research works of recruits mental health in literature are not many. Up today there is no concrete diagnostic criteria which can help psysican to understand if the recruit can serve in the army or not. The aim of research work is to study the epidemiological aspects of mental disorders of recruits in Armenia, the correlations of those disorders with the age of patients and their living region (city, village).

Methods: We studied 3169 recruits (age 16-28) during 6 years, who were sent to pass psychiatric expert commission.

Results: Basically the recruits were at the age of 18-28 (88.8 %), 10.9% were at the age of 16-17 and only 0.3% were older than 28. 66.0% recruits were from villages and only 34% from cites. We deli-ver the mental disorders into the following groups: mental retardation, psychoses, non-psychotic mental disorders. From recruits that were observed in ambulatory, in stationary 39.6% their psychiatric symptoms were reviewed and these people were known as mentally healthy. The mental retardation occurred in 39.5% during six years, the same results in literature data. Psychoses were in 0.2%.

Conclusion: Because of divergences in diagnoses of mental disorders among recruits in different levels of expertision (ambulatory and stationary), so it makes sense to hold regularly licensing of the expert-doctors, and to guarantee continuity in diagnostic approaches, hold their rotations

PREVALENCE OF MENTAL DISORDERS AMONG PEOPLE LIVING IN HOUSEHOLDS IN DURBAN, KWAZULU-NATAL, SOUTH AFRICA

INSTITUTIONS
1. UNIVERSITY OF KWAZULU-NATAL, PSYCHIATRY, DURBAN, South Africa

AUTHORS
1. Dan L. Mkize, PROFESSOR, mkizedl@ukzn.ac.za

Introduction
For the purpose of planning mental health services and the training of mental health personnel, it is crucial to have sound information about the prevalence of mental disorders in the population and the use of mental health services in the community. The epidemiological approach is necessary for assessing the prevalence of mental disorders in specified population groups. This type of approach is of special importance in those areas whose mental health services are not fully developed.

Aim of the study: This was a household survey to determine the prevalence of mental disorders amongst people living in households in Durban, Kwazulu-Natal, South Africa, using structured interviews.

Objectives: To administer four questionnaires, the Demographic Characteristic Questionnaire (DCQ) the 20 item Self Report Questionnaire (SRQ 20), the Reporting Questionnaire for Children (RQC) and the Mini International Neuropsychiatric Interview (MINI) to selected individuals in households in and around Durban. To compare the prevalence rates according to age, gender, race and grade. Methodology: EThekwini was divided into five clusters. 1 000 households were randomly selected from each cluster giving a total of 5 000 households. Sampling of respondents was by the Kish method of sampling. Those who scored above a cut-off point in the SRQ and RQC were further interviewed using the MINI.

Results and Conclusion: This study is not yet completed. The results of the study will be discussed at the conference.

A SURVEY OF PERSONS WITH MENTAL ILLNESSES WITH YOUNG CHILDREN WHO ARE LIVING IN THE COMMUNITY

INSTITUTIONS
1. Institute of Mental Health, Medical Social Work, Singapore, Singapore
2. Institute of Mental Health, Community Psychiatry, Singapore, Singapore

AUTHORS
1. Weng Cheong Poon, Mr, MSW, BA, weng_cheong_poon@imh.com.sg
2. Cheng Lee, Dr, MBBS, MMED, FAMS, cheng_lee@imh.com.sg
3. Lilian Mark, MS, BA, lilian_le_mark@imh.com.sg

A needs analysis survey of persons with mental illness (PMI) who are living in the community and have young children in Singapore was conducted. The aim was to identify the percentage of this client group and to identify the needs and service gaps. Currently, there are insufficient services in Singapore addressing the needs of PMI with young children. There was no statistics to show the percentage of this client group locally. From overseas studies, 20-30% of PMI had young children and female clients had more contact with young children. The hypotheses were to determine the above two findings.

The study was conducted over two weeks at three psychiatric outpatient clinics. Patients were screened using a questionnaire to determine whether they have young children who are below 18 years old. If patients had young children, they were asked to fill up a minimum data set to understand their social-economic background. Patients were then invited to participate in a needs survey. A total of 2314 patients were screened over two weeks. 33.4% of cases were parents. Out of those who were parents, 65.5% of them were female and 30.5% had young children. Moreover, 58.1% of those who had young children were female. In addition, social-demographic profile of patients with young children was also recorded. The survey was strategic to identify the percentage of PMI with young children. The results of the study suggested the need to develop services and policy for PMI with young children and additional customised services for female parents.

Objectives: to estimate the prevalence of alcohol and tobacco use in slum dwellers. to explore substance-use related domestic violence.

Methods: Community based survey; random systematic sampling design of 327 houses holds with Sample size of 723 subjects

Questionnaires:
A. Substance use/abuse questionnaire: Questionnaire used was pre-coded and structured proforma, used in large studies of assessment of alcohol/substance use by India Council of Medical Research
B. Domestic Violence Questionnaire: It is an 18-item questionnaire developed by experts at the psychiatry department which is pre-tested. Face & content validity judged to be satisfactory.

Results: Of 723, 56.7% were males; majority (26.0%) was of 35 to 44 yr. age group and 85% were married. About 90% had ‘ever used’ substance, whereas around 80% had used in ‘last month’. Tobacco (80%) and alcohol (27%) were most common substances 77% and 60% subjects used tobacco and alcohol respectively, daily. Among last month alcohol abusers (n=525), 58% had socio-occupational dysfunction, craving 26.8%, and lack of control 56%. About 16% wives experienced violence, perpetrated by their husband (65%) during substance abuse. Separation was less (6%). About 20% children also became the victim.

Conclusion: Alcohol and tobacco use/abuse was common. Substance use related domestic violence was perpetrated by husband to their wives, which is consistent with the finding that the most common type of violence against women is “domestic violence” from their partner¹

MAINTENANCE AND CONTINUATION ECT

INSTITUTIONS
1. Santa Maria Hospital, Psychiatry Department, ECT Unit, Lisbon, Portugal

AUTHORS
1. Ricardo Coentre1, Dr., MD, Ricardo.Coentre@netc.pt
2. Daniel Barrocas1, Dr., MD
3. Manuela Abreu1, Dr., MD
4. Jorge Maltez1, Dr., MD
5. Pedro Levy1, Dr., MD

Aim: Electroconvulsive therapy (ECT) is in general discontinued after a favourable course of sessions, when remission of the initial symptoms occurs. The majority of psychiatric disorders are chronic and recurrent, the rational of extending ECT is supported by the lower rates of recurrence and relapse seen with continuation (<6 months) and maintenance (>6 months) ECT.

Methods: The authors made a review of the literature in Medline, PubMed and published guidelines. Forty two articles were found and 36 were selected.

Results: The evidence is composed by case reports, retrospective studies and few prospective studies, it is necessary more randomized and controlled studies focusing on this type of ECT treatment. Continuation and maintenance ECT is little mentioned in the published guidelines, although several studies show that it is efficient, safe, well tolerated and has a low cost-benefit ratio. This treatment reduces the recurrence, relapse and re-hospitalization of patients who had a first initial course of ECT with good improvement. The number and time of the sessions should be scheduled according to individual treatment response. The cognitive effects of maintenance and continuation ECT are similar or even lesser than those reported with only one course of ECT in the acute phase of the disease.

Conclusions: Continuation and maintenance ECT should be considered when remission of the mental disorder could not be achieve with another treatment and if the patient had a favourable response to an initial series of ECT.

ELECTROCONVULSIVE THERAPY IN AUTISM: HOPE FOR SEVERE PSYCHOPATHOLOGY

INSTITUTIONS
1. Kennedy Krieger Institute/Johns Hopkins Hospital, Psychiatry, Baltimore, United States

AUTHORS
1. Lee E Wachtel1, Dr., MD, wachtel@kennedykrieger.org

Aim: This paper reviews electroconvulsive therapy (ECT) in children and adults with autism and concomitant psychopathology, including affective illness, catatonia and self-injury. Case examples are highlighted.

Method: A review of the English-language literature on ECT in pediatric, adult, autistic and mentally retarded populations was conducted, with focus on catatonia, drug-resistant psychiatric illness and self-injury. This was combined with the author’s experience with two autistic adolescents in catatonic stupor, and an autistic child and young adult with severe affective disturbance and self-injury. All four patients underwent ECT with excellent symptom resolution.

Conclusion: Electroconvulsive therapy affords excellent symptom remission in autistic individuals with affective illnesses and catatonia, which may be complicated by dangerous self-injury. Prompt diagnosis and pursuit of ECT significantly improve clinical outcome in this patient population.

Aims: Magnetic seizure therapy (MST) is a new treatment for depressive disorders which aims to produce the treatment effects of ECT, but with fewer cognitive side effects. Seizures are elicited with a high-frequency magnetic field over the head of the patient.

Methods: We have performed a pilot study of a new magnetic stimulator (Magstim Theta) capable of delivering magnetic pulses at 100Hz frequency to elicit therapeutic seizures. We have tested the capability of the device to elicit seizures in 11 patients with one to five stimulations of between 250 and 1000 pulses given at 100Hz or 80Hz.

Results: Seizures were elicited in ten of the eleven patients. The mean duration of magnetically induced seizures was 31.3 sec, ranging from 10-86 sec. All patients had an exceptionally quick recovery of orientation, on average 16min 44sec shorter with MST than with ECT in the same patients (paired-samples t-test: p=8x10^-5). Patients reported feeling less confused after MST. Side effects were confined to myoclonic movements, associated with the use of etomidate.

Conclusion: The new 100Hz magnetic stimulator elicits seizures in most patients when administered over the vertex. The stimulation parameters of MST have to be optimised further, and different coil configurations are likely to prove more efficient. The four centres have started trials to assess the effectiveness of MST and compare the cognitive side effects of ECT and MST.

4. G. Byrne

Background: Huntington's disease (HD) is an autosomal, dominant neurodegenerative disorder characterized by cognitive decline, personality change, motor impairments, and increased susceptibility to mental disorders.

Aims: The main purpose of this study was to determine if neuropsychological deficits could be identified in HD carriers and to examine the potential selectivity of presymptomatic cognitive impairment in HD.

Methods: A broad neuropsychological assessment battery including WAIS-R was administered to 64 participants in the predictive testing program. No participants displayed neurological or psychiatric signs of HD. All subjects were tested individually and the tasks were administered prior to molecular analysis of carrier status (30 gene carriers and 34 noncarriers). The mean predicted age of onset was calculated by a regression equation based on CAG repeat information to 15 years.

Results: When the carrier group was divided based on predicted years to onset (HD+ ≤15 and HD+ >15) the HD+ ≤15 group had significantly lower scores in Verbal, Performance, and Total IQ compared to noncarriers. The carriers evinced significantly worse performance in six of the 11 subtests of the WAIS-R. The remaining tasks revealed group differences also favouring noncarriers. The impaired cognitive functioning revealed primary deficits in language abilities, attention, abstract thinking, problem solving, visuospatial ability, and psychomotor speed.

Conclusions: Deficits in executive functions, such as reasoning, attention, abstract thinking and psychomotor speed are early preclinical signs of HD. These impairments affect general intelligence and functioning of HD asymptomatic carriers and reflect dysfunction of frontal cortex and fronto-striatal circuits.

Aims/Objectives: An increasing number of treatment studies focus on impaired cognition and emotion processing in schizophrenia. Imaging studies suggest the presence of dysfunctions in prefrontal-temporolimbic circuits. We evaluated neuronal activation with functional MRI and auditory event-related brain potential (ERP) in schizophrenia patients treated with atypical antipsychotics. The study was carried out in order to evaluate whether combinations of new antipsychotics with a specific cognitive training program was more effective than atypical antipsychotics alone.

Methods: Patients were examined by fMRI at baseline and after 8 weeks of treatment with atypical antipsychotics. In the scanner stimuli were presented in a 2-back and 0-back condition of a working memory paradigm. To investigate the neurophysiological changes ERP components N1, P2, P300 were recorded before and after treatment from 19 EEG leads in a two-tone oddball paradigm. Schizophrenic patients (n=10) were compared with a randomized group of patients in the cognitive training (n=10).

Results: Treatment with new antipsychotics was associated with significant increase of activation in the right dorsolateral and left ventrolateral prefrontal cortex (p<0.001 uncorrected) and with an increase of P300-amplitudes and higher P2/N2 differentiation. The cognition training group revealed significant improvements in cognitive functions and transfer effects in skills needed for daily life.

Conclusions: New antipsychotics may improve the functionality of the networks needed for partial storage and processing of information. Cognitive training in combination with new antipsychotics, are important treatment techniques for improving social functioning relevant for rehabilitation.

CSF TAU PROTEIN IN THE DIFFERENTIAL DIAGNOSIS OF GERIATRIC DEPRESSION AND MILD COGNITIVE IMPAIRMENT

INSTITUTIONS
1. University of Leipzig, Psychiatry, Germany
2. University of Heidelberg, Psychiatry, Germany

AUTHORS
1. Peter Schoenknecht¹
2. Elmar Kaiser²
3. Johannes Schroeder²

Objective: In Alzheimer’s disease (AD), an accelerated neurofibrillary tangle formation is associated with increased tau protein release into the cerebrospinal fluid (CSF). Significantly increased CSF tau protein levels were found in patients at risk to develop AD indicating its potential as an early marker. Though mild cognitive impairment in preclinical AD often overlaps with depressive symptoms making early diagnosis difficult, to date no CSF marker has been probed to support the differential diagnosis of geriatric major depressive disorder and mild cognitive impairment eventually converting to AD. Methods: 81 patients with mild cognitive impairment (ageing-associated cognitive decline criteria), 54 patients with geriatric major depressive disorder and 27 cognitively healthy controls were included. In all participants, CSF levels of tau protein were determined by ELISA at baseline. All patients were re-assessed clinically after a follow-up period of at least 12 month.

Results: During follow-up, 29% of the patients with mild cognitive impairment but only one patient with geriatric major depressive disorder converted to AD. CSF tau protein levels at baseline distinguished significantly between mild cognitive impairment, geriatric major depressive disorder and controls. Already at baseline converters to AD were characterized by significantly higher tau protein levels compared to any of the other diagnostic groups. Conclusion: CSF tau protein levels distinguish geriatric major depressive disorder from preclinical AD and may predict conversion to AD in the course of disease.
DOWNREGULATION OF CAMP/PKA PATHWAY AND DARPP-32 EXPRESSION IN PC12 CELLS OVEREXPRESSING NCS-1 IS INDEPENDENT OF DOPAMINE RECEPTORS

DARPP-32 and neuronal calcium sensor-1 (NCS-1) are two proteins involved in dopaminergic signaling. DARPP-32 plays a central role in dopaminergic signaling and NCS-1 modulates desensitization of D2 dopamine receptors and enhances neurotransmitters release. It was reported that NCS-1 colocalizes with D2 dopamine receptor in both pyramidal neurons and interneurons in the primate prefrontal cortex (PFC). Recent articles have reported an increase of NCS-1 levels and decrease of DARPP-32 levels in PFC of both bipolar disorder and schizophrenic subjects. It is well known the involvement of dopamine in these psychiatric disorders, so, in this study, we have addressed whether increased levels of NCS-1 could reflect on alterations in PKA pathway. In order to investigate the possible involvement of NCS-1 in cAMP / PKA / DARPP-32 pathway we have used PC12 cells of wild type (wt) and a cell line stably overexpressing NCS-1 (Clone). Western blot analysis demonstrated that Clone cells has downregulation of DARPP-32 expression and levels of pDARPP-32(Thr34) and pCREB(Ser133). Also, ELISA analysis showed decrease in cAMP levels in Clone cells. However, there are no alterations in pDARPP-32(Thr75) levels and expression of D2 receptors, CREB and Calcyon. Also, we observed that there were no alterations in pDARPP-32(Thr34) levels after treatments with dopaminergic agonists and antagonists. These results indicate that PC12 cells are a suitable model to dissect the important signaling pathways modulated by DARPP-32 and NCS-1 which may have the potential to turn into therapeutic targets for the treatment of serious psychiatric diseases.

5. M. Franceschi
6. G. Comi, MD
7. L. Leocani, MD, PhD

Aim: Search for correlation between cognitive tests performance and EEG data in adults with Down's syndrome (DS).

Subjects: Twenty-five adults with DS underwent 32-channel EEG (eyes closed, auditory odd-ball paradigm) and a neuropsychological battery. Quantitative EEG (absolute power) and ERPs were tested for correlation (Spearman rank test) with psychometric scores and linear regression was applied for significantly correlated variable pairs. Comparison of EEG absolute power between DS and 25 control subjects was performed using LORETA.

Results: The Mini mental state examination (MMSE) test correlated negatively with the latency of P200 [r = -0.417 (p:0.038)]. Wechsler Adult Intelligence Scale (WAIS)-total: a positive correlation with the amplitude of N100 [r = 0.592 (p:0.003)] and a negative correlation with the maximum absolute power in the occipital regions [r = -0.452 (p:0.023)] was found. Rivermead Behaviour Memory Performance correlated positively with P300 amplitude [r = 0.450 (p:0.024)] and negatively with the maximum absolute power [r = -0.442 (p:0.027)]. Maximum absolute power correlated negatively with P300 amplitude [r = -0.402 (p:0.047)]. N100 amplitude was found to be predictive for P300 amplitude [r = 0.445 (p:0.021)] and WAIS performance [r = 0.527 (p:0.008)]. LORETA: DS showed excess theta in the right: hippocampus, frontal (BA 44), temporal (BA21,22) and occipital lobes. Beta1 was reduced in the left temporal lobe (BA 22).

Conclusions: Correlations between both ERP and EEG-background activity and cognitive tests' performance in adults with DS exist. The findings may be interpreted in one direction with the hypothesis about P300 as result of an inhibition process on ongoing activity. It could be speculated that the higher background activity (especially in the frontal, temporal and occipital regions) may result in more difficult inhibition and lower amplitude of P300, linked with a weak cognitive test's performance.

PRODROMAL SYMPTOMS IN MANIA

INSTITUTIONS
1. PGIMER, Psychiatry, Chandigarh, India

AUTHORS
1. Manoj Sahoo, Dr., MD
2. Subho Chakrabarti, Dr., MD, MRCPsych, MAMS, subhochd@yahoo.com
3. Paramanand Kulhara, Prof., MD, FRCPsych, FAMS

Aims/Objectives: Identifying a relapse of any disorder in its prodromal period allows for early intervention and prevents or reduces adverse consequences that can result from a full-blown episode. This study aimed to examine various aspects of prodromal symptoms of mania and to compare this with prodromes seen among patients of recurrent (unipolar) depression.

Method: The sample consisted of 30 patients with a recent manic relapse and a control group of 30 patients with recurrent (unipolar) depression who had experienced a recent relapse. Prodromal symptoms were assessed during periods of remission, using a scale specifically designed for this study and an open interview. Several characteristics of prodromes e.g. prevalence, pattern, duration were all explored and compared between mania and depression.

Results: Relatives of patients with mania were able to detect a prodromal phase significantly more often than the patients themselves. The proportion of patients with depression and their relatives reporting prodromal symptoms was, however, identical. Patients with depression had significantly longer prodromes than those with mania. Most common prodromal symptoms of mania were hostility, overactivity and ideas of grandeur and those of depression were sadness, reduced speech and lassitude.

Conclusions: Prodromal symptoms are often present in a large proportion of those with manic or depressive relapses. The prodromal phase takes several weeks to evolve into a full-blown disorder. Relatives are better able to detect early warning signs, particularly in patients with manic relapses.

2. Badar Sabir Ali¹, Dr, MD, basabir@hotmail.com
3. Syed Iqbal Azam², Mr, iqbal.azam@aku.edu

Aims/Objectives: Postpartum women are known to suffer from anxiety/depression, and are reluctant to accept pharmacotherapy for fear of exposing their neonates to drugs. This study assesses the benefit of counseling from minimally trained community health workers in reducing postpartum anxiety/depression, the rate of recurrence and the interval preceding recurrence in two underprivileged communities.

Methods: In this quasi-experimental study, literate community women were trained in screening for anxiety/depression, and in minimal counseling skills. Through a household survey they identified 113 women with postpartum anxiety/depressions, 66 of whom agreed to be counseled and were provided 8 weekly counseling sessions, they were re-screened after 4 and 8 weeks of counseling. Of those who had declined counseling 16 consented to re-screening after 4 and 8 weeks.

Results: Chi-square test was used to see the association between socio-demographic variables and counseling. Repeated Measures ANOVA was used to see the difference in the AKUADS scores between the counseled and not counseled. Kaplan Meier test was used to calculate the mean recurrence time. Significant decline in level of anxiety/depression was found in both the groups at 4 and 8 weeks (p-value=0.001). The counseled group fared modestly better than the non-counseled in reduction in anxiety/depression, rate of recurrence and in duration before relapse.

Conclusions: Counseling by minimally trained community women reduces post-partum anxiety/depression, its rate of recurrence and increases the symptom free intervals between episodes. Incorporation of counseling skills in training of community health workers could improve the care of women with postpartum anxiety and depression.

AUTHORS
1. Niloufer Sultan Ali¹, Dr, MD, niloufer.ali@aku.edu

Aims/Objectives: Globally Postpartum depression has been widely investigated because of its grave consequences; but there is paucity of data in the local context. This is a nested cross-sectional study that investigates the prevalence of depression/anxiety and their associated factors in post partum women.

Methods: A cross-sectional survey was conducted in two peri-urban, multiethnic, underprivileged communities of Karachi, a mega city of Pakistan. This was a house to house questionnaire based survey done by trained community women; 420 consenting post-partum women were interviewed and data was collected for socio-demographic, home environment, family relationship variables and levels of anxiety and depression. Mothers with depression/anxiety were identified in a two step process: initially an indigenous, validated screening instrument Aga Khan University Anxiety and Depression Scale was used and diagnostic confirmation was obtained through a psychologist’s interview based on DSM IV criteria for anxiety and depression. Only 267 women could be followed for a whole year. Data was analyzed using SPSS.

Results: A prevalence of 28.8 percent was found. Domestic abuse, difficulty in breast feeding and non-acceptance of current pregnancy were found to be significantly associated with postpartum anxiety/depression in the multivariate analysis.

Conclusion: Domestic abuse and not having the right to plan pregnancy are related to the patriarchal culture and lack of empowerment of women. The association of difficulty in breast feeding needs to be explored further to determine the role of postpartum anxiety/depression in difficulty in breast feeding or vice versa as a temporal relationship cannot be determined in a cross-sectional survey.

5. Gerd-Helge Schneider, MD
6. Andrea Kühn
7. Andreas Kupsch
8. Ion Anghelescu

Aims: Functional imaging studies in treatment resistant depression showed metabolic overactive structures of subgenual cingulate gyrus (Cg25). Deep brain stimulation of this region has been reported to have antidepressant effects. Based on these findings, we report about further clinical and neurophysiological experience with Cg25-DBS in a European sample of depressed patients.

Methods: Patients with severe therapy resistance were treated with bilateral Cg25-DBS. Double-blind testing of effects of electrode pairs (0+4, 1+5, 2+6, 3+7, sham stimulation) were performed at three levels: within the OR, for each of the five conditions for 30 minutes, and afterwards for 24 hours again for each of the conditions. Afterwards stimulation for 6 weeks was performed at the electrode pair showing the largest acute effects. Local field potentials were recorded directly from the Cg25 after presentation of emotional pictures.

Results: Acute antidepressant effects were neither reported in the OR nor after pairwise stimulation of 30 minutes duration. However, stimulation of 24 h duration revealed modest, but substantial antidepressant effects after stimulation of the electrodes 0+4 and 3+7 as compared to baseline and placebo. Presentation of negative visual stimuli led to an activation of the Cg25 as measured with local field potentials.

Conclusions: The results show that a Cg25 stimulation of only 24 hours may be capable for evoking acute antidepressant effects. Effective electrodes were the outer pairs putatively indicating that cortex stimulation may be more effective than white matter stimulation. Moreover, recording of local field potentials may be a promising approach for investigating altered emotional processing.

IMMOTENCE TO STOP A LEARNED CONDITIONAL INERTIA: ORIGIN OF THE DEPRESSION.

INSTITUTIONS
1. CENTRO DE INVESTIGACIÓN, DIFUSIÓN Y PROMOCIÓN DE LA LIBERTAD INTERIOR, RESEARCH, TRUJILLO, Peru

AUTHORS
1. Armencio Delo, armencio_delo@yahoo.com

Objective: Demonstrate that depression and uselessness feeling, of the Being, are a learned phenomenon at home, always tolerated never understood, unresolved eternally.

Method: Exploration and record of all those consciousness states produced in real I search, for 30 years.

Results: An aggressive progenitor, his impositions and Conditioned stimuli linked to this, threatening the child to produce a CHANGE IN FORM AND BEHAVIOR of the first one, of the second one and of the things (according to a social pattern), in order to obtain a reward and avoid a punishment: Implementational Mechanism of the Conditioning (MIC) exercised, reinforced and institutionalized the preceding, like survival forms, produces an apprenticeship carrying out in frustration quiet, to not be able to be, when he misleads his evolutionary step.

Conclusion: In search of real freedom, exercising MIC repeatedly through irrational acts, with analogous purposes, forcing all logic and will; for adjustment reasons and execute what was learned, the Man, without understand it nor overcome it has just consciousness of emptiness and uselessness of his Being, experiencing sadness and impotence for not be able To Be or mechanize his Life, involutional phenomenon that he can not revert but he carries, silently, as he did it time ago.

DEPRESSION IN THE GENERAL HOSPITAL: DIAGNOSTIC FAILURE IN CLINICAL WARDS

INSTITUTIONS
1. Federal University of São Paulo, Department of Psychiatry, São Paulo, Brazil

AUTHORS
1. Vinicius Y Moraes¹, Mr.
2. Thiago M Fidalgo¹, Mr., marquesfidalgo@yahoo.com.br
3. Gabriel F Rusca¹, Mr.
4. Miguel R Jorge¹, Dr., PhD, migueljorge@psiquiatria.epm.br

Introduction: About half of the patients hospitalized present sub-diagnosed and sub-treated depression. The absence of diagnosis leads to an increase of morbidity and mortality, as well as overburden the health system.

Objective: To evaluate the ability of non-psychiatrists to identify depression in a general hospital.

Methods: The study was conducted in clinical wards in a general university hospital. The Hospital Anxiety and Depression scale (HADS) was used in this research. A research assistant applied the scale while another, blind to the results of the scale, searched for any mention to psychiatric aspects of depression in the medical records.

Results: Eighty-eight patients (54.5% male and 45.5% female) were evaluated in seven clinical wards. Nineteen patients presented HADS scores compatible with depression. Nevertheless, few diagnoses were found in medical records. Using HADS as gold-standard for diagnosis, the medical diagnosis showed 15.8% of sensibility and 94.2% of specificity. There was a preponderance of psychic symptoms in the initial stage of hospitalization (p=0.05). The consultation-liaison psychiatry was solicited in four cases (4.5%).

Conclusions: These findings might indicate a lack of ability of non-psychiatrist physicians in the recognition of depression or a disregard with psychic symptoms, since some of the symptoms were transcribed in the medical records without any diagnosis action or specific treatment. The low sensibility of the depression diagnosis performed by clinical physicians indicates a necessity for improving the psychiatry-related training.

THE EFFECT OF DEPRESSIVE DISORDER ON ADHERENCE TO HIGHLY ACTIVE ANTIRETROVIRAL THERAPY IN PATIENTS WITH HIV/AIDS

INSTITUTIONS
1. Ahmadu Bello University Teaching Hospital, Psychiatry, Zaria, Nigeria

AUTHORS
1. Victor O. Olisah¹, Dr, MB,BS, FWACP, olisahvictor@yahoo.com

Aim/Objective: To determine the effect of depressive disorder on adherence to Highly Active Antiretroviral Therapy (HAART) in patients with HIV/AIDS

Method: The study was conducted at MOPD of A.B.U.T.H, Zaria. We compared adherence to highly active antiretroviral therapy (HAART) in HIV patients with depressive disorder with adherence in a similar group of patients without depression. A socio-demographic and drug adherence questionnaire was administered, Centre for Epidemiological studies Depression Scale (CES-D) was used to screen for depressive symptoms and Schedule for Clinical Assessment in Neuropsychiatry (SCAN) was used to confirm the diagnosis of depression. Data was analyzed using SPSS 12 and level of significance was set at 5%.

Results: A total of 310 patients with HIV/AIDS receiving HAART participated in the study, 31.6% were males, 68.4% female, mean age was 53.5± 8.97 years, 37.4% had secondary education while 27.1% had tertiary education. Sixty percent of subjects were Christians and 40% were Muslim, 38.7% were unemployed while 27.4% were highly skilled professionals, 21.3% had significant depressive symptoms while 14.2% met ICD10 diagnostic criteria for depression. A total of 73% of subjects had good adherence to HAART, 63.6% of subjects with depressive disorder had poor adherence to HAART compared to 21.1% of subjects without depression.

Conclusion: Depressive disorder in patients with HIV/AIDS is associated with poor adherence to antiretroviral medication. Early identification and treatment of depression in such patients is likely to improve medication adherence and treatment outcomes.

5. Sergio Paradiso, Dr., Md, PhD, sergio-paradiso@uiowa.edu

**Aims:** Apathy and anhedonia are predominant symptoms in late-life depression (LLD; onset over 50 years). Presence of cerebrovascular changes in neural substrates of motivation in LLD suggests that motivational deficits may persist after symptoms remission.

**Methods:** We compared 15 symptomatic subjects [8 F, mean age = 62.33, SD=10.75, mean Hamilton Depression Rating Scale (HDRS) = 19.93, SD=4.03]; 15 remission subjects [7 F, mean age= 66.20 SD = 7.27, mean HDRS score= 7.13, SD=6.61] and 34 healthy subjects [21F, mean age = 69.51 SD=7.75, mean HDRS score=1.53, SD=1.54]. Subjects were asked to control viewing time of eighteen randomly presented pleasant stimuli by keyboard pressing. Motivation was measured by change in viewing time from baseline (9 seconds) and hedonic appreciation by rating of pleasantness (1=very unpleasant, 5=neutral; 9=very pleasant).

**Results:** A group effect on viewing time was found ([ F(2,1182)=21.8, p<0.001]. Pairwise comparisons showed differences between currently depressed (M=0.94 seconds, SD=2.82) and comparison subjects (M=2.28, SD=2.64) (p<0.001); between subjects in remission (M=1.64, SD=3.15) and comparisons (p=0.004), and between currently depressed and remission subjects (p=0.009). There was a group effect on pleasantness [F(2,1146)=27.5, p<0.001]. Pairwise comparisons showed differences between currently depressed (M=0.74, SD=1.89) and comparisons (M=1.54, SD=1.49) (p<0.001); between currently depressed and remission subjects (M=1.65, SD=1.65). There was no difference between remission and comparisons (p>0.05).

**Conclusions:** People with symptomatic LLD showed decreased approach motivation and hedonic appreciation for pleasant stimuli. People with LLD in remission showed preserved hedonic appreciation but decreased motivation. Poor motivation in LLD does not appear to improve with remission of symptoms.

3. Johannes Pantel, Dr., MD, johannes.pantel@kgu.de
4. Johannes Schröder, Dr., MD, johannes.schroeder@med.uni-heidelberg.de

There are only a few epidemiological studies assessing prospectively the prevalence of MDD in a group of younger adults. We established the prevalence and clinical course of affective disorders within the Interdisciplinary Longitudinal Study on Adult Development and Aging (ILSE).

**Methods:** 500 subjects born between 1950 and 1952 were recruited using the community registers of Heidelberg and Leipzig. Since it is compulsory for each resident in Germany to be registered, this recruitment procedure yielded an representative community sample. In the three examination waves psychiatric disorders were assessed by using the German version of the Structured Clinical Interview for the DSM-III-R. The first examination wave (t1) was conducted in 1994-95, t2 in 1998-99, and we are currently completing the third wave (t3) which was initiated in July 2006.

**Results and discussion:** Until now, 339 patients (167 females, 172 males) of the cohort have been examined in T3. Mean age was 44.1±0.9 years at baseline (t1), 48±1.1 years at t2 and 55.0±0.9 years at t3. Life time prevalence rates of MDD for this group of patients rose from 18.6% at t1 to 22.7% at t2. Preliminary analyses of the current examination wave led to lifetime prevalence rates of 28.0%. The point prevalence of MDD was 2.4%, 2.9% and 5.0% for t1, t2 and t3 respectively. These preliminary results show an important increase in the point prevalence rate of MDD in the third wave and emphasize the high prevalence of affective disorders at this age.
BRAIN INTERLEUKIN-1 MEDIATES CHRONIC STRESS-INDUCED ANHEDONIA AND SUPPRESSION OF NEUROGENESIS VIA ADRENOCORTICAL ACTIVATION

INSTITUTIONS
1. The Hebrew University of Jerusalem, Psychology, Jerusalem, Israel

AUTHORS
1. Raz Yirmiya, Dr., PhD, razyirmiya@huji.ac.il

Several lines of evidence implicate the pro-inflammatory cytokine interleukin-1 (IL-1) in the etiology and pathophysiology of major depression. To explore the role of IL-1 in chronic stress-induced depression and in some of its underlying biological mechanisms we used the chronic mild stress (CMS) model of depression. Mice subjected to CMS for 5 weeks exhibited depressive-like symptoms, including decreased sucrose preference, reduced social exploration and adrenocortical activation, concomitantly with increased IL-1-beta levels in the hippocampus. In contrast, mice with deletion of the IL-1 receptor type I (IL-1rKO) or mice with transgenic, brain-restricted over-expression of IL-1 receptor antagonist did not display any CMS-induced behavioral or neuroendocrine changes. The blunting of the adrenocortical activation in IL-1rKO mice may play a causal role in their resistance to depression, because removal of endogenous glucocorticoids by adrenalectomy also abolished the depressive-like effects of CMS. Reduced hippocampal neurogenesis, another putative mechanism of depression, may also underlie IL-1’s involvement in CMS-induced depression, because whereas in WT mice CMS significantly reduced neurogenesis, measured by incorporation of BrdU and by doublecortin immunohistochemistry in the dentate gyrus, no such decrease was observed IL-1rKO mice. Moreover, the effects of CMS on both behavioral depression and neurogenesis could be mimicked by exogenous administration of IL-1-beta via osmotic minipumps for 4 weeks. These findings indicate that elevation in brain IL-1 levels, which characterizes many medical conditions, is both necessary and sufficient for producing the high incidence of depression found in these conditions. Thus, procedures aimed at reducing brain IL-1 levels may have potent anti-depressive actions.

1. Carlos M Grilo¹, Dr., PhD, carlos.grilo@yale.edu
2. Deborah L Reas², Dr., PhD

Aims/Objectives: To systematically evaluate controlled treatment research findings to determine the utility for BED of pharmacotherapy-only and pharmacotherapy combined with psychosocial treatments.

Methods: A meta-analysis was performed on placebo-controlled trials published 1985 thru 2008 that reported data for major outcomes.

Results: 28 studies were considered of which 14 studies with a total of 1279 patients were included in the meta-analysis of pharmacotherapy-only treatment and 8 studies with a total of 683 patients were included in the review of pharmacotherapy combined with psychosocial treatments. Evidence exists to suggest that pharmacological treatments have a clinically significant advantage over placebo for achieving short-term remission from binge eating (48.7% versus 28.5%) and for weight loss, although the weight losses are modest. There are no data to allow evaluation of longer-term effects or durability of pharmacotherapy-only for BED. Combining medications with psychosocial interventions failed to significantly enhance binge eating outcomes although promising findings have been reported for specific medications (orlistat and topiramate) to enhance weight losses achieved with cognitive behavioral and behavioral weight loss treatments.

Conclusion: Meta-analytic findings indicate BED patients can be conservatively advised that certain pharmacotherapies may enhance likelihood of stopping binge eating over the short term but that the longer-term effects of pharmacotherapy-only are unknown. Patients should be advised that although some weight loss may occur it is unlikely to be substantial with available pharmacological agents. Combining medications with cognitive behavioral or behavioral weight loss treatments is unlikely to enhance binge eating outcomes but specific medications may modestly enhance weight loss.

In 2002, The Japanese Society of Psychiatry and Neurology changed the official name of „schizophrenia” (seishinbunretsu-byo, lit. split mind disease) to a term meaning „loss of coordination disorder (togo-shicho-syo)”. The effect of merely changing a possibly stigmatic term to something new may be moot, yet there has been discussion on whether a change in the English terminology would be clinically and scientifically desirable. To attempt to gain insight into the thinking concerning this point among international psychiatric authorities, we carried out a questionnaire, sent to members of the Section on Classification, Diagnostic Assessment and Nomenclature of the World Psychiatric Association. Only approximately 25% responded, perhaps because of the sensitive/political/clinical implications of the main question - whether the term „schizophrenia” is stigmatic and should be changed. Of the 50% who did respond, a slightly greater number (10, 50%) wished the term to be changed than those who did not (35%) and 2 (10%) gave ambiguous answers and 1(5%) gave none. However, regardless of whether the respondents were for, against, or equivocal, there was a strong common refrain - there must be greater education of the public concerning the varieties of conditions that this term (or its successor) is used to cover. The comments of all the responders (psychiatry experience 5-50 years) indicated that this is an extremely important topic in terms of improving patient care in future. As a next step, we are advancing our research to a more world-wide stage. We will report the details of the results concerning renaming schizophrenia.

Objective: To evaluate the new offerings of research drugs in schizophrenia and the difficulties encountered.

Design: Review of available knowledge of newer drugs in studies for the management of schizophrenia.

Materials and Method: Review of available knowledge of ongoing research activities in the area of pharmacotherapy of schizophrenia.

Results: My own comments on ongoing activities and trends of drugs for the management of schizophrenia.

Conclusion: The present armamentarium of antipsychotic drugs has brought new hope and marked revolutionary improvement in the management of schizophrenia. However, the development of new antipsychotics has increased significantly to meet the unmet need of the present armamentarium, like reducing the treatment resistance, enhancing the optimal therapeutic efficacy with a decreased side effect profile, enhancing the control of relapse, quality of life, as well as taking advantage of the huge commercial market. This paper describes 11 of such drugs, their receptor affinities, therapeutic efficacy and the adverse reaction profiles.

Key Words: schizophrenia, antipsychotics in development, dopamine, serotonin, efficacy

Aims/Objective: Psychiatry in intellectual disabilities is challenging since it offers the chance to study psychiatric symptoms and neuropsychological dysfunctions in relation to a known etiology. The same holds for the investigation of psychiatric manifestations of neurologic diseases in which a bottom-up approach is in general followed that starts with the emergence of pathology in the brain and attempts to understand clinical syndromes out of this pathology.

Methods: In order to prepare a psychopharmacological guideline for people with intellectual disability, it became obvious that the field is severely compromised by current categorical diagnostic habits.

Results: Scrutinizing the literature about psychopharmacological treatment revealed that almost all studies deal with psychotropics applied for challenging behaviours in people with mental retardation and that current practice is dominated by totally inadequate concepts. Intellectual disability is not a disease but a metasyndrome including a very heterogeneous group of clinical maladies ranging from genetic to nutritional, infectious, metabolic or neurotoxic conditions. The IQ criterion itself is hardly informative and does not relate to specific cognitive impairments in different diseases with intellectual disabilities. The same holds for the term challenging behaviour that is an amalgam of behavioural disturbances and psychiatric symptoms. Psychopharmacological treatments based on such premises are therefore nonsensical.

Conclusions: An algorithm for psychopharmacological treatment should therefore be based on an understanding of etiology (e.g. genetic and metabolic disorders, comorbidities and environmental factors), pathophysiology (e.g. vascular anomalies and endocrine dysfunctions) and pharmacokinetic parameters related to the P450 isoenzyme system.

This study explores the effects of marijuana on a population of young scholars, who consume only this illegal drug and no other, and who have never gone to a specialist for addiction problems. The results show the effects of habitual consumption of marijuana on cognitive functions involved in the learning process. Once the subjects have been identified, individual evaluations are performed on students who consume and who do not consume in the public, subsidized public, and private education in the Metropolitan Area of Santiago, Chile. Harmful effects are found to be caused on immediate memory, attention-concentration and execution strategies in consumers, where the differences are statistically significant compared to the control group. Higher consumption is found in schools in poorer districts and a lack or shortage of perception of harm associated with the consumption of the drug especially among habitual consumers is also seen. Girls tend to consume the same amount as boys.

Keywords: Cannabis, adolescents, consumption, neurological damage, cognitive functions

First Psychotic Episode Clinic (FPEC) that provides specific service programs to this particular target group of patients opened in November 2000 as a day clinic at the Moscow Research Institute of Psychiatry (MRIP). To date, FPEC programs consistent with the MRIP model have been established in 25 regions across Russia. The principles of the follow-up management of the illness after treatment in FPEC are the same as of initial treatment with the focus on continuity of care: decrease of duration of untreated psychosis; services within the least restrictive approach, both in the in-patient settings (with initial or early transition to day treatment schedule) and at the following outpatient treatment stages; primary use of atypical neuroleptics; combining biological treatments with psychosocial interventions; long-term follow up with individualized case manage-ment: family involvement in treatment and rehabilitation process. 5-year follow-up data are available for 114 patients who received such care in MRIP clinic. In more than 30% of cases complete remission was maintained during 5 years. The number of relapses increased on the 2nd and 3rd years, but later decreased more than by one half. The relapses were mostly treated in outpatient settings and didn't require hospital admissions. More than 73% of the patients maintained their social achievements with no losses. By the end of the 5th year only 1/5 of the cases were formally recognized as unemployable due to psychiatric disability. Significantly better clinical and psychosocial outcomes have been shown in comparison with control group of patients, treated in routine psychiatric services.

THE RELIGION AS COMPLEMENTAL RESOURCE IN THE SOCIAL THERAPY

INSTITUTIONS
1. Brazilian Association of Cultural Psychiatry, Florianópolis, Brazil
2. Brazilian Federation of Psicodrama, São Paulo, Brazil

AUTHORS
1. Marcos de Noronha1,2, Dr., MD, marcos@abe.org.br

The video presents the surgeries spiritualists practiced by a bricklayer in the center of Brazil, that, among other objects, He used electric mountain to open the patients’ bodies; images of a Catholic Friar making cure the distance and for imposition of hands and finally, an African ritual in Senegal. The discussion is made by the participants due to the perplexity of the presented scenes and of the power of cure of the act, its symbolic communication and the understanding of this practice with the medicine.

The religions also carry out differently the reception paper and treatment of the “diseases of the soul” in many countries. In this classification great part of the psychiatric diseases is included, whose cause is attributed the disturbances of the soul, attacks of spirits of ancestral, among other deliberate evil. In Brazil, so much Christian religions, as animists, they enlarge your legion of having converted with cure practices being constituted reference for the local population.

INTERACTIONS BETWEEN DRUGS OF ABUSE AND PSYCHOTROPIC MEDICATIONS

INSTITUTIONS
1. Melbourne Health, NorthWest Mental Health, Melbourne, Australia
2. Western Health, Drug & Alcohol Service, Melbourne, Australia

AUTHORS
1. Enrico Cementon1,2, Dr, MBBS FRANZCP, Enrico.Cementon@mh.org.au

Aims/Objectives

One challenge in treating people with both mental illness and substance use problems, or so-called, ‘dual diagnosis’, is prescribing psychotropic medication when there is a history of substance misuse. All psychotropic medications have psychoactive effects and are therefore drugs that are at risk of misuse. Furthermore, in the setting of simultaneous administration, there exists the risk of interactions between the prescribed psychotropic medications and the drugs that are not prescribed or are illegally obtained. This paper will outline some of the issues that arise in the clinical context of combined use of psychiatric drugs and substances of misuse.

Methods
There will be explanations of the pharmacological, pharmacokinetic and pharmacodynamic principles that underlie medication-drug interactions and examples of these interactions drawing on the literature. There will also be exploration of the clinical impact of these interactions, including the resulting consequences and complications.

Results
Interactions between drugs of abuse and psychotropic medications may be described as additive, synergistic and antagonistic. Drug overdose deaths and the serotonin syndrome are examples of the severe consequences of some interactions. However there is a wide range of interactions’ outcomes.

Conclusions
Interactions between drugs of abuse and psychotropic medications are often unpredictable. There is a dearth of research evidence and literature in this important area. The psychiatrist must apply basic pharmacological principles in order to make informed decisions regarding choices of treatment and doses. The treatment of these patients usually requires closer monitoring and frequent review. Harm reduction strategies must address issues of drug-medication interaction.

2. Dimitris Agouridas²,³, Mr.
3. Yosmaoglu Ahmet¹, Dr., MD

Perhaps the problem of articulation continues being posed with a somewhat exaggerated exclusiveness, as a problem of transference or exchange, in the best of occasions, between fields of knowledge, and, indeed, often without problematizing its subject. Nevertheless, the emergence of specific nosographic entities, however contested they may be, in the clinical field could allow for articulations that go beyond mechanic elaborations, as well as for the challenging of disciplinary boundaries by their traversal, while giving rise to a multitude of possibilities related to the interpretation of an array of phenomena, remaining, at the same time, firmly rooted in the investigation of subjectivity, not by any means excluding the subjectivity of the investigator himself. In this context, what is being investigated, as an illustration of our problematic, is the entanglement of modern subjectivity with tourism, through the theoretical development of an analysis of the Stendhal syndrome. What is underlined, in this respect, is the necessity for the unfolding of a discourse initiated by the conceptualisation of the syndrome by Magherini, as consequent to the confrontation with masterpieces, and reviewed by Haddad and Haddad, as manifesting the traumatic core of travel, to be structurally found at the very centre of subjectivity. In this fashion, the ‘Great Traveller’ of Catalano, becomes the modern subject itself.

HUMANITIES ARE BEST HEALING FACTOR IN PSYCHIATRY TREATMENT

INSTITUTIONS
1. Calcutta Pavlov Hospital, Psychiatry, Kolkata, India

AUTHORS
1. Asis Krishna Acharya¹, Dr., D.I.H, D.P.M, dr_asisacharya@yahoo.com

Objective: Psychiatry as well medicine is science & evidenced based subjects mainly. Arts and humanities are some additional inputs needed in these disciple for evaluation, treatment & outcome in a long run where human quality are added to the regimen to substantial degree. It may be true for any treatment or healing process, but in psychiatry this humanities and human qualities are almost essential for a satisfactory recovery as well in a emotional crisis or in an ali-ed problem. Methods: In Calcutta Pavlov Hospital Indoor 3o males & 30 females were chosen in the age group of 20-40 years without there diagnostic specification. Majority of them (nearly 60%) were schizophrenic. rest 30 were of affective sufferers and remaining 10% others category of patients. By a NGO-Anjali, 50% of them were given some rehabilatory training, painting, and singing training as per their capacity for 6 months in a fort night interval. They were also arranged for regular family visits in addition, that is almost absent in other pt. gr. Results: A dramatic 50% improvement clinically and also administering PANS score and CGI score reveals a nearly 50-60% of overall improvement in this group in comparism to the other remaining gr. not interfered. Conclusions: Both humanities and humanarain approach in mentally ill patient can give them a better outcome than either drugs only.

SELF-AWARENESS AND INNER TIME CONSCIOUSNESS IN PATIENTS SUFFERING FROM BIPOLAR DISORDER

INSTITUTIONS
1. Medical School of Hannover, Psychiatry, Hannover, Germany

AUTHORS
1. Catharina Bonnemann

Self-consciousness of patients suffering from affective disorders has long been of special interest for phenomenological considerations. Formerly, temporality has been supposed to be a fundamental dimension of consciousness which pre-reflectively bestows an inner coherence on all of our experience. Taking Husserl's concept of "internal time consciousness" into consideration, it is found that the capability of integrating the sequence of single moments is a basis for the continuity of the self over time.

Aim of this contribution is a phenomenological approach to inner time consciousness as well as self-awareness in persons suffering from bipolar disorder. Interviews with patients demonstrate different modes of time-experience during the respective episodes. In respect of Husserl's model of retentional-impressional-protentional structure of consciousness, "nowness" is taken into consideration. It is found that the two poles of mood in bipolar disorder are characterized by quite opposite states of inner time-consciousness as well as of self-awareness. "During manic episodes, the concerned persons often construct irreal and rapidly changing self-concepts whereas they blend out their so-called "narrative identity". Here, "nowness" underlies rapid replacements, which leads to - in Ludwig Binswanger's words - a "loosening of the stream of time". The depressed person on the other hand is directed in a backwards direction. Suffering from the present state, he turns away from nowness, being dominated by his own insight.

EVIDENCE OF THE SALUTOGENIC FRAMEWORK FOR MENTAL HEALTH PROMOTION

INSTITUTIONS
1. Folkhalsan Research Centre, Health Promotion Research Programme, Helsinki, Finland

AUTHORS
1. Monica Eriksson, Mrs., PhD, monica.eriksson@folkhalsan.fi
2. Bengt Lindstrom, Mr, MD, PhD, bengt.lindstrom@folkhalsan.fi

Objective: Social trends point to a major upset of the traditional social structures such as the rupture of local and intimate networks, changed function and structure of family networks and changes in the patterns of working life. All this makes it difficult to find and run a coherent life. The aim of the presented research is to provide a comprehensive understanding of research focusing on resources of health, especially the salutogenic concept Sense of Coherence (SOC) and its relation with mental health.

Methods: A worldwide systematic and analytical research synthesis, the most extensive available to date, 1992-2003 based on about 500 scientific papers completed with papers after 2003 until to date.

Results: The synthesis shows SOC is strongly related to perceived good health, especially mental health. SOC seems to have a main, moderating or mediating role in the explanation of health. Further, the SOC reduces stress and predicts perceived good health and quality of life. The review proves that the SOC questionnaire is a valid, reliable and cross-culturally applicable instrument for measuring health. In addition, salutogenesis could be understood as a lifelong learning process aiming to the maintenance and development of peoples' health.

Conclusions: The salutogenic framework is a valuable approach and could guide public health, health promotion research and practice in a new direction.

OC-20-05
ETHICS AND NEUTRALITY IN PSYCHIATRY AND PSYCHOTHERAPY

INSTITUTIONS
1. HUG, Psychiatry, Division of adult psychiatry, Chêne-Bourg, Switzerland

AUTHORS
1. François Ferrero, Professor, francois.ferrero@hcuge.ch

Aims/objectives: This presentation emphasizes the importance of ethical principles in psychiatry and psychotherapy.
Methods: A brief historical overview of ethical principles such as beneficence, autonomy and justice will be followed by a discussion of the concept of "neutrality" in psychiatry and psychotherapy based on a range of sources in recent literature. A patient followed by Freud will also be used as an example.
Results: Training in ethics doesn't seem to be a priority in the curriculum of medical students. A re-evaluation of the application of these principles reveals a gap between theory and practice.
Conclusion: 1. These principles are culture-dependant, and they are in constant evolution, especially regarding the relative importance of each principle. 2. Ethics training seems crucial in the curriculum of medical students, as well as in the postgraduate training of psychiatrists and psychotherapists.

JUSTINUS KERNER AND THE „SEERESS OF PREVORST“

INSTITUTIONS
1. University Medical Hospital, Internal Medicine VI, Tübingen, Germany

AUTHORS
1. Steffen Oliver Häfner, Dr., MD, steffen.haefner@med.uni-tuebingen.de

The German physician and poet Justinus Kerner (1786-1862), Swabian public health officer in Weinsberg, was an allround, even an epoch-making personality in his time and a natural scientist typical for late romanticism. His greatest merit is not due to his poetical scripts, but to his scientific work. This begins with his medical dissertation "Observata de functione singularum partium auris" - a mine of experimental behaviorism. A highlight and up to now an example of pure natural science is his first description of "Botulismus" - 70 years before this was identified caused by anaerobic microbes. Treating this disease he described the use of a gastric tube, 50 years before such experiments were recorded officially. Justinus Kerner’s first contact with animal magnetism was in 1797, when he was magnetized and healed from Dr. Eberhard Gmelin, one of the first mesmerian doctors in Germany, because of his nervous stomach. With the "Seeress of Prevorst" the author ventured to advance into deep layers of the soul unknown so far. During the years 1826-1829 Justinus Kerner treated Friederike Hauffe (1801-1829), the "Seeress of Prevorst", at his Weinsberg domicile. In the year 1829 he published the description of her life and disease with the title "The Seeress of Prevorst", being revelations concerning the inner-life of man, and the interdiffusion of a world of spirits in the one we inhabit. He left volumes of psychopathological case histories and helped to prepare a way for a medicine more psychotherapeutically founded.

GLOBALISATION, FATHERLESS SOCIETIES

INSTITUTIONS
1. Béla Gálfi Psychiatric Hospital, Scientific Director, Pomáz, Hungary

AUTHORS
1. Ida Kosza¹, Dr., MD PhD Prof, kosza@mail.datanet.hu

The religion as a jang principle gave an explanation of the Creation for the humanity, and gave an ancient father figure in the Person of God-Father. The Father, the Creator, who gave the strength is the jang, and the jin is the Holy Spirit. The female principle, the Mother is the acceptor, the gentleness. These factors assured of a high moral teaching for the humanity. The communist ideology deprived the humanity of this god-figure. They gave new father-figures, the pseudo-fathers. This started to destroy the ancient family-model, what is father-mother and children. The globalisation continued this process, to make disturbances in the sexual roles. Richard Rohr is dealing with the father-son archetypes. He says, the authentic fathers give strength for their sons to break off, and to become real fathers. The other type of sons, who never had real father-figures, father example with missing identity, represents in the society the passive part. They can be manipulated by the pseudo-fathers, by the lords of globalisation. They are the plaything of them, slaves. The strong sons are not preferred by these lords, because they become the active part of the society and never slaves. The globalisation makes every effort to make disturbances of sexual roles. The men will become feminine, and the women will become masculine. The ancient family model is in danger. Our mission to tell the truth to help the society in self-protection.

OC-20-08
MENTAL CAPACITY FOR TREATMENT DECISION IN VERY MILD DEMENTIA

INSTITUTIONS
1. Chinese University of Hong Kong, Psychiatry, Hong Kong, Hong Kong Special Administrative Region of China

AUTHORS
1. Linda CW Lam¹, Dr, MD, cwlam@cuhk.edu.hk
2. Victor WC Lui², Dr, lwcl807@ha.org.hk
3. Daisy NY Luk³, Dr

Background: Increasing life expectancy is associated with risks of cognitive impairment and need to face treatment decision. It would be important to examine the mental capacity to consent for treatment, especially in subjects with no obvious cognitive impairment.

Methods: Fifty-six Chinese community-dwelling older adults (aged from 65 to 87) were recruited. Mental capacity for treatment of dementia was assessed by the Chinese version of the MacArthur Competence Assessment Tool - Treatment (MacCAT-T). Cognitive function was assessed by the Clinical Dementia Rating (CDR), Mini-mental state examination (MMSE), Alzheimer’s Disease Assessment Scale - Cognitive subscale (ADAS-Cog) and verbal fluency (CVFT).

Results: 33 subjects were not demented (CDR 0), 23 were suffering from very mild dementia (CDR 0.5). According to global MacCAT-T, 79% of CDR 0 subjects were considered capable and 50% of CDR 0.5 subjects were incapable of making consent (p=0.026). Mental Capacity was significantly associated with delayed recall (p=0.001), ADAS-Cog (p=0.001) and CVFT (p=0.003) (partial correlation controlled for age and educational attainment). Eight subjects (15.3%, 6 CDR 0 and 2 CDR 0.5) were rated as incompetent before the MacCAT-T interview, and became competent after the assessment interview with MacCAT-T.

Conclusion: 50% of the CDR 0.5 subjects were rated as mentally not competent to consent for treatment. This showed that careful evaluation is required for treatment decision making capacity, even in persons with no obvious signs of dementia. Cognitive function is an important determinant for mental capacity. However, explanation of materials may improve mental capacity in subjects with no obvious clinical dementia.
THE FROZEN TIME IN PSYCHOSIS: FREUD’S ANALYSIS OF JENSEN’S GRADIVA AND PIRANDELLO’S HENRY IV

1. Psychiatric Hospital of Attica, 10th Psychiatric Department, Athens, Greece
2. Hellenic Psychiatric Association, Art and Psychiatry, Athens, Greece

AUTHORS
1. Ilias I Vlachos1,2, Mr, MD

5. Christos Tsopelas1, Mr, MD
6. Vasiliki Pante1, Mrs, MD
7. Nicolas Tzavaras2, Professor, MD, PhD

The stillness of time in psychosis becomes evident in the analysis of Jensen’s Gradiva by Freud, where the young archaeologist Norbert falls in love with the relic of a long ago deceased Pompeian woman, called Gradiva, and gradually retreats from his everyday activity into delusion, only to return after the intervention of his fiancée, Zoe, who pretends to be the relic that comes to life (Zoe meaning life in Greek). In Pirandello’s play, the protagonist -while being dressed up during a masquerade as Henry IV, the German emperor,- suffers a craniocerebral injury caused by his rival for the love of the same woman. For 20 years, he lives in an appropriately decorated villa, holding that he is the emperor in the 26th year of his age. His nephew, the woman he had loved and his rival come and organize a revival of the masquerade in order to bring him back to real time with unforeseen consequences for all. Moreover, we present the case of a young, schizophrenic mathematician hospitalized in the Psychiatric Hospital of Attica-Athens in 2007, who insisted that he was still 16, although he had already reached his 32nd year. The topics of stillness of time in psychosis, the clinging to the past as a refuge from the present, along with the issue of whether or not a psychiatrist is ethically justified to destroy a “soothing” delusion are being discussed.

**DILEMMA IN THE TREATMENT OF ACUTE DEPRESSIVE PHASE OF BIPOLAR DISORDER**

**INSTITUTIONS**
1. Calcutt Pavlov Hospital, Psychiatry, Kolkata, India

**AUTHORS**
1. Asis Krishna Acharya¹, Dr., DPM, DIH, dr_asisacharya@yahoo.com

**INTRODUCTION:** Bipolar Disorder (BD) is hazardous and costly, causes a prolonged suffering, and is associated with enormous public health burden. It is the 9th leading cause of DALY’s (disability adjusted life years) as per WHO it is 7th leading cause for DALY’s in females. Manic phases are brief and accounts for 8-14% of total illness. Span of depressive, mixed & dysphoric spells are more pronounced and difficult to manage. Family discord, violence, crime, alcohol & substance abuse, cardiovascular disorders and suicide is more in BD. Treatment in depressive phase is very less documented. USFDA has approved for the first time one combined pharmacological therapy – Fluoxetine+Olanzapine in 2004. Another promising molecule is quetiapine 300mg/day regimen.

**METHODS:** In the psychiatry out-patients-department of Calcutta Pavlov Hospital, Kolkata, total 288 patients both male and female within age range of 33-58 years, who were diagnosed as suffering from bipolar I depression (As per DSM-4 criteria) were divided in 4 groups of 72 each maintaining heterogeneity. 1st group receive only olanzapine-fluoxetine combination for 6 months and was reviewed fortnightly clinically as well as administering MADRS-d scale for a period of 6 months in 14 day’s interval. 2nd group, In addition receive lithium(600-1200Mg/d to achieve serum level>6meq/l) 3rd group receive lithium-olanzapine-fluoxetine and additional lamotrigine in25-50mg/d. 4th group receives only quitaipine 300mg/day and lithium.

**RESULTS:** All the groups shows significant improvement from 1st follow-up. 3rd group with lithium-olanzapine-fluoxetine-lamotrigine shows highest improvement followed by olanzapine-fluoxetine gr. and then quitaipine-lithium gr. who show improvement specially in pan-anxiety and sleep dominion.

**CONCLUSIONS:** In treating very difficult and dysphoric bipolar type I depression, combination therapy with lithium-olanzapine-fluoxetine & lamotrigine may show a promising results if properly more studies are conducted in similar ways.

2. Nasrin Homaily¹, Ms., MA, usha.barahmand@gmail.com

The purpose of the present study was to compare attachment styles, dysfunctional attitudes and intolerance of uncertainty in patients with generalized anxiety disorder, obsessive compulsive disorder and depression. The study sample comprised 120 individuals (40 individuals with generalized anxiety disorder, 40 with obsessive compulsive disorder and 40 with depression), matched on age and sex. To examine the variables under study, The Close Experiences Questionnaire, Relationship Questionnaire, Relationship Questionnaire, Relationship Questionnaire, Dysfunctional Attitudes Scale, Intolerance of Uncertainty Scale, Beck Depression Inventory, and Beck Anxiety Inventory were administered. Data was analyzed using descriptive statistics (frequency distributions, means and standard deviations) and inferential statistics (chi square, Pearson’s correlation, multivariate analysis of variance and discriminant analysis). The main findings of the study were as follows: attachment styles in the clinical groups differed, with generalized anxiety and obsessive compulsive patients reporting preoccupied attachment styles and depressed patients reporting dismissive attachment style; depressive also tended to report excessive parental control, increased parental rejection and low parental care; dysfunctional attitudes were significantly greater among the depressed and generalized anxiety groups than among the obsessive compulsive group; obsessive compulsive patients endorsed higher levels of intolerance of uncertainty than the other two clinical groups. Discriminant analysis revealed that intolerance of uncertainty and the anxious dimension of attachment differentiated the depressed from the obsessive compulsive group, while dysfunctional attitudes and the avoidant dimension of attachment discriminated the depressed and obsessive compulsive groups from the generalized anxiety group.

5. Enra Suljic-Mehmedika, Dr, MD,PhD, enra@lol.ba

Background: Our clinical experience in working with survivors suffering from chronic PTSD, can not prevent us from noticing frequent changes in serum lipid levels that are being associated with an increased risk of cardiovascular disorders. This is consistent with another clinical observation of increased cardiovascular morbidity in this group of patients, and also congruent with published reports in the literature.

Methods: The subjects were 100 veterans, age 40-50, who met the inclusion criteria for the study and who signed the informed consent to participate in this study. They were divided in two groups of 50: Experimental group of 50 subjects who meet the criteria for the diagnosis of chronic PTSD according to ICD-10 and the Control group consisted of 50 subjects not meeting the criteria for chronic PTSD. The groups were homogenized according to other factors influencing serum lipid levels (BMI, smoking, medical conditions, and medications affecting lipid levels). The following standardized psychometric instruments were used for assessments: MINI, Folkman-Lazarus Coping Strategies Questionnaire, BSI, IES-90 R, Mississippi Questionnaire; MANSA; Life Stressor List and a socio-demographic questionnaire. Blood lipid levels were determined and the risk factors calculated (ATPIII).

Results: Concentration of serum lipids and the risk factors for atherosclerosis and coronary disease were significantly higher in the experimental group compared with the control group.

Conclusions: The results of this study provide further evidence for the correlation of chronic PTSD and the increased values of serum lipids and risk factors for atherosclerosis and coronary disease.

Key words: chronic PTSD, cardiovascular risks, atherosclerosis, veterans

AUTHORS
1. Sandeep Govil, Dr., DNB, drsandeep.govil@gmail.com
2. Somnath Sengupta, Dr., MD
3. Praveen Sharma, Dr., MD
4. Deepak Kumar, Dr., MD, DNB

A cross sectional study was conducted to examine the nature of insight in schizophrenia and bipolar disorder as well as compare it between the two disorders. Forty patients with schizophrenia and forty patients with bipolar disorder matched on age, age of onset of illness and duration of illness, were recruited consecutively from the outpatient clinic of a psychiatric hospital. The patients had to be clinically stable on follow-up treatment for at least three months. Insight was measured using Schedule for Assessment of Insight- Extended Version (SAI-E) and Scale of Unawareness of Mental Disorders (SUMD). Both schizophrenia and bipolar disorder had modest level of insight as measured on both the instruments. There was no qualitative difference in insight between the two disorders. However, patients with bipolar disorder had significantly better awareness of illness than patients with schizophrenia. This was evident on both the instruments that showed significant concordance on the items of insight for both the disorders.

**NEED ALERT FOR METABOLIC ABNORMALITIES BEFORE INITIATING ACUTE PHASE TREATMENT OF BIPOLAR DISORDER**

**INSTITUTIONS**
1. Asan Medical Center, Psychiatry, Seoul, Republic of Korea

**AUTHORS**
1. Byungsu Kim1, Dr., MD, PhD, j993601@empal.com
2. Sang Eok Kim1, Dr, MD, PhD
3. Hui Joon Park1, Dr, MD
4. Seong Yoon Kim1, Dr, MD, PhD
5. Yeon Ho Joo1, Dr, MD, PhD

**Aims/Objectives:** There has been a rise of concerns about metabolic abnormalities in bipolar patients. This study was performed to assess the prevalence of metabolic abnormalities in bipolar patients who were in the state of initiating acute treatment for mood episode and to identify clinical correlates associated with risk of metabolic abnormalities.

**Methods:** Authors retrospectively evaluated 184 bipolar patients, who were hospitalized to treat acute mood episode from January, 2005 to December, 2006 in a university hospital (Seoul, Korea). We collected data on metabolic parameters (BMI, fasting plasma glucose (FPG), and total cholesterol) tested before initiating medication(s) and clinical correlates were evaluated.

**Results:** Bipolar patients who met the criteria of the obesity for Asian (BMI≥25) were 56 (30.4%). Fifty-eight patients (43.5%) had the risk for diabetes (FPG ≥110 or taking oral hypoglycemic agents). The subjects who showed high cholesterol level (or taking cholesterol lowering drug) were 38 (20.7%). Among the clinical variables, male sex (P=0.007), depressive and mixed state (versus manic; P=0.011), and lower educational level (P=0.012) had statistical significance. We could not observe any significant correlates for high cholesterol level. Previous atypical antipsychotic use did not significantly affect on BMI, FPG, and cholesterol.

**Conclusion:** Metabolic abnormalities are prevalent before initiating acute treatment in bipolar patients. Physicians should be alert for the risk of obesity and diabetes, and strictly perform screening for metabolic problems before initiating acute treatment.

4. John M. Oldham3, Dr., MD  
5. Timothy S. Carey1, Dr., MD

Introduction: Major advances have been made in numbers and types of medications for psychiatric illness. As the number of medications within a class increases, so does the complexity of prescriber decision-making. Systematic reviews of a medication class can inform the prescription of appropriate and effective treatments but reports generated by these reviews are often cumbersome and not used by clinicians to inform prescribing.

Objectives: To help clinicians utilize drug effectiveness reviews to improve patient care and reduce drug expenditures.

Method: A case study approach was used to describe the process of converting the more than 700-page May 2006 Drug Effectiveness Review Project Report on the use of antiepileptic drugs (AEDs) for treating mood disorders to 10 key concepts and 4 key messages relevant to AED prescribing. We will describe our product development process and our use of proven marketing strategies to increase the likelihood that this and other drug class reviews are understood and used by clinicians. We will also report audience research findings.

Results: Our results will help conference participants gain an understanding of how drug effectiveness reviews are conducted and their results interpreted for clinical practice. They will learn how evidence-based dissemination strategies are designed to accelerate incorporation of available evidence into practice.

Conclusions: As drug effectiveness reviews of agents within a drug class are developed, it is expected that clinicians use them to improve patient care. We address the dual challenge of interpreting available evidence from drug reviews and disseminating and incorporating this evidence into practice.

2. Gabriela T. Kuzmanovska1, Dr., MD, gabi_nuvola2000@yahoo.com

Aims/Objectives: Dramatherapy has as its main focus the intentional use of healing aspects of drama and theatre as the therapeutic process. This short study is aimed to find out whether drama therapy is effective for anxiety disorders (AD).

Methods: The study includes a sample of 20 patients with AD, treated with pharmacotherapy and additional 3 months drama therapy program. The treatment outcome was compared to the control group of 20 other patients with AD, stratified with the study group by age, sex and diagnosis, treated with pharmacotherapy only. We used adapted Stanislavskian theatre techniques which incorporated the production of theatre performances followed by systematic reflection. HAM-A and HAM-D scales were performed, measuring potential changes in anxiety and depressive scores in examined patients with AD.

Results: As determined by reduction in total HAM-A and HAM-D scores, drama therapy in addition of pharmacotherapy was with more positive response for reducing symptoms of anxiety and depressive symptoms than the control group and demonstrated a significant decrease in HAM-A scores from baseline (13.9 ± 4.4 to 8.9 ± 4.3).

Conclusion: Dramatherapy is effective for short-term treatment of AD in reducing anxiety symptoms and secondary symptoms of worry and depression. It encourage clients to develop an ability to express the whole range of their emotions and to increase their insight and knowledge of themselves and others. Dramatherapy enable clients to release their own „inspirational creativity” and become „spect-actors” which helps the client take responsibility for his/her own life through the use of aesthetic distance and theatrical metaphors.
ASSOCIATION BETWEEN MOOD STABILIZERS AND ADVERSE CUTANEOUS DRUG REACTIONS IN PATIENTS WITH BIPOLAR DISORDERS - A NESTED MATCHED CASE-CONTROL STUDY

OBJECTIVES: This study investigated the association between mood stabilizers (carbamazepine and valproate) and the risks of erythema multiforme (EM), Stevens-Johnson syndrome (SJS), or toxic epidermal necrolysis (TEN) among patients with bipolar disorders.

METHODS: This is a nested matched case-control study using the data of patients with bipolar disorders from the Psychiatric Inpatient Medical Claims (PIMC) data between March 1997 and December 2004. We identified 72 patients with bipolar disorders who had an inpatient or outpatient diagnosis of EM, SJS or TEN by ICD-9-CM code of 695.1 and 288 controls with the absence of EM/SJS/TEN diagnosis and matched for sex, age, and index day. The use of carbamazepine, valproate, and other medications during the 60 days prior to the index date of diagnosis of EM/SJS/TEN were compared.

RESULTS: Results showed that carbamazepine (odds ratio, OR = 3.7; 95% confidence intervals, CI = 2.0-6.8) and valproate (OR = 2.2; 95% CI = 1.2-4.2) significantly predicted EM/SJS/TEN. Other significant predictors for EM/SJS/TEN included other anticonvulsants (phenytoin, phenobarbital and lamotrigine), cephalosporin, some non-steroid anti-inflammatory drugs (acetic acid derivatives and fenamates (mefenamic acid)), salicylates, and acetaminophen. The most predictive exposures were carbamazepine, valproate, other anticonvulsants, and acetaminophen. We also found the combination of carbamazepine and acetaminophen further increased the risk for the occurrence of EM/SJS/TEN. There was no interaction effect from age and gender.

CONCLUSION: Similar to Western studies, this study suggests that carbamazepine and valproate increased risks for EM/SJS/TEN. We should be cautious about the combined use of carbamazepine and acetaminophen.

SPECIAL NEEDS OF INDIGENOUS CHILDREN AND ADOLESCENTS IN AUSTRALIA

INSTITUTIONS
1. Barwon Health, Psychiatry, Geelong, Australia
2. University of Melbourne, Law, Melbourne, Australia

AUTHORS
1. Anna Datta, Dr., MD., anna828359@yahoo.com
2. Justin J Frewen, Mr., MA, cead_milte@yahoo.co.uk

Aims: Through available hardcopy and online literature 1/ assess and evaluate impact of socio-cultural context and environment upon treatment for alleged psychiatric problems of indigenous children and adolescents in Australia. 2/ Assess and evaluate coverage of range of pertinent issues including, mainstream knowledge and understanding of family and community culture in which Aboriginal children/adolescents live; categorisation of indigenous children/adolescents affected by cultural and social misunderstandings; communication issues due to cultural differences and/or linguistic issues; impact of sense of exclusion and/or discrimination upon indigenous children/adolescents; role of racism in tendency to believe indigenous children/adolescents have mental problems more quickly than those from non-indigenous community; apprehension of involvement in treatment process; different expectations on part of indigenous families from those of mainstream specialists with respect to treatment process and objectives.

Methods: Rigorous review of relevant and applicable hardcopy and internet literature in English language since 2000 with particular emphasis on indigenous children/adolescents in Australia.

Results: Problems associated with Aboriginal children/adolescents generally multi-dimensional and require additional assistance through family and community oriented mental health services that respect and understand cultural values and way of life of Australia’s indigenous population. Furthermore, awareness of discrimination and exclusion that has been and is suffered by Australia’s indigenous population is essential in responding to psychiatric needs of indigenous children/adolescents.

Conclusion: History of discrimination and exclusion together with lack of cultural understanding and empathy have often hampered effective treatment of indigenous children/adolescents in Australia. Need for greater involvement of indigenous communities in psychiatric treatment process.

THE SYNDROME OF DELIRIUM IN CHILDHOOD AND ADOLESCENCE

INSTITUTIONS
1. University of Cape Town, Division of Child and Adolescent Psychiatry, Cape Town, South Africa
2. Red Cross Children’s Hospital, Division of Child and Adolescent Psychiatry, Cape Town, South Africa

AUTHORS

2. Alan J Fisher, Prof.

Aim: To describe a series of children and adolescents with delirium and to consolidate the limited available literature relating to delirium in this age group

Method: A case series of 21 patients (age range 2-16 years) with a diagnosis of delirium referred to a pediatric consultation-liaison psychiatry service AND A systematic review of the literature published in any language between 1980 and 2007

Results: The literature relating to delirium in this age group consists for the most part of a small number of case series and case reports. Limited evidence suggests an increased propensity to delirium among children, and males in particular, especially when febrile and on emergence from anaesthesia. The clinical picture closely resembles that seen in adults. Cases of delirium referred to child psychiatry are often associated with complex multifactorial or uncertain aetiology, protracted course, significant morbidity and high mortality, but are less assertively treated than adult cases. The evidence-base for management is flimsy and widely varying thresholds for pharmacotherapy are described. There is most evidence for the use of haloperidol, but indications for use are unclear. Our case series documents the correlates, assessment and management of delirium in 21 patients (mean age 9.2 years) with a mean Delirium Rating Scale score of 21.5. Mortality was 19%, and the delirium markedly compromised medical care in 43%. Antipsychotic medication was used in 76%, while 24% were managed conservatively.

Conclusion: Both haloperidol and risperidone appear to be effective in cases of delirium with hallucinations, agitation, and distress. For the remainder, active environmental management may suffice.

STEP UP INDIA - A PROGRESSIVE INITIATIVE - PHASE 2

INSTITUTIONS
1. 33 Aarches Clinic, Dept. of Child & Adolescent Psychiatry, Chennai, India

AUTHORS
1. Murugan Papakumari¹, Prof., MBBS,MD,DCH,MD,DPM, mmuru100@hotmail.com
2. Murugan Manickavasagam¹, Dr., MBBS,MD,DPM,MSc,DSc, mmuru100@hotmail.com

Step Up India is an ambitious project we have embarked upon with the help of the Rotary club of Aarch City Madras - Rotary Internation District 3230. Our aim is to assess all children in Grade 6 of schools across the southern state of Tamil Nadu, India, using the Columbia Mental maturity scale, Connors behaviour rating scale and an indigenously developed learning disability rating scale. We then aim to assess the overall performance of the children and identify those falling below and also those above average level, and any behavioural or learning disability if any that may be affecting their performance. We, a group of Psychiatrists, educational psychologists and social workers, will then be educating both teachers and parents regarding the effective management of these children to help them STEP UP their level of performance.

Phase one of our project was successfully presented at Melbourne last year. We are continuing to assess schools and hope to cover 25 schools and about 4000 children in this phase. We hope to also compare the differences between the two phases.

PARALELS OF MOTHER-INFANT AND THERAPEUTIC RELATIONSHIPS IN CHILD PSYCHOANALYTIC SETTINGS

INSTITUTIONS
1. Child psychiatry and psychotherapy, Prague, Czech Republic

AUTHORS
1. Peter Pothe¹, Dr., MD, pothe@seznam.cz

The organisation of brain cells depends on endogenic and exogenic influences which take place within in an unique matrix of a mother-child relationship. The quality of the mother’s care can be observed in laboratory and clinical circumstances as it determines the child emotional growth, along with the maturation of the Limbic system, specifically its prefrontal and fronto-orbital regions. It is the quality of mother’s response to the infant’s distressed state that determines whether the infant will acquire adequate brain structures and psychological mechanisms that enable him or her to regulate negative emotions and to achieve understanding for his feelings, beliefs and motivations and the motivations of others, that is a process called mentalisation. The consequences of failures and inconsistencies in the early care will be discussed and parallels will be drawn with some behavioral syndromes, including ADHD, oppositional and conduct disorders, aggression or borderline states. The author will present clinical examples where early failures and traumas will be linked and interpreted along with pathological and dysuctional traits in the child social and emotional functioning. The author will also discuss the course of psychoanalytic psychotherapy in comparison with the influences of mother-infant interactions from the perspective of recent attachment theory findings, including the concept of mentalisation.

Bipolar disorder beginning before or soon after puberty may be a clinically different, possibly more severe, form of the disorder than older adolescent- and adult-onset bipolar disorder. The recognition of initial warning signs are grave as the disorder may progress throughout adolescence and adulthood if no intervention is made. In this study, four cases aged 5, 9, 11 and 13 years are examined. These cases were drawn from a larger sample of children and adolescents who were attended in our Child-Psychiatric Department of Tzaneio General Hospital and were assessed at high risk for developing bipolar disorder. The ‘prodromal’ symptoms, the associated features described and their clinical courses over a four-year follow-up studied to explore stability and changes over this time period.

The possible co-occurring conditions such as ADHD and ODD as well as suicidal behaviour are also studied. Developmental stages and transitions and family environmental factors that contribute to clinical and functional outcome are taken into account. Two of the four cases who at initial evaluation were assessed as being at high risk during the four-year period received a definite diagnosis of any type of bipolar disorder while the two other cases assessed as sub-threshold disorders. The predictive value of early manifestations of the disorder is discussed through these four representative cases.

The existing perspectives on diagnostic issues for bipolar disorder in pre-pubertal children and the controversial areas are also discussed.

MODEL „PROGRESS“- AS AN EARLY INTERVENTION FOR YOUTH WITH PSYCHOSIS

INSTITUTIONS
1. Mazovian Neuropsychiatry Center for Youth, Posthospitalization Department, Zagorze near Warsaw, Poland

AUTHORS
1. Anna Serafin, Mrs, MD, PhD, annaserafin@hotmail.com

Introduction: An early onset of a psychosis deeply influences later social and emotional development of adolescents. An integrative approach in post hospital rehabilitation of youth as a systemic solution is still strongly needed in many countries.

Aims: To improve the health of youth with mental disorders, increase their education levels and reinserting the youth into society.

Methods: "PROGRESS model" of supporting youth with mental disorders was created in Poland, in Zagorze near Warsaw as "a good practice" within the framework of EU EQual Program. The model was inspired by Danish experiences of intermediate care.

Results: „PROGRESS Centre“ is focused on holistic (multidimensional and coordinated) support of youth. It is a result from health, educational and social policies. The Centre it is a small, cozy institution for 10 beneficiaries. In PROGRESS under „one roof“ beneficiaries are offered individualized programs: psychiatric rehabilitation module (with pharmacological treatment, psychotherapy: individual, group and family, psycho-education and cooperation with parents), social module (with enrichment and support in everyday activities), and educational module (with general- and vocational education likewise cognitive- and creative stimulations). In PROGRESS the special focus is put on individual assistance.

Conclusion: Support in PROGRESS needs co-financing from different sources (health-, education- and social sectors) but it is worth while to invest in youth with psychosis! The choice of the right form of running PROGRESS Centre should depend on youths’ needs and local possibilities. The Project is compliant with the guidelines of the National Programme for Mental Health Protection in Poland.

3. Kyota Watanabe3, Dr., MD  
4. Masaki Kodaira4, Dr., MD  
5. Masahide Usami5, Dr., MD

Introduction: Research into outcomes of child and adolescent psychiatric inpatient treatment is scarce. This longitudinal study revealed the factors associated to better outcomes after discharge.

Method: Children admitted to child and adolescent psychiatric unit (n = 90) were assessed at baseline and at discharge during their stay from three different viewpoints, children themselves, family, and psychiatrist in charge. Data collected includes demographic data, diagnosis, Child Global Assessment Scale, Child Behavior Checklist, Youth Self Report, family factors, treatment offered during their stay, and client satisfaction. At the mean of three years after their discharge, their current situation of life such as attendance to school or work and medical history such as inpatient treatment were gathered by chart review. The factors during their stay associated to better outcome at follow up were examined.

Results: Better outcomes were associated to various factors such as symptoms at admission and family factors. More detailed results will be shown at the presentation.

Conclusion: Inpatient unit is a limited and a last resource, so only the patient who will benefit from the inpatient treatment should be admitted.

OC-22-08  
ILlicit DRUG USE AND PSYCHOPATHOLOGY AMONG JUVENILES UNDER PROBATION IN TAIWAN

INSTITUTIONS
1. Chung Shan Medical University, Department of Public Health, Taichung City, Taiwan Republic of China

AUTHORS
1. Hao-Jan Yang1, Dr., PhD  
2. Ya-Ping Liang1

Aims: To investigate the prevalence rates of illicit drugs used and psychiatric disorders among juveniles under probation.

Methods: Juveniles (n=1356) aged 12 to 20 under probation at five courts of Taiwan were consecutively recruited during January 15 to October 1, 2007. All subjects complete a face-to-face interview by well trained interviewers using the structured Mini-International Neuropsychiatric Interview.

Results: The most common used illicit drugs among juveniles under probation were nitrous oxide (1.3%), followed by ecstasy (1.2%) and amphetamine (1.0%). The prevalence rates of psychiatric disorders were also high, especially on suicidality (29.5%), psychotic disorder (29.9%), antisocial personality disorder (10.5%), and mood disorders (10.1-19.9%). The rates of psychiatric disorders went higher if subjects ever tried illicit drugs, with more than half suffering from psychotic disorder (56%) and suicidality (53%). Major depression (38%), bipolar disorder (40%), panic disorder (41%), and antisocial personality disorder (27%) also show high co-occurrences. Significant associations were found between illicit drug use and psychiatric disorders (all ORs were significantly different from unity).

Conclusion: "Club drugs" in terms of nitrous oxide, ecstasy, and amphetamine were prevalent in juveniles under probation. In addition, the high prevalence of psychopathology among juveniles under probation is also a problem to be noticed, especially among those ever tried illicit drugs. This study suggests that both drug and mental problems are important issues to be addressed among juveniles under probation. A strategy to prevent juveniles to expose to illicit drugs, especially club drugs, may be an effective way to prevent young parolees from psychiatric disorders.

LOW BONE MASS IN PREMENOPAUSAL WOMEN WITH DEPRESSION: THE POWER STUDY GROUP

INSTITUTIONS
1. NIDDK/NIMH, National Institutes of Health, Bethesda, Maryland, United States

AUTHORS
1. Giovanni Cizza1 for the Power Study Team, Dr., MD PhD MHSc, cizzag@intra.niddk.nih.gov

Aims/Objectives: An increased prevalence of low bone mineral density (BMD) has been reported in patients with major depression (MDD), mostly women. We investigated the association of MDD and BMD [1].

Methods: We report baseline BMD in 89 premenopausal women with MDD and 44 healthy control women enrolled in a prospective study of bone turnover. The BMD was measured by DXA at the spine, hip, and forearm. Mean hourly levels of plasma 24-h cytokines, 24-h urinary free cortisol and catecholamine excretion were also measured.

Results: The prevalence of low BMD, defined as a T-score of less than -1, was greater in women with MDD vs. controls at femoral neck (17% vs. 2%, P=.02) and total hip (15% vs. 2% P=.02), and tended to be greater at the lumbar spine (20% vs. 9%; P=0.14). BMD, expressed as g/cm2, was lower in women with MDD at the femoral neck (0.849 ± 0.121 vs. 0.866 ± 0.094, P=.05) and at the lumbar spine (1.024 ± 0.117 vs. 1.043 ± 0.092, P=.05) and tended to be lower at the radius (0.696 ± 0.049 vs. 0.710 ± 0.055; P=.07). Women with MDD had increased pro-inflammatory and decreased anti-inflammatory cytokines.

Conclusions: Low BMD is more prevalent in premenopausal women with MDD. The BMD deficits are comparable in magnitude to those resulting from established risk factors for osteoporosis, such as smoking and reduced calcium intake. The possible contribution of immune/inflammatory imbalance to low BMD in premenopausal women with MDD remains to be clarified.

Objectives: Deficits in response inhibition are considered as candidate endophenotype of altered prefrontal brain function in ADHD. Electrophysiological methods like Event-Related Potentials (ERPs) are adequate for the measurement of such endophenotypes. Moreover, ERPs seem to be particular suited to measure effects of functionally relevant genetic variants. This principle of imaging genetics with ERPs has been demonstrated as early as 1999 for the serotonin transporter promoter polymorphism affecting prefrontal brain function (Fallgatter et al., Int. J. Neuropsychopharmacol, 1999).

Design and Methods: We employed a multi-channel EEG during performance of a Go-NoGo task to assess the electrophysiological basis of the endophenotype response inhibition in healthy subjects and in patients with ADHD. The ERP-measure derived from this protocol was termed NoGo-Anteriorisation (NGA) and is characterized by high interindividual stability and short- and long-term test-retest reliability.

Results: In ADHD the NGA was diminished as compared matched healthy controls. Furthermore, a three-dimensional source location analysis with Low Resolution Electromagnetic Tomography (LORETA) indicated an electrical dysfunction of the medial prefrontal cortex comprising the anterior cingulate cortex (ACC) in ADHD patients in childhood as well as in adulthood. Recent studies showed a significant influence of variants of dopaminergic as well as serotonergic genes on this measure of prefrontal brain function.

Conclusions: These results exemplify the measurement of disease related disturbances in brain function with ERPs. Future studies will show whether such electrophysiological endophenotypes may contribute to the diagnosis of subgroups of ADHD and whether they may serve as endophenotypes to further clarify genetic contributions to the disease.

CREATIVITY, EVOLUTIONARY PSYCHOLOGY, PSYCHIATRY WITH PARTICULAR REFERENCE TO AUTISM AND ASPERGER’S SYNDROME

INSTITUTIONS
1. Trinity College Dublin, Child Psychiatry, Dublin, Ireland

AUTHORS
1. Michael F Fitzgerald¹, Professor, M.D., fitzi@iol.ie

Aim: To understand how creativity is associated with mental illness.

Method: Study of case histories.

Child & Adolescent Psychiatry quite rightly puts major emphasis on psychopathology and the functional impairments caused by psychopathology. Nevertheless it has been very long recognised that certain psychopathological states can have positive benefits for the individual and indeed can be adaptive. It has been shown that in ancestral environments ADHD symptoms could be adaptive and enhance survival. The presentation will discuss creative aspects of ADHD and Autism. It will focus on the extreme male brain and its relation to great creativity in the areas of science, engineering, mathematics, etc. It will examine personality traits associated with great creativity including persistence, capacity to hyperfocus, capacity for narrow focusing on detail, as well as a certain reduced interest in the wider social world. This can lead to great originality and breakthroughs. It will examine a hypothesis that multiple genes of small effect that may be significantly responsible for psychiatric conditions can also have other effects in the areas of creativity and indeed in the areas of adaptation.

5. Yu-Yu Wu⁵, Dr., MD

Objectives: To identify the determinants for switching immediate-release (IR) methylphenidate to osmotic release oral system (OROS) methylphenidate in children and adolescents with attention-deficit/hyperactivity disorder (ADHD); and to compare the effectiveness, adherence, and side effects of IR methylphenidate and OROS methylphenidate.

Method: Of the 607 children aged 5 to 16 years with a clinical diagnosis of DSM-IV ADHD enrolled in the study, 190 (31.3%) switched their medication of IR methylphenidate to OROS methylphenidate. Of them, 137 (72.1%) had poor adherence to IR methylphenidate and 170 (89.5%) were reassessed. The global ADHD severity, parent-child interaction, classroom behavior, academic performance, and side effects of the child subjects were evaluated by investigators. Parents completed the ratings scales about the ADHD-related symptoms. Parents completed the ratings scales about the ADHD-related symptoms.

Results: Determinants for switching IR methylphenidate to OROS methylphenidate included older age, high dose of methylphenidate, short duration of IR methylphenidate treatment, IQ > 70, family history of ADHD, multi-dose administration, side effect, poor adherence to IR methylphenidate, more severe inattention symptoms and global symptoms. Overall, similar side effect profile with less severity, superior adherence, and improved effectiveness in symptom reduction, parent-child interaction, classroom behaviors, and academic performance were demonstrated in intra-individual comparison of the OROS and IR methylphenidate among good and poor adherents to IR methylphenidate at Phase I. At phase II, good adherence to OROS methylphenidate endorsed better effectiveness.

Conclusion: Findings suggest that adherence predicts effectiveness of methylphenidate and OROS methylphenidate demonstrates superior effectiveness compared to IR methylphenidate regardless of adherence to IR methylphenidate.

AUTHORS
1. Lavanya Vijayaraghavan, Dr., MD
2. Sergio Paradiso, Dr., M.D., Ph.D., sergio-paradiso@uiowa.edu
3. Jatin G. Vaidya, Dr., Ph.D.

This study investigated mechanisms underlying changes in emotional perception and motivation following damage to the globus pallidus. We studied PJ, a 44 year-old man who developed bilateral, focal lesions of the globus pallidus following an episode of brain anoxia. During the three months following the anoxic episode, PJ showed the classical behavioral changes following globus pallidus lesions: greatly reduced spontaneous activity and speech, flat affect, social withdrawal, loss of interest, inability to “feel”, and lack of concern regarding his medical condition. PJ and 30 healthy male controls performed a task designed to parse hedonic evaluation from incentive motivation. The principal novelty of the task is an objective, behavioral assessment of incentive motivation (measured as viewing time controlled by keyboard key pressing) that accompanies the self-report assessment (i.e., wanting) of this construct. PJ showed hedonic appreciation of unpleasant stimuli that was similar to that of controls and reduced the viewing time of these stimuli to the same extent as controls. In contrast, while PJ showed similar hedonic appreciation and ratings of wanting for the pleasant stimuli, he reduced viewing time or made no response when presented with these stimuli, thus showing disagreement between self-report and objective assessments of incentive motivation. The tendency to reduce viewing time for stimuli judged as pleasant and wanted may constitute the basic mechanism underlying poor motivation and perhaps social withdrawal and flattened affect associated with globus pallidus damage.

Bipolar disorder (BPD) and Schizophrenia (SCZ) are frequent and severe disorders representing an enormous social, familiar and individual burden, being SCZ the most disabling psychiatric disorder and a major disease characterized by psychosis and cognitive impairment. It is well known that SCZ and BPD are associated with abnormalities in dopamine signaling pathway. Recent data have demonstrated alterations on expression levels of some proteins involved in the modulation of this pathway in brain. It was demonstrated that protein levels of dopamine cAMP regulated phosphoprotein (DARPP-32) is downregulated in dorsolateral prefrontal cortex (DLPFC) of patients with SCZ and BPD when compared with controls. Considering the difficulty to access central nervous system (CNS) tissue, the absence of objective laboratory tests for biomarkers and the bidirectional close relation of nervous and immune systems, this work evaluated the DARPP-32 expression on blood cell subpopulations CD4+ T lymphocytes, CD56+ NK cells, CD19+ B lymphocytes and CD14+ monocytes using flow cytometry assay. Our results shown that the % of DARPP-32 expression is diminished in CD4+ T lymphocytes, CD19+ B lymphocytes and CD14+ monocytes on BPD patients and also decreased in CD4+ T lymphocytes and CD56+ NK cells on SCZ patients. These results shown that the DARPP-32 expression in immune cells corroborate the results obtained from DLPFC of patients with BPD and SCZ, which might suggest that the DARPP-32 expression on lymphocytes and monocytes could be potential biomarkers to help in the diagnosis of neuropsychiatry disorders.

Aim: To assess autoimmunity in patients with different psychiatric conditions using a wide spectrum of autoantibodies.

Methods: Forty seven cases of schizophrenia, 23 cases of schizoaffective disorder, 16 cases of bipolar disorder and 17 patients with different psychiatric conditions were included. Antinuclear, antithyroidal, antimitochondrial, antismooth muscle and antiendomysium antibodies were detected with indirect immunofluorescence. Enzyme-linked immunosorbent assay was used for measuring antiphospholipid, anticardiolipin (IgM and IgG), antithyroperoxidase (IgG), antitransglutaminase (IgA) and antigliadin (IgA and IgG) antibodies. Rheumatoid factor was determined by latex. Psychotropic treatment, age of onset, disease duration and number of hospitalizations were analyzed. All patients underwent a clinical somatic examination.

Results: No clinical symptoms suggesting known autoimmune diseases were found. Fifty four patients (52.4%) had at least one autoantibody. The most frequent autoantibodies found were antigliadin IgG (30.1%), antismooth muscles (13.6%), antinuclear antibodies (11.7%) and rheumatoid factor (9.7%). Presence of antibodies was influenced by age but not by sex or psychotropics. Even though no significant difference could be found between the 4 groups regarding the presence of each antibody, the mean number of autoantibodies per patient seemed higher in the bipolar group than in the rest of the sample (1.5, p=0.06). Antiphospholipid, where present, seemed to appear late in the course of the illness (32 years, p<0.01). Antismooth muscle antibodies were significantly associated to a high rate of hospitalization (1.4, p<0.01).

Conclusion: These findings support an autoimmune activation in a high number of psychiatric patients. Therefore, new therapeutic strategies including immunosuppressive therapies may be considered.

1. Lee E Wachtel¹, Dr., MD, wachtel@kennedykrieger.org

Aim: This paper reviews the concomitance of catatonia and autism spectrum disorders, including incidence, diagnostic similarities, etiologic theories and treatment modalities, including electroconvulsive therapy. Case examples are included.

Method: A review of the English-language literature on catatonia and autism was conducted, combined with the author’s clinical experience working with two autistic individuals with frank catatonic stupor requiring ECT.

Results: While catatonia is most frequently associated with mood and psychotic disorders, frank diagnosable catatonia has been found in 11-17% of individuals with autism. Significant symptom overlap exists between the two disorders in the domains of motor activity, social interaction, communication and behavior; indeed, both processes may share a common neuronal substrate as well as a shared genetic susceptibility region. DSM-IV-TR catatonic symptoms include motoric immobility and overactivity, negativism and peculiarities of movement and speech, while expanded criteria for catatonia in autism additionally include amotivation, difficulty with task completion, day-night reversal and agitation/excitement. A range of severity exists in catatonia, with some patients developing profound catatonic stupor or malignant catatonia with autonomic instability. Catatonia is readily treatable, with lorazepam and ECT as first-line treatments. However, diagnosis may be delayed in the autistic patient with baseline intellectual disability, behavioral and communicative abnormalities. Similarly, appropriate treatment, especially ECT, may be withheld due to issues surrounding intellectual disability.

Conclusion: Catatonia in autism is not an infrequent occurrence in autism, and its manifestations can be severe. Prompt clinical recognition and treatment of catatonia in autism is imperative, with further research needed in this field.
RESOLUTION WITH DIAGNOSIS AND WELL-BEING OF PARENTS OF CHILDREN WITH AUTISM SPECTRUM DISORDERS

Parents whose child receives a diagnosis of an Autism Spectrum Disorder (ASD) undergo a difficult process, one that requires changes in the expectations and hopes that they had for their child and for themselves as parents. Some parents are successful in revising their representations of the child and themselves in light of the child’s diagnosis and are considered “resolved” with the diagnosis, whereas others have difficulties and are considered “unresolved” with respect to the diagnosis. In our study we interviewed 60 mothers and 60 fathers of children between the ages of 2-17 years with the Reaction to Diagnosis Interview (RDI; Pianta & Marvin, 1993) designed to assess resolution and examined whether resolution status was associated with children’s age, functioning, duration of time since receiving the diagnosis, and/or with parental characteristics including gender, IQ, indices of the Broad Autism Phenotype, and perceived impact on the family as well as perceived responsibility and involvement in childcare. Findings indicated that close to 50% of the parents were classified as resolved and that resolution status was not associated with the duration of time since receiving the diagnosis. Furthermore, resolution was associated only with perceived impact on the family and reported involvement in childcare, in that mothers who were resolved reported on less negative impact on the family and on less (over)involvement compared to unresolved mothers. Thus, even though children with ASD introduce profound challenges to the relationships they form with their caregivers, resolution is possible and appears to have important implications for parental well-being.

In recent years, several authors have highlighted the possible impact of deep brain stimulation (DBS) in Parkinsonian patients on hypersexuality, pathological gambling or drug addiction, sometimes in a context of thymic variations. Very little data exist regarding eating disorders occurring after this surgery. We report the case of 6 Parkinsonian patients, from a cohort of 150 patients followed prospectively before and after DBS surgery, having atypical eating disorders associated with weight gain, 3 women and 3 men (57 years old ± 1.9) with an Parkinson disease duration for 10 years. Each of the patients has psychiatric antecedents (anxiety-depressive syndromes, bipolar disorder, assessed with DSM IV criteria). In four patients, eating disorders occur only in the post-operative period, in two patients an aggravation was assessed. At 3 months after surgery BMI increases of 2.9 kg/m² (± 0.5). Craving for sweet was found in 3 patients, two of them having night awakenings. In all cases the scores at BITE remains unchanged at three months. Atypical eating disorder occur most often in a context of euthymic state except for a patient. These changes in eating behaviour after DBS, ask for the role of stimulation in their occurrence and their relationship with mood disorders.

CORRELATIONS BETWEEN ANOREXIA NERVOSA AND PERSONALITY DISORDERS IN ADOLESCENCE

INSTITUTIONS
1. Bambino Gesu Children's Hospital, Neuroscience Department, Rome, Italy

AUTHORS
1. Santino Gaudio¹, Dr., MD, gaus_s@libero.it

OBJECTIVE: Previous research on the correlation between Eating Disorders (ED) and Personality Disorders (PD) was conducted on samples with a wide age range, mainly consisting of adult subjects, and showed a relationship between the two disorders. The aim of the present study is to evaluate the correlation between Anorexia Nervosa (AN) and PDs in a sample consisting exclusively of adolescents with a short history of disease.

METHODS: In a sample of 80 adolescents (from 16 to 18 years of age) with AN [45 with AN restrictive type (AN-r), and 35 with AN binge-purging type (AN-bp)], diagnosed according to the DSM-IV-TR criteria, and 71 healthy controls, we assessed the presence of PDs, using the Italian Version of the Structured Clinical Interview for DSM-IV Axis II Disorders. Patients with and without PD were compared based on age of onset and two measures of disease severity.

RESULTS: A significant correlation was found between AN and PD in the clinical sample compared to the control group. Out of 80 AN patients, 24 (30%) presented with at least one PD. A significant association was found between AN-bp and BPD. Patients with PD had a higher number of hospitalisations, and an earlier age of onset.

CONCLUSIONS: We found a lower general prevalence of PDs compared to results of research on adults, although we observed the same significant associations between the two subtypes of AN, and the different PDs. AN patients with PD have a more severe AN, as well as an earlier age of onset.

7. Stefano Vicari7, Dr., MD
8. Giuseppe Fariello8, Dr., MD

OBJECTIVE: The decrease of both gray matter (GM) and white matter (WM) in Anorexia Nervosa (AN) is a common finding. However, two aspects are still to be clearly elucidated: which are the critically involved brain regions, and whether the possible region-specific decrease of GM and WM is primary or secondary to AN. In order to elucidate these two aspects, cerebral morphometric images of adolescent inpatients with AN-restrictive type (AN-r) were examined.

METHODS: High-resolution, T1-weighted magnetic resonance imaging (MRI) was performed in 11 inpatient girls with AN-r (mean age: 15.2; SD 1.7), without psychiatric comorbidity, and in 11 healthy controls (mean age: 15.5; SD 1.9). Images were preprocessed with SPM2 according to the optimized Voxel Based Morphometry method, and statistically analyzed.

RESULTS: A significant decrease in GM concentration was found in the right and left medial cingulate cortex, and in the right and left precuneus. The decrease in these regions was not found to be significantly correlated with the duration of AN-r. No significant decrease was found in WM.

CONCLUSION: The decrease of GM concentration in the right and left medial cingulate cortex, and in the right and left precuneus, which furthermore is not correlated with the duration of the disease, suggests that these areas have a role in AN pathophysiology. The absence of a significant WM decrease may be due to the short history of the disease. Further research is necessary in order to confirm these findings, and to identify the causes, specific roles, and consequences of such structural modifications.

INTRODUCTION: The endocannabinoid system is a possible target in the treatment of eating disorders. We used positron emission tomography (PET) with [18F]MK-9470 to test whether in vivo binding of this type 1 cannabinoid receptor (CB1R) specific ligand is altered in bulimic and anorectic patients in comparison to healthy volunteers.

METHODS: We investigated 17 female bulimia nervosa patients (BN; age = 23.9±6.9) and 10 anorexia nervosa patients (AN; age = 20.9±3.9) using [18F]MK-9470 PET and volumetric MRI. The control group consisted of 19 women (age = 25.2±8.5). Parametric standardized uptake value (SUV) images reflecting receptor availability were calculated. For regional analysis, SUV values were normalized on the individual global grey matter SUV. Statistical parametric mapping (SPM2; p<0.001) and volume-of-interest (VOI; t-tests, p<0.05) analyses were performed.

RESULTS: No global changes in SUV between groups were detected. In BN patients, regional CB1R availability was significantly increased in the left insular cortex (SPM: +5.0%, pcluster=2.0 10-5 corrected; VOI: p=0.0002) and in the left superior frontal cortex (SPM: +3.5%, pcluster=0.003; VOI: p=0.019). CB1R availability was increased bilaterally in the insular cortex of AN patients (SPM: +5.9%, pcluster=0.0026). Between AN and BN patient groups, no differences in relative CB1R availability were found.

CONCLUSIONS: Regionally, CB1R availability is increased both in bulimia and anorexia nervosa in the insular cortex, a region important in the integration of interoceptive information including primary gustatory information.

Research support: This work was supported by the Research Council of K.U. Leuven (OT/08/38).

3. Maria Psychountaki², Dr
4. Eleutheria Varsou¹, Dr, Md

Aim: The aim of the study was to investigate differences in eating disorder symptomatology between athletes and university students as well as to investigate the factors that increase the risk for a female to develop eating disorder symptomatology.

Material-Method: The EAT-26, BDI, STAI, SPAS were administrated to 60 adult athletes (27 female and 30 male) and 60 non-athletes university students (40 female and 30 male). All subjects were asked to pinpoint on a series of 12 male and 12 female human figures the one that they considered as ideal male and female body as well as the figure that in their mind resembled most their own body. Also the BMI was calculated for every subject.

Results: Male athletes differed from male non-athletes only in the higher scores in the oral control dimension of EAT-26. Female athletes differed from female non-athletes in that they perceived their body as leaner although there was no statistical significant difference between the two group BMI's. Finally the group of women (n=7, 10.4%) that had disturbed eating attitudes (EAT>20) chose leaner ideal female figures and also scored higher in the BDI, STAI trait and SPAS. Younger age (sig=0.04), being an athlete (sig=0.03) and SPAS (sig=0.02) were found in logistic regression analysis to influence significantly the risk for the development of disturbed eating attitudes.

Conclusions: There were only minor differences in eating disorder measurements between the athletes and non-athletes group. A small group of young women that are preoccupied with their physical appearance and are involved in athletic activities seems to run a greater risk for the development of disturbed eating attitudes.

Introduction: In many adiposersone can see a vicious circle in emotional situations of eating, negative emotions followed by eating fits. In our clinic we examined the long term effect on a group being treated by behaviour therapy by psychologists with support of nutritionists with teaching in kitchen and at the table and self-help-group, but without diets Patients and method: All patients of the above mentioned group (n=261) were included with BMI > 30 kg/m2 and BMI 25 - 30 kg/m2 with complicating illnesses. Follow-up examinations by questionnaire (PUDEL and WESTERHOFER) were carried out over a period of 24 months (for 10 moments.)

Results: 58.7% (range 41.6 % - 100%) of the questionnaires were returned. We could observe a significant reduction of weight from 101.7 to 90.8 kg (p=0.000). The cognitive control in the questionnaire showed an increase from 9.15 to 13.59 (of 21) items. The irritation of eating behaviour decreased from 8.2 to 5.6 (/of 16 Items). The perception of hunger decreased from 5.9 to 3.8 (/of 14 Items). All the results were significant.

Discussion: The patients were able to decrease their body weight over a period of 2 years and to decrease their irritation of eating behaviour. Through increased cognitive control, it was possible to change their eating behaviour from unbridled to controlled. We observed, that the perception of hunger remained stable. Thus could the connection between changes of eating behaviour, their triggers and long term weight reduction be proved.

Objectives: The purpose of the study is to reveal factors associated with development of crisis states in young people.

Methods: 2135 crisis calls received by the operators of the Youth Crisis Helpline during one year have been analyzed to evaluate the problems experienced by callers.

Results: The factors associated with crisis included female sex, age above 21, breach with family, domestic violence, interpersonal problems, health/mental health problems, multiple problems.

Conclusion: Recommendations for crisis services providers have been developed.

The first psychiatric intensive care unit (PICU) opened in the early 1970’s in Bronx, New York. This ward was designed to manage patient that did not respond to treatment in open psychiatric wards. Since the 1970’s, the concept of PICU has been used worldwide, as well as in Sweden. There are about 15 PICUs in Sweden but the concept has not been specified by the National Board of Health and Welfare as a public organ. In many county hospitals, both acute and intensive units exist parallel. Therefore, the aim of this study was to describe the core characteristics of PICU in Sweden and to describe the care activities provided for patients admitted to PICU. As the research method, critical incident technique was used. In the study, eighteen caregivers at a PICU participated by completing a semi-structured questionnaire. Additional, in-depth interviews with three nurses and two assistant nurses also constitute the data. After a qualitative analysis of the content four categories were identified that characterise the core of PICU: the dramatic admission, protests and refusal of treatment, escalating behaviours and temporarily coercive measure. Care activities for PICU were also analysed and identified as controlling - establishing boundaries, protecting - warding off, supporting - giving intensive assistance and structuring the environment. Finally, the discussion put focus on determining the intensive aspect of psychiatric care which has not been done in a Swedish perspective before. PICU were interpreted as a level of care as it is composed by limited structures and closeness in care.

Issue: In Iran the higher vulnerability of women combines with stigma against women drug users reduced their access to harm reduction services. Setting: The first Harm Reduction center for women in Iran was funded by welfare organization established in South of Tehran where people with lower socioeconomic level and higher rate of drug use lives.

Project: We provide VCT for HIV, NEP, MMT, and condom distribution free of charge. Outcomes: 214 Drug use women have received our facilities. 48% were married. Only 11% own home, 13% were homeless, and 19% lived with their relatives or friends. Among the cases 64% use Crack, 20%opium, 10% heroin. 12% inject drugs and 19% digests drugs. 50% use drugs 2-3 times and 16% use more common. 53% use drug in the presence of their friends and peers. Only 9% of Drug use women share their syringes, 32% use the clean syringes, and 59% use their own syringes. 80% of them don’t use condom. 81%of the clients have motivation to stop their addiction. 83% of the new clients didn’t know about their HIV status, only 1% of the clients were HIV positive. Barriers includes; lack of knowledge and attitude regarding HIV and using condom, stigma, and lack of social support for the drug use mothers. We should improve our approach to involve other NGOs to provide social support. The lessons learned: Having Structure health care systems to provide integrated care through protecting women drug users' confidentiality, and rights, incorporate women drug users’ needs into guidelines and targets.

Alcoholism has a pronounced effect on people’s mental and physical health. Glutamate dehydrogenase (GLDH) is a linking factor in metabolism of carbohydrates and proteins. Patients with certain forms of neurological and psychiatric diseases have lower GLDH activity in leukocytes and brain. The aim was to define GLDH activity in leukocytes under and after alcohol consumption, what can give us indirect data about protein metabolism in leukocytes. GLDH activity was assed in 238 alcoholics. A blood sample was taken to every subject three times: on admission, after 24 hours and after 7 days. For defining it we developed our own method applying Triton and two freeze-thaw cycles on -20°C and established our own reference leukocyte GLDH from 0.08 - 1.21µkat/g. Leukocyte GLDH activity of those alcohol dependents who had consumed alcohol within last 24 hours prior to measurement was by 75.1% lower, yet not statistically significant. We have confirmed statistically significant fast increase of leukocyte GLDH activity after termination of alcohol intake. After 24 hours, GLDH activity increased for 21.8% (median 31.6%) and 33% (median 52%) after 7 days, yet after a short interval since last alcohol intake, e.g. up to 48 hours, it increased for 32% (median 36%). We estimate that fast increase of low leukocyte GLDH activity after termination of alcohol intake is specific for alcohol addiction. Cessation resulted a significant increase in leukocytes GLDH activity. Therefore, alcohol consumption results in reduction in GLDH activity as well as protein production and consecutively leads to diminished leukocytes protective ability.

Aim: To test the efficacy of long acting surgically implantable formulation of naltrexone (Prodetoxone) vs. oral naltrexone and placebo for relapse prevention to heroin addiction.

Methods: 191 heroin addicts who recently completed detoxification were randomized to a 6 month course of biweekly drug counseling and one of three medication groups: Naltrexone implant (every other month) + oral placebo daily (NI+OP) (66 subjects), Placebo implant (every other month) + Oral naltrexone (PI+ON) (50 mg/day) (63 subjects), and double placebo (implant and oral) (PI+OP) (62 subjects). Medications were administered under double-dummy/double-blind conditions. Urine drug testing and brief psychiatric evaluations (depression, anxiety, anhedonia, and craving for heroin) were done at each biweekly. Oral medication compliance was evaluated using a urine riboflavin marker.

Results: 237 patients were asked if they would be interested in participating, 207 met the study entrance criteria, 195 gave informed consent and 191 were randomized. Survival analysis revealed a significantly greater retention in NI+OP group compared to two other groups (p<0.01). At the end of six months 77.3% of patients of NI+OP group had not relapsed compared to 36.4% in PI+ON group and 18.8% in PI+OP group (p<0.001). No differences in the number of heroin positive urines or either one of psychometrics between groups were found. The number of side effects was limited with no difference between groups.

Conclusion: Long acting sustained release naltrexone implant is safe and more effective than oral naltrexone and placebo for treatment retention and relapse prevention to heroin dependence.

Aim: Most patients suffering from schizophrenia achieve worse results than healthy controls in tests measuring attention. The studies show that among the patients suffering from schizophrenia, about 50% abused psychoactive substances. The data concerning the impact of substance abuse on attention in schizophrenia are inconsistent.

The objective of this study was to examine continuous attention differences between subjects with and without a dual diagnosis.

Methods: A group of 80 patients with schizophrenia were examined. 40 of them never used illicit drugs, the other 40 also received a diagnosis of addiction to psychoactive substances. The group with a comorbid addiction was examined after 6 weeks of detoxification and treatment in a therapeutic community. Continuous Performance Test was applied to for the neuropsychological assessment. The CPT-IP version of this test was used. The patients were presented 450 stimuli in three groups.

Results: No statistically significant differences were found between two groups when they had to omit the identical pair stimuli (finger-up). The same happened in case of false alarms stimuli. However statistical significance appeared when the patients had to react to random stimuli. This part of the test was performed better by the group of schizophrenic patients without addiction.

Conclusions: The above inconsistence of the results may be due to the complexity of attention deficits. It is possible that the impacts of psychoactive substances may be different on the mechanism responsible for reaction to the sequence of experimentally important stimuli than to for ignoring those stimuli, which originally were defined as unimportant.

CHRONIC HEROIN AND COCAINE ABUSE LOWERS SERUM CONCENTRATIONS OF THE NERVE GROWTH FACTOR AND BRAIN-DERIVED NEUROTROPHIC FACTOR

INSTITUTIONS
1. Catholic University Policlinico Gemelli, Psychiatry, Rome, Italy

AUTHORS
1. Valerio Ricci¹, Dr, MD, valerioricci28@libero.it
2. Francesco Angelucci¹, Mr, MD
3. Massimiliano Pomponi¹, dr, MD
4. Gianluigi Conte¹, Mr, MD
5. Pietro Bria¹, Mr, MD

Aims: Neurotrophins are a class of proteins that serve as survival factors for CNS neurons. In particular, nerve growth factor (NGF) plays an important role in the survival and function of cholinergic neurons while brain derived neurotrophic factor (BDNF) is involved in synaptic plasticity and in the maintenance of midbrain dopaminergic and cholinergic neurons. Our aim was to identify possible change in serum neurotrophins in heroin and cocaine users.

Methods: In the present study, we measured by enzyme-linked immunosorbent assay (ELISA) the NGF and BDNF levels in serum of three groups of subjects: heroin-dependent patients, cocaine-dependent patients and healthy volunteers.

Results: We found that BDNF was decreased in heroin users whereas NGF was decreased in both cocaine and heroin users.

Conclusions: These findings suggest that NGF and BDNF may play a role in the neurotoxicity and addiction induced by these drugs. In view of the neurotrophin hypothesis of schizophrenia the data also suggest that reduced level of neurotrophins may increase the risk of developing psychosis in drug users.

**Objective:** This is a semi-experimental research carried out to determine the effectiveness of the psychiatric nursing education provided for nurses who work in a psychiatric hospital.

**Method:** The research was carried out with 59 nurses who work in Manisa Mental and Nervous Diseases Hospital. The nurses who volunteered to the education and attended more than 80% of the courses, took part in a 152-hour education program that was arranged to the literature (1,2,3).

**Results:** While average knowledge score of the nurses pre-psychiatric nursing education was 61.79±15.59, it rose to 77.40±5.97 post-teaching, and this difference in scores was also statistically significant (p<0.01).

**Conclusion:** In conclusion, it was found out that psychiatric nursing education provided for the nurses enhanced knowledge and work motivation at work and thus, the gained knowledge and skills increased the nurses' awareness of evaluating the changes in ward-atmosphere. In line with this conclusion, it is suggested that continuous education programs with similar content on psychiatric nursing and its practices are provided especially for the nurses working with psychiatric patients.

3. Vesile Aycan Baskaya², Mrs.

**Objective:** The study was designed to analyze the burden of caregivers of stroke patients and the factors affecting the burden.

**Method:** This descriptive research was conducted at Turkey Izmir Ataturk Education and Research Hospital, Clinic for Neurology with the participation of 80 caregivers. The data was collected by Introductory Information Form and the Caregiver Burden Inventory (1,2).

**Results:** The average scores of the Caregiver Burden Inventory sub scale were in the order of; time-addiction burden (15.31±4.67), developmental burden (8.19±4.46), physical burden (6.88±3.93), social burden (5.55±4.40), emotional burden (3.44±2.25) and the total burden average score was determined to be 39.36±13.83. A statistically meaningful relationship between the time caregivers spare to their patients and the average sub-scale score of time-addiction burden has been determined (p<0.05).

**Conclusion:** In accordance with the aforementioned results, it has been concluded that taking care of a family member in need is perceived as a task and responsibility in Turkish society. Parallel to this, caregivers are not aware of their burden throughout the process and have difficulty in expressing the hardships they experience.

THE DEVELOPMENT AND IMPLEMENTATION OF NATIONAL STANDARDS FOR INTEGRATED CARE PATHWAYS IN SCOTLAND

INSTITUTIONS
1. NHS Quality Improvement Scotland, Edinburgh, United Kingdom

AUTHORS
1. Mark Fleming¹, Mr, mark.fleming@aapct.scot.nhs.uk

NHS Quality Improvement Scotland (QIS) has published National Standards for Integrated care Pathways (ICPs) in 5 mental health conditions. QIS will utilise the ICP model as a means to develop, improve and monitor the quality for those using and providing mental health services. Consultation with service providers and users underpins development of the standards, set in 4 main areas: 1. Process standards: describe the foundations that must be in place and the key tasks which affect how well ICPs are developed in a local area. 2. Generic care standards: describe the interactions and interventions that must be offered to all people who access mental health services. 3. Condition-specific care standards: build on the generic care standards and describe the interactions and interventions offered by mental health services to people with a specific condition. 4. Service improvement standards: measure how ICPs are implemented and how variations from planned care are recorded and acted on. Emphasis of development and implementation of the ICPs lies with NHS Boards to ensure they are developed with local ownership. To ensure accreditation by QIS, the local ICPs must incorporate the national standards and evidence improvement in the quality of care provided. To aid development and implementation of ICPs an electronic toolkit has been developed containing the standards, evidence summaries, ICP development methodology and additional support materials. National ICP coordinators will facilitate the implementation of the ICP standards.

A ROAD MAP FOR SUCCESS: MODELS FOR EDUCATING ETHNIC MINORITY NURSES IN SUBSTANCE ABUSE AND MENTAL HEALTH SERVICES IN THE UNITED STATES OF AMERICA

INSTITUTIONS
1. American Nurses Association, Minority Fellowship Program, Silver Spring, United States
2. Case Western Reserve University, Frances Payne Bolton School of Nursing, Cleveland, United States
3. University of Pittsburgh, Pittsburgh, United States
4. Wayne State University, Center for Health Research, Detroit, United States

AUTHORS
1. Janet Jackson¹, Ms., janet.jackson@ana.org
2. Faye Gary², Dr., PhD, fgary@case.edu
3. Willa doswell³, Dr., PhD
4. Hossein N. Yarandi⁴, Dr., PhD, yarandi@wayne.edu

Aim: The Minority Fellowship Program (MFP) has designed a blueprint that has proven successful for the education of ethnic minority nurses at the doctoral level. The focus of the Fellowship is on preparing expert educators, researchers, and clinicians who will provide substance abuse and mental health services disorders detection, prevention, and treatment.

Methods: The methods that are described in this paper include recruitment, retention, the statistics study group, mentoring, partnerships with minority communities, tutoring, intensive winter and summer institutes, micro/mini seminars, teleconferences, and personal and career counseling. The Fellows are responsible for providing evidence of their success every six months. Stipends and tuition assistance are provided during designated periods during the year. Fellows are able to select the college or university of their choice. A National Advisory Committee that is comprised of experts in substance abuse and mental health nursing provides oversight for the program. The Logic Model is the framework that underlies the evaluation process, which includes summative and formative data.

Results: The ethnic minority Fellows graduate with their PhD degrees, and make significant contributions in substance abuse and mental health in the world community. They become leaders in research, education, practice, and health policy. One of the key findings related to the success of the program is its longevity.

Conclusion: The MFP is one of the most successful programs in the United States for educating ethnic minority nurses at the doctoral level in substance abuse and mental health disorders detection, prevention, and treatment.

A SUSTAINABLE MENTAL HEALTH SYSTEM IN RURAL SUB-SAHARAN AFRICA: THE ROLE OF NGO PARTNERSHIP - A CASE FOR UGANDA

INSTITUTIONS
1. Butabika National Mental Hospital, Psychiatry, Kampala, Uganda

AUTHORS
1. Fred Kigozi, buthosp@infocom.co.ug

The contribution of mental health burden on the global burden of disease is known to be significant world over. The situation is even worse in the developing world where both human and financial resources are grossly limited amidst the increasing burden of disease caused by poverty, civil strife and recently the HIV/AIDS pandemic. The mental health problems, while common in urban areas, the rural folks have not been spared either, with massive displacements as internally displaced persons especially in Africa. Access to specialized mental health care in many parts of Africa is still limited to developed few and mainly in urban areas. In an attempt to improve equity and access to mental health services, many countries have adopted policies and systems that bring on board other key players particularly in disadvantaged rural areas by the traditionally known caregivers such as NGOs. The paper will discuss the various contribution of Non-governmental Organizations to sustainable mental health care delivery in Africa based on WPA Zone 14 experience.

IMPACT OF COERCION ON SHORT-TERM OUTCOME OF INPATIENT PSYCHIATRIC CARE

INSTITUTIONS
1. School of Health and Medical Sciences, Psychiatric Research Centre, Örebro, Sweden

AUTHORS
1. Lars Kjellin, Dr., PhD, lars.kjellin@orebro.se

Objectives Conflicting results regarding the impact of coercion on outcome in psychiatric inpatient settings have been reported. The aim of the present study was to explore the association between short-term outcome of inpatient psychiatric care and number of days of involuntary detention.

Methods 110 involuntarily admitted or detained patients at four Swedish psychiatric clinics were interviewed within five days from admission and at discharge or after 3 weeks of care. Outcome was classified as improved or not improved based on patients’ self-reports (subjective outcome) and change in GAF scores (assessed outcome).

Results The median number of days of involuntary detention was 28 (range 1 - 311). Days of involuntary detention were not associated to subjective or assessed outcome. Patients reporting they had been well treated (respected and listened to) by the staff had significantly less number of days of involuntary detention than other patients (median 28 vs. 31 days).

Conclusion This is the first outcome study to use days of involuntary detention as a measure of coercion. The results support the findings of some previous studies, indicating that coercion is not associated to subjective or assessed short-term outcome of inpatient psychiatric care.

Domestic violence is a major social, mental health and public health problem. It crosses ethnic, racial, cultural, age, religious, national origin, sexual orientation, and socioeconomic lines. The aim of this research is to develop and standardize an evidence-based, culturally sensitive bi-lingual (Arabic/English) measure of risk for domestic violence to be used in health service settings. The research was conducted in Dearborn, Michigan, where the population includes large numbers of immigrants. As is the case with all batterers, abusers of immigrant women use cultural values and norms as powerful weapons in controlling their victims’ behavior. To date, there is no domestic violence risk assessment tool that is culturally appropriate for Arab Americans. Focus group methodology was used to address the aim of the study. Five focus group meetings were conducted in the community to determine culturally specific domestic violence risk factors. Major variables considered by the focus group participants to be critical in the assessment of risk factors included the following: religious beliefs, lack of family support, economic situation, social norms, immigration status, legal rights and English language skills. A culturally appropriate risk assessment tool was developed based on the recommendations of the focus group participants and literature review. The scale was pilot tested in the community and will be used with Arab American women.

PROBLEMS AND OPPOSITION TO CONSTITUTION OF MENTAL HEALTH CENTERS IN MONTENEGRO

INSTITUTIONS
1. Center For Mental Health, Kotor, Serbia and Montenegro

AUTHORS
1. Aleksandar Macic1, Dr, filstem@cg.yu
2. Milka Novovic1, Dr

In recent years, with the support of the Stability pact for south-east Europe, and following the example of the EU countries, there has been developed a new concept of mental health care. It should be carried out by newly opened centers for mental health. Goal of the work is to set forth numerous problems which considerably slow down development of these modern approach to mental health care, as well as solutions to them. Problems in the realisation of the project, have been stated and classified in the discussion together with explanation of their causes and consequences:
- unadjusted or non-existent accompanied legal acts;
- negligence of bureaucracy, resistance in other social services;
- prejudices and opposition of „official” psychiatry and of professionals in mental health institutions;
- insufficient education and shortage of trained staff
- lack of understanding and resistance in a wider community;
- financial problems.

Further on, methods have been stated for finding „less painful” solutions to these problems. This experience is probably similar to those in all countries in transition and should help that the same mistakes would not be made in further development of communal psychiatry. This work contains recommendations how to prevent and avoid these obstacles and may be useful in those places where development of such approach to mental health care just being planned.
When I started my psychiatric residency in the U.S.A. in 1962, there were said to be 750,000 patients in mental (state) hospitals in the U.S.A., 50% of all hospital patients. Now there are about 200,000 patients in those hospitals, but there are close to 1,800,000 prisoners in the country, as opposed to 300,000 earlier. Psychiatric services in the developing countries in Asia, Africa and South America suffers from enormous manpower constraints. As opposed to the norm of 100-150 psychiatrists per million population in developed countries in Western Europe and North America, developing countries average 1 to 4 psychiatrists per million. However, contrary to the expectation, in spite of affluence and advantageous manpower situation, Western countries do not necessarily provide a more optimal level of care, particularly for severe mental disorders. The mental health services in a country like the U.S. are very variable, with large pockets being ill-served. It is accordingly emphasized that, while paying attention to making progress, developing countries should uphold their advantages, and should heed own priorities and philosophy. They should not blindly follow the West, so as to avoid their mistakes. (There is compelling evidence, for example, that the outcome of severe mental illness is more favourable in developing countries.) We must not lose sight of our advantages - of indigenous psychosocial therapeutic approaches and the traditional social support and values and family ties, increasingly eroded in the developed world.
THE RELATIONSHIPS BETWEEN CHRONIC PAIN AND CHRONIC PTSD IN CROATIAN WAR VETERANS

Aims/Objectives: Recent research suggests that chronic PTSD and chronic pain frequently co-occur and that similar mechanisms may exist for maintaining both conditions. The high comorbidity between these disorders has been postulated as being due to either shared vulnerability or mutual maintenance. The authors analysed relationships between chronic PTSD, chronic pain and somatization in Croatian war veterans.

Methods: The 184 veterans who were treated at the Clinic for Psychological Medicine during year 2007 were selected as the sample for this study. On the base of interviews, medical records and different questionnaires (Mississippi Scale for combat-related PTSD, Mc Gill Pain Questionnaire, Pain Outcomes Questionnaire, Brief Pain Inventory, SCL-90) the authors analysed the relationships between chronic pain, chronic PTSD and somatization.

Results: Patients suffered from different chronic pain syndromes. We found statistically significant positive correlation between PTSD symptoms and pain intensity. Patients with chronic PTSD had significantly higher total pain scores as well as affective and sensory pain components compared to the patients without PTSD. Affective component of pain were significantly correlated with the level of PTSD symptoms. Increased levels of PTSD experiencing symptoms were associated with increased pain level and pain-related disability. Comorbid depressive symptomatology was correlated with higher pain scores.

Conclusion: We assume that chronicization of stress disorder has a similar pattern of genesis in relation to acute stress stimuli as well as chronic pain syndrome in relation to peripheric painful stimulus. PTSD may promote chronic pain through a complex interaction between biological, psychological and behavioural mechanisms.

Aims: The Brazilian Obsessive-Compulsive Spectrum Disorders Research Consortium includes 7 Brazilian sites. Its interests include collaborative research spanning over areas of OCD: phenotype; genetics; neuropsychology; neuroimaging and therapeutics. The objectives of this paper are: to present the implementation of the consortium and the initial clinical results.

Methods: 458 patients with DSM-IV OCD criteria were evaluated with: Structured Clinical Interview for DSM-IV; Yale-Brown Obsessive-Compulsive Scale; dimensional YBOCS; Yale Global Tic Severity Scale; Beck Depression and Anxiety Inventories; University of São Paulo Sensory Phenomena Scale; Brown Assessment of Beliefs Scale; Social Evaluation Scale; Trauma History Questionnaire; Post Traumatic Stress Disorder Checklist; and Peritraumatic Dissociative Experiences Questionnaire.

Results: 54% were female and 84.9% were Caucasian. The mean age was 34.6 (+12.5) years, with compulsions starting earlier (13.7, +8.5) than obsessions 14.2 (+8.5); 71% of the subjects had previously used an antiobessive medication, and 64.3% had received psychotherapy. The most common OC symptoms were: symmetry (88.0%), contamination-washing symptoms (71.8%) and aggression (65.9%). The mean YBOCS score was 24.3(+7.8) while the DYBOCS score was 20.2 (+6.2). At least 66.6% of the patients presented sensory phenomena and 34% presented Tics. The most frequent psychiatric comorbidities were Major Depression (70.3%), Generalized Anxiety Disorder (33.6%), Social Phobia (28.4%) and Simple Phobias (27.1%).

Conclusion: The CTOC initiative was able to gather relevant data from a large number of OCD patients from different parts of Brazil, with a very comprehensive assessment battery. These data have heuristic value for etiological, clinical, genetic and treatment studies, in an effort to better understand the OCD heterogeneity.

3. Eleutheria Varsou¹, Prof, MD
4. Andreas Rabavilas², Prof, MD

Aim: The aim of the present study was to investigate possible differences between OCD patients with and without OCPD.

Method: 76 patients with OCD were interviewed during their first visit in a university psychiatric outpatient clinic. The clinical diagnosis of OCD and OCPD was confirmed with the use of SCID-II. Thirty-five (46.1%) of the 76 OCD patients were found to suffer also by OCPD. Each patient completed the EPQ, LOI, ZDS, WI, STAI, HDHQ and LCB.

Results: The OCPD group scored higher than the non OCPD group in the LOI hoarding (p=0.001), meanness (p=0.02), irritability/moroseness (p=0.001), rigidity (p=0.001), regularity (p=0.001) and punctuality (p=0.001) subscales, the WI for hypochondriasis (p=0.003), the HDHQ acting out (p=0.02), criticism of others (p=0.009) and introversion of hostility (p=0.05) subscales while according to LCB it had more external locus of control (p=0.009). Discriminant analysis showed that the LOI hoarding (sig=0.001), meanness (sig=0.001), irritability/moroseness (sig=0.001), rigidity (sig=0.001), punctuality (sig=0.001) subscales score as well as the HDHQ acting out subscale (sig=0.001) score could differentiate the two groups.

Conclusion: The major finding of this study was that, beyond obsessionality, the main difference between OCD patients with and without OCPD was the higher probability of acting out behaviour.

OC-27-04
EXPERIENCES OF TRAUMA AND PTSD IN ARAB AMERICAN IMMIGRANT WOMEN

INSTITUTIONS
1. Wayne County, Health and human services, Detroit, United States
2. Wayne State University, College of nursing, Detroit, United States

AUTHORS
1. Anahid Kulwicki¹,², Dr., DNS, kulwicki@oakland.edu

Background: Arab American populations show high prevalence of Post Traumatic Stress Disorder (PTSD) that may be culturally based. Ongoing exposure to trauma and immigration status may determine unique presentation of symptoms. Paucity of research makes examination of PTSD in this population critical.

Objectives: To assess trauma through the Arabic version of Post Traumatic Stress Disorder Scale (PDS) and identify how trauma exposure affects mental and emotional well-being of Muslim Arab immigrant women.

Study Design: The PDS scale was translated, pilot tested and administered to 636 immigrant Muslim women along with demographic and migration information.

Results: The most frequently reported stressors were military combat (76%) and accidents/explosions (58.6%). Middle-Eastern immigrant women showed frequent traumatic events that may constitute physical and mental-health risk.

Conclusions: Accurate assessment of immigrant’s mental health remains critical. We recommend mental health counselors use validated, reliable instruments and pay attention to particular multilateral traumas when assessing immigrant women.

MEASURING RESILIENCE IN OIF/OAF VETERANS

INSTITUTIONS
1. Case Western Reserve University, Psychiatry, Cleveland, United States
2. Cleveland VAMC, Psychiatry, Cleveland, United States

AUTHORS
1. Matig Mavissakalian1,2, Dr., MD, mrm6@case.edu

Resilience is associated with optimal coping and successful adaptation. At the Center for Stress Recovery a 10 week psychoeducational workshop (Rwas designed specifically to promote resources and to increase resilience in OIF/OEF (Iraq and Afghanistan veterans) seen at the Cleveland VAMC. This presentation aims to assess if RReached its purported goal and to explore if initial resilience level has differential effects outcome.

The Connor-Davidson Resilience Scale (CD-RISC) is a 25-item self rating measure of resilience that has a range from 0-100, with higher scores reflecting greater endorsement of hardiness, dynamism, self efficacy, patience, humor in the face of adversity, altruism and/or spirituality. The CD-RISC was administered to the first, consecutive 34 individuals entering RRand readministered to the 23 completers. Analysis of data using repeated measures ANOVA and effect sizes (ES) revealed statistically (p=.005) and clinically (ES=0.53) significant improvement in CD-RISC scores in completers. 11/34 individuals dropped out. Median (63) split comparisons showed that lower initial resilience was associated with greater attrition (8/17 vs 3/17,p=0.67) and that improvement in CD-RISC scores was more marked in the lower initial resilience subgroup of completers (ES=0.77).

Conclusion: The psychoeducational classes improved resilience to a significant degree in OIF/OEF veterans. The differential effects of initial resilience on outcome highlight the potential usefulness of measuring resilience in future efforts, both at the individual and policy making levels, to improve the retention of OIF/OEF veterans who have the most to gain but tend to drop out from an effective, time limited psychosocial intervention.

SECONDARY IMMUNE DEFICIENCY AS A RISK FACTOR FOR DEVELOPMENT OF PROLONGED COURSE OF POSTTRAUMATIC STRESS DISORDERS

INSTITUTIONS
1. Mental Health Research Institute, Russian Federation

AUTHORS
1. Valentina Nikitina1
2. Tamara Vetlugina1
3. Elena Epanchintseva1

Objective: To develop assessment methods allowing prognosis of transition of neurotic disorders in persons after stressful events into chronic course.

Methods: 96 men have been examined - participants of military actions in Caucasus with PTSD. According to type of course and duration of disease patients have been divided into 2 groups: 1-acute-subacute course of PTSD, duration of disease not more than 3 years (46 persons); 2-prolonged course of PTSD, duration of disease 3 and more years (50 persons). We have identified structure of secondary immune deficiency (ID) and somatic health in examined groups. Laboratory diagnosis of ID was conducted with standard methods.

Results: Clinical signs of secondary ID have been revealed in 58.6% of examined of group 1 and in 78.6% - group 2. During comparison of incidence of somatic diseases pathology of various systems in group 1 has been noticed in 63.2% of combatants, in group 2, somatic pathology has been revealed in 100% of combatants. Significant differences have been identified between parameters of the immunity in patients of examined groups. Immune status of combatants with prolonged course of PTSD as compared with the group 1 was characterized by lower values of number of T-lymphocytes -CD3, natural killers -CD16; higher values of number of B-lymphocytes and activated T-lymphocytes HLADR, level of circulating immune complexes.

Conclusions: Revealed differences of indices of immune status between examined groups of combatants, presence of clinical signs of ID and somatic pathology allow considering complex of these factors as predictors of prolonged course of PTSD.
MODEL OF REHABILITATION OF PTSD PATIENTS IN BESLAN.

INTRODUCTION: Tragic events in Beslan have become not only the cause of death of more than three hundred children and adults, but also provoked plenty of PTSDs in former hostages, their relatives and witnesses of this terrorist act. Additional difficulties were connected with the lack of local professionals in PTSD treatment and the absence of co-ordination into the work of local and non-local specialists.

METHOD AND RESULTS: The model of psychological rehabilitation of PTSD patients was developed on the basis of our own experience while working with the victims of terrorist act in Beslan. The first step is organizing of trainings for local specialists to provide a qualified help for PTSD patients. The next step is to create a satisfactory motivational level of a victim’s family for psychotherapeutic work. The future activities are strictly oriented on the whole family and includes at least four specialists: two psychologists and two psychiatrists, two of whom should be local professionals and two others are high qualified international supervisors. The next step includes the mutual discussion of both clinical and psychological findings, including diagnosis, and development of the individual rehabilitation program both for PTSD patient and the members of his/her family as a result. Further rehabilitation work is provided by local specialists and international professionals take part in rehabilitation activities only by periodical supervising.

CONCLUSION: This model was useful in rehabilitation work in Beslan and helped to overcome a number of difficulties while working with PTSD patients and their families.
THE ATYPICAL PSYCHOSES: FROM PSYCHOPATHOLOGY TO NEUROBIOLOGY

5. Gerald Stöber⁵

Insights into the polymorphic and bipolar symptomatology of the atypical psychoses are of particular importance for the basic sciences as well as for clinical practice. Bipolar, catatonic, behavioural, and first rank symptoms are analysed regarding their heuristic value and under nosological considerations (Verhoeven and Tuinier, The Netherlands; Cetkovich-Bakmas, Argentina). The stability of interrater reliability of psychiatric symptoms and changes of hallucinations and delusions over lifetime in patients with psychotic disorders were followed up over 21-33 years in a large series of cases (Pethö, Hungary). Results of a family and twin study on cycloid psychoses point to a significantly reduced morbidity risk in families compared to manic depression and unsystematic schizophrenias (Jabs, Germany). In periodic catatonia, a familial subtype of unsystematic schizophrenias, the major gene locus has actually been localized to chromosome 15q15 in two independent genome scans (Stöber, Germany).

THE CONCEPT OF ATYPICAL PSYCHOSES IN VIEW OF DIFFERENTIATED PSYCHOPATHOLOGY

INSTITUTIONS
1. Institute of Neurosciences, Favaloro Foundation, Argentina

AUTHORS
1. Marcelo Cetkovich-Bakmas¹

The concept of “atypical” psychoses dates from Kraepelin’s dichotomy and refers to endogenous psychoses which could be assigned neither to schizophrenic psychoses nor to manic depressive illnesses due to their atypical clinical pictures. Within the differentiated psychopathology along the lines of Karl Leonhard the problem of “atypical” psychoses was accommodated by the idea that there might be an independent group of endogenous psychoses in addition to schizophrenias and manic-depressive illness, i.e. the cycloid psychoses. Main features of cycloid psychoses are a phasic remittent course without residual states and a bipolarity of the polymorphous clinical syndromes which occur in three characteristic subforms, the anxiety-happiness-psychosis, confusion psychosis and motility psychosis. The cycloid psychoses have to be differentiated mainly from the unsystematic schizophrenias which also show bipolarly structured polymorphous clinical syndromes, but run a progradient course with exacerbations and incomplete remissions leading to residual states of varying degrees of severity. Clinical studies have shown that a reliable clinical differentiation of cycloid psychoses and unsystematic schizophrenias is possible if a comprehensive exploration is carried out by a sufficiently trained examiner.
CYCLOID PSYCHOSES AND PRADER-WILLI-SYNDROME

INSTITUTIONS
1. Vincent van Gogh Institute for Psychiatry, Venray, The Netherlands

AUTHORS
1. Willem M.A. Verhoeven
2. S. Tuinier

Aims/Objectives: Prader-Willi syndrome (PWS) is a disorder that results from the absence of a normal paternal contribution to the chromosome 15q11-13 region, due to either a paternal deletion or an uniparental maternal disomy (UPD). Apart from the behavioural problems associated with food seeking and intellectual disability per se, PWS carries the risk for a broad array of psychopathology. Concerning psychotic disorders, an association has been suggested with UPD.

Methods: A total of 28 PWS patients were referred for neuropsychiatric evaluation because of long lasting or recurrent behavioural problems and psychotic symptoms. Tentative formal psychiatric diagnoses were established according to the ICD-10.

Results: All but two patients (insufficient data) had a history of mood instability paralleled by fluctuating behavioural problems. With respect to actual psychopathology, 7 met the criteria for a bipolar affective disorder. In the other 21, the symptomatology included emotional turmoil, anxieties, irritability, confusion, (rapid) mood swings, hallucinatory experiences and paranoid ideation, with a variable intensity and subacute onset. Therefore a diagnosis of cycloid psychosis was considered most appropriate. In 17 patients the etiology was UPD and in 4 a deletion. Three were genetically confirmed and in four a clinical diagnosis was made only.

Conclusions: The psychosis was preceded by affective instability for many years suggestive for an atypical bipolar disorder with an increase of obsessive rituals and the presence of cycloid symptoms in the acute phase.

INTERRATER RELIABILITY OF PSYCHIATRIC SYMPTOMS AND CHANGES OF HALLUCINATIONS AND DELUSIONS OVER LIFETIME IN PATIENTS WITH PSYCHOTIC DISORDERS: RESULTS OF A 21-33 YEAR FOLLOW-UP

Our prospective study (n = 276; female patients n = 222; normal control persons n = 54) “Budapest 2000” started in 1967-1976. For the purpose of this study, the diagnostic status of our target population was defined by one of the eight unique nosological categories representing the middle level of hierarchy in the Leondharean classification system. The same population was followed-up by participation of the principal investigator and a “blinded control” psychiatrist in 1997-2002 [patients available at follow-up = 125 (56.3%); available controls = 38 (70.4%)]. The two independent diagnosticians summarized their diagnostic decisions by making a definitive or a combined or a less specific Leondharean diagnosis or using the label “normal control person” concerning each person investigated. Predictive validity of the hebephrenias, group of normal persons and of schizophrenias proved to be valid categories, with diagnostic stability of 0.94, 0.91, and 0.93, for the three groups, respectively. In addition, bipolar manic-depressive psychoses and cycloid psychoses were also valid (diagnostic stability of 0.77 and 0.76, respectively). Unipolar depression was valid (diagnostic stability = 0.84) only by forming a “nosological family” based on diagnostic stability and on current status and clinical presentation during the period preceding the follow-up with regard to other mood-congruent disorders and outcome-diagnosis “normal control”. Validity of systematic paraphrenias (diagnostic stability = 0.69) was in the moderate range. Division of schizophrenias in “systematic versus non-systematic” nosological categories was inconclusive; the categories of affect-laden paraphrenia, periodic catatonia and systematic catatonia could not be confirmed reliably in this study. In a subsequent analysis based on a large scale symptomology we aimed at validation of catatonia taking in consideration special symptoms and signs.

A CONTROLLED FAMILY STUDY AND A SYSTEMATIC TWIN STUDY ON CYCLOID PSYCHOSES

INSTITUTIONS
1. University of Würzburg, Department of Psychiatry, Psychotherapy and Psychosomatics, Würzburg, Germany

AUTHORS
1. Burkhard Jabs

Cycloid psychoses represent a clinical category which can be reliably differentiated from schizophrenic and affective psychoses regarding symptomatology and course. To further clarify aetiological and nosological questions concerning cycloid psychoses a controlled family study and a systematic twin study were undertaken. In the family study, all living and traceable adult first-degree relatives of 45 cycloid psychotic, 32 manic-depressive and 27 control probands were personally examined by an experienced psychiatrist blind to the index proband’s diagnosis. Age-corrected morbidity risks were calculated using the life-table method. Relatives of cycloid psychotic patients showed a significantly lower morbidity risk of endogenous psychoses than relatives of patients with manic-depressive illness but did not differ significantly from relatives of controls.

In the twin study, 22 twin pairs with cycloid psychotic index twins were systematically recruited in the psychiatric hospitals of Lower Franconia. After establishing the diagnoses of the respective cotwins by an independent experienced psychiatrist concordance rates were compared. They did not differ significantly between the 11 monozygotic and the 11 dizygotic pairs.

Both studies suggest a subordinate role of hereditary influences in the aetiology of cycloid psychoses. The results point out that cycloid psychoses have to be distinguished from manic-depressive illness as well as from schizophrenic psychoses regarding clinical genetic aspects, and that cycloid psychoses therefore could be integrated neither into a spectrum of schizophrenic psychoses nor into a spectrum of affective disorders.

PERIODIC CATATONIA: PHENOTYPE AND NEUROBIOLOGICAL FINDINGS

INSTITUTIONS
1. University of Würzburg, Department of Psychiatry, Psychotherapy and Psychosomatics, Würzburg, Germany

AUTHORS
1. Gerald Stöber

Gjessing and Leonhard described periodic catatonia as a distinct catatonic psychosis, which has been underestimated over decades. The central syndrome in periodic catatonia consists of qualitative psychomotor disturbances in both, a hyperkinetic and akinetic pole. Psychomotor excitement gives way to iterations and stereotypes, grimacing and parakinesia. On the other pole, prominent symptoms are akinetic negativism as well as distorted stiff movements, mask-like facies or posture stereotypes. In most cases acute psychotic attacks are accompanied by hallucinations and delusions. In remission there remains a distinct mild to severe catatonic residual state with psychomotor weakness of facial expression and diminished incentive. Videos of patients suffering from motility psychoses contrasted by those exhibiting periodic catatonia are presented with discussion of differential diagnoses and therapeutic strategies.

Periodic catatonia (MIM 605419) is genetically mapped to chromosome 15q15 in two independent genome-wide linkage scans on a total sample of 16 multiplex pedigrees. Parametric as well as haplotype analysis were consistent with the assumption of an autosomal dominant inheritance with reduced penetrance, as reflected by a morbidity risk of ~27% for first degree relatives. Linkage and haplotype analysis in three exceptionally large pedigrees linked to chromosome 15q15 disclosed a refined critical region. Thus, the findings on clinical phenotypes of catatonia speak in favour of a nosological classification of catatonia. As a general conjecture in the endogenous psychoses, clinical differentiation creates nosology, and these biological foundations will forge ahead insights in the aetiology.

COLLABORATIVE CARE OF DEPRESSION - TRANSLATION OF AN EVIDENCE-BASED MODEL INTO MULTIPLE PRIMARY CARE SETTINGS ACROSS MINNESOTA

INSTITUTIONS
1. Mayo Clinic, Psychiatry and Psychology, Rochester, United States
2. Mayo Clinic, Family Medicine, Rochester, United States

AUTHORS
1. Mark D. Williams¹, Williams.mark@mayo.edu
2. John Wilkinson², wilkinson.john@mayo.edu

This workshop will make the case for a change in the way depression is managed and the value of a collaborative model. We will then describe a translational clinical experiment of providing an incentive to primary care practices across the state of Minnesota in the United States towards implementation of this evidence-based model. Outcome data from the first group of several clinics and data specific to one primary clinic at Mayo will be presented. Time will be available for questions and dialogue with the audience.

TRANSLATION OF COLLABORATIVE CARE FOR DEPRESSION INTO OVER 20 DIFFERENT HEALTH PRACTICES

INSTITUTIONS
1. Mayo Clinic, Psychiatry and Psychology, Rochester, United States

AUTHORS
1. Mark D Williams¹, Dr, MD, Williams.mark@mayo.edu

Aims and Objectives:
1. A review of current barriers to effective treatment of depression
2. The DIAMOND model and creating a climate of change
3. Specific focus on role change for participating psychiatrist
4. Outcome measures and early data of the initiative

Depression is a common and costly problem and access to mental health treatment in most of the US is poor. New models are needed to better address depression for both the primary care providers and the mental health professionals. A collaborative model of care has significant support for efficacy¹.

Methods:
The Institute for Clinical Systems Improvement (ICSI) was able to pull together the major insurance carriers in the state of Minnesota to reach agreement that they would reimburse for a model of collaborative care in select clinics across the state. In order to receive this new source of income, each practice had to make significant changes in their practice model.

Results:
Six clinics (including one within the Mayo system) agreed to participate in the first wave of the project and to share outcomes. Every six months a new set of clinics is added over a five year period with plans to adjust the model as the initiative progressed.

Conclusions:
This model has wide applicability and provides a way to address depression in a population where there are limited resources. Outcomes will be reviewed along with lessons learned about this mechanism of introducing practice change.

References
COLLABORATIVE CARE FOR DEPRESSION — LESSONS LEARNED AT ONE MAYO PRIMARY CARE CLINIC

INSTITUTIONS
1. Mayo Clinic, Family Medicine, Rochester, United States

AUTHORS
1. John Wilkinson¹, wilkinson.john@mayo.edu

Aims and Objectives:
1. Description of practice model and limitations before collaboration.
2. Change process and new roles
3. Outcome measures specific to Mayo and data from first six months

Depression is a common and costly problem and access to mental health treatment in most of the US is poor. New models are needed to better address depression for both the primary care providers and the mental health professionals. A collaborative model of care has significant support for efficacy.¹

Methods:
Mayo formed a team of providers in primary care involving nursing, administration, and psychiatry to participate in a series of meetings with teams from other institutions around development of this model in each institution. Several barriers were common to many of the groups and will be reviewed. An internal study of the clinical intervention was created to attempt to better monitor outcomes.

Results:
The initial outcomes included patients screened appropriately, those responding to treatment as documented by the Patient Health Questionnaire, and recruitment data. Other outcomes will include changes in access to mental health and utilization differences by patients managed in this model as compared to those in practice as usual.

Conclusions:
The care management model in the DIAMOND project is be a powerful model to assist in reaching a population of patients with depression.

PSYCHOSOMATICS IN PSYCHIATRY AND THE CROSS-CULTURAL POINT OF VIEW OF POSITIVE PSYCHOTHERAPY

INSTITUTIONS
1. Int. Academy for Positive and Cross-Cultural Psychotherapy, Wiesbaden, Germany

AUTHORS
1. Nossrat Peseskian¹, Prof. Dr., MD, PhD, nossrat@peseskian.com
2. Shridhar Sharma¹, Prof. Dr., MD, PhD
3. Francois Biland¹, Dr.

This workshop is to systematically and comprehensively present the pathway of Positive Psychotherapy and its implications for psychosomatic medicine and mental health, in such a way that specialists in the different fields are involved in information sharing and practice.
Aim: One essential aim of this workshop is to systematically and comprehensively present the pathway of Positive Psychotherapy and its implications for psychosomatic medicine and mental health, in such a way that specialists in the different fields are involved in information sharing and practice.

Method: The transcultural approach, which is central to Positive Psychotherapy (since 1968), describes the relativity of the concepts of illness and their dependence on the culture areas in which they are found. These observations and considerations have encouraged us to develop a model which attempts to place health, rather than sickness, at the core.

Result: Therapeutically, we offer an efficacious five-stage short therapy which stresses activation of the patient’s indwelling therapeutic capacities. In other words, the patient is not only the sufferer of his illness, but also is employed as a therapist himself. The success rate showed that as a rule there was either a cure or considerable improvement after just a short time (6 to 15 sessions). Check-ups after a year generally showed that the success had continued. Presentation of awarded quality assurance.

Conclusion: The current situation in psychiatry and psychosomatic medicine and psychotherapy calls for the development of procedures that are both economical and efficient. In addition to the technical questions related to therapeutic procedure, content-related questions, concerning the criteria with regard to which the existing conflict is to be described and worked through, acquire importance.

Aim: The concept of psychosomatic disorders is based on the basic principle of “Mind Body dualism” and is an elusive interplay of psyche and soma; in which both health and disease are strongly influenced by psychological and sociocultural factors.

Method: The concept implies the existence of a class of disease, in which the application of psychological approach provides information of high etiological relevance and where somatic symptoms can be successfully treated by methods effective in treating psychic symptoms. How these symptoms develop in cultural context and how they respond by psychological intervention is interesting phenomena.

Result: Recent research findings also suggest that Biology and Culture act on one another as the conditioning parameters of neurocultural information. In this process culture conditions and stimulates biology, while biology conditions and makes culture possible. Various psychotherapeutic techniques have been used in treating psychosomatic disorders. In the present paper, the role and usefulness of Positive Psychotherapy is explained.

Conclusion: In the Positive Psychotherapy, emphasis is not on illness but on man and his capacities, and wherein Stress is given on available potential of each persons to enable him to cope effectively with his problems.
PSYCHOSOMATICS AND POSITIVE AND TRANSCULTURAL PSYCHOTHERAPY IN CONSULTATION-LIAISON-PSYCHIATRY IN A GENERAL HOSPITAL IN SWITZERLAND

INSTITUTIONS
1. Int. Academy for Positive and Cross-cultural Psychotherapy, Wiesbaden, Germany

AUTHORS
1. Francois Biland¹, Dr.

Objectives
Many Swiss therapists, nurses and physicians are interested in transcultural problems of foreign or immigrated patients but they often run the risk to do too much and they burn out.

Methods
A pilot project "Migrant Friendly hospital; against racism and discrimination in the hospital" was started in the General Hospital of Olten (reference 1). Language courses are offered right at work for the staff and for the patients the opportunity of translation from more than 20 languages; even instantly through telephone. The Positive and Transcultural Psychotherapy was integrated in the daily work of C-L-Psychiatry and the ambulatory rehabilitation of cardiac patients.

Results
The Positive and Transcultural Psychotherapy turned out to be very effective and successful. It has deeply and positively changed the therapeutic approach of the hospital staff. Embedded in oriental and other stories (reference 2) this approach was very well accepted by immigrated and Swiss patients.

Conclusion
This presentation will be an illustration of the practical value of the Positive and Transcultural Approach - a method developed by Prof. Peseschkian in the last 40 years. The theory will be presented by Prof. Peseschkian in his lecture.

4. Emmanuelle Jouet⁴, Dr, Ph.D., ejouet@ch-maison-blanche.fr

Emilia is an EU framework 6 action research focused on mental health and social inclusion in eight European demonstration sites over 54 months.
The project aims to enable service users who experienced psychosis to enter training and employment. Attitudinal changes, the acquisition of new knowledge and skills, and locally collaborative work are called for. Presently users have been already recruited to the project. Following initial assessment and planning they are taking training modules (e.g. recovery, relapse prevention, dual diagnosis, assertiveness, engagement in research).
The added value of the project lies not only in enabling users to lead an ordinary life, but in facilitating the service to become a life long learning organisation.
Evaluating the outcomes, economic costs, participants’ perspectives (users and providers) is of central importance within an action research geared towards sharing and learning from the findings while the project evolves.
To achieve this purpose the evaluation of the project entails both quantitative and qualitative aspects, with repeat measures. Furthermore, the evaluation investigates both individuals through time series, and the service organisations through an organisational case study to understand and impact on both key components of the project.
The workshop will focus on the evaluation of the first phase of the project, the rationale for selecting the tools, the logistics of data collection on eight sites, the main findings and what we can learn from them.

QUALITATIVE RESEARCH AS A TOOL IN THE DEVELOPMENT OF LIFE LONG LEARNING BY THE DEMONSTRATION SITES AND BY SERVICE USERS WITHIN EMILIA: AN EU ACTION RESEARCH PROJECT IN MENTAL HEALTH AND SOCIAL INCLUSION

INSTITUTIONS
1. Tampere University, Nursing, Tampere, Finland
2. Anglia Ruskin University, Health and social care, Cambridge, United Kingdom

AUTHORS
1. Marja Kaunonen¹, Marja.kaunonen@uta.fi
2. Shula Ramon², s.ramon@anglia.ac.uk

Emilia is an EU framework 6 action research project focused on mental health and social inclusion for people experiencing serious mental illness in eight European demonstration sites, over 54 months.
The added value of the project lies not only in enabling users to lead a more fulfilling life, but in facilitating the service to become a learning organisation able to provide more effective user and social inclusion interventions.
The qualitative research aspect of Emilia has concentrated on two aspects:
1. Through documentary analysis, observation of staff meeting and a focus group, an organisation case study is constructed. It is aimed at tracking changes over time in the implementation of the lifelong learning strategy within the learning organisations.
2. Through users’ self report and interviews with a smaller number of key informants, users perspectives are recorded about desired changes in their lives and how these are achieved, obstacles to achieving these changes and steps to overcome them, and to evaluate the degree to which individual mental health service users are attaining social inclusion through this process.
As Emilia is an action research, we are disseminating the findings and our analysis back to the demonstration sites, to assist the learning process of these organisations.
The process of carrying out the data collection, the major findings from the baseline data obtained from the demonstration sites, and issues in dissemination of findings to the demonstration sites will be presented.
EMILIA: QUANTITATIVE RESEARCH ELEMENT

INSTITUTIONS
1. Institute of Psychiatry, Service evaluation, London, United Kingdom

AUTHORS
1. Tamara Shaw1, t.shaw@mdx.ac.uk
2. Richard Gray1

Evidence (Grove, 2005) highlights the difficulty people with serious mental illness have in finding employment and/or meaningful activities, and its cost to society, resulting in social exclusion. Through the quantitative element of the research we will investigate the degree of the impact of lifelong learning (EMILIA training) in helping people find work/meaningful occupation and whether it is cost effective. Our primary hypothesis is that lifelong learning will increase the number of people with severe mental illness who are in employment, compared to the previous year. Secondary hypotheses are that lifelong learning will increase the time spent in employment and/or education and training, and improve quality of life.

Service users recruited into the study will be asked to complete two quantitative survey measures in order to collect outcome data on employment status, use of mental health services, amount of training received and quality of life. They will be assessed at baseline (before commencing the EMILIA training) and then at one year and two year follow up. Data on the economic costs of the training interventions will be estimated from locally specific information from the demonstration sites.

Preliminary findings from the baseline data assessment will be presented.

BUILDING THE PATHWAY READINESS EVALUATION TOOL TO ACCESSING LIFELONG LEARNING AND EMPLOYMENT FOR PEOPLE WITH MENTAL ILLNESS ACROSS EUROPE

INSTITUTIONS
1. EPS Maison Blanche, Laboratoire de recherche, Paris, France

AUTHORS
1. Emmanuelle Jouet1, ejouet@ch-maison-blanche.fr
2. Tim Greacen1

The paper describes a new instrument for measuring obstacles and facilitators to accessing lifelong learning and employment for people with enduring mental illness across Europe, and the processes involved in developing it. At four key points in the process of putting into place parallel lifelong learning projects for this population at 8 European sites, qualitative questionnaires and interviews reveal progressively deeper layers of obstacles to accessing training and meaningful activities. High unemployment rates at certain sites create a highly competitive job market which disadvantage this group. Laws fixing incentives or obligations for employers, occupational health constraints and issues around obtaining diplomas and accreditation can often become obstacles. Institutionally, the lack of integrated rehabilitation schemes and the barriers between social and health care systems create multiple problems for users, ranging from contradictory information through to difficulties accessing training funding.

Disabilities allocations, sheltered workshops, social support and housing, create a sense of security and stability that works against training and competitive employment. Users and their families fear the economic and psychological consequences of losing current security. Obstacles appear at all sites, with discrimination and stigma playing a major role in accessing real-world training, employment and other social activity.

Finally, at the individual level, the nature and severity of the psychiatric disability can constitute an obstacle in itself.

OUT AND ABOUT: AN UPDATE ON LESBIAN AND GAY MENTAL HEALTH

INSTITUTIONS
1. CSP, San Francisco, CA, United States

AUTHORS
1. Gene Nakajima¹, Dr., MD, Gnakajima@alumni.stanford.org

In this workshop, 4 psychiatrists will address diverse topics in gay and lesbian mental health. Dr. Olson will speak about gay people over 55 who live in the US. He will present findings from a series of biographical interviews, which he used to construct a model for successful identity formation of the aging gay man. Dr. Carrion, a Puerto Rican, will explain his work with children who experience interpersonal violence and discuss how this research can inform the psychological consequences and treatment of hate crimes against gay youth. Dr. Cabaj, a Polish American, will review how homosexuality in and of itself is not a mental illness and is not psychopathological. Men and women who are gay, lesbian or bisexual, however, may have specific behavioral health issues that must be appreciated to treat them effectively. Dr. Nakajima, a Japanese American, will speak about damaging and unscientific diagnoses in ICD-11 that relate to homosexuality. He will outline changes that are needed for ICD-11 and DSM-V to bring them in line with current psychiatric thinking and clinical practice with gay people.

UPDATE ON LESBIAN AND GAY MENTAL HEALTH

INSTITUTIONS
1. Private Practice, Des Moines, United States

AUTHORS

The Graying of Gay Men in the United States: A Model for Successful Identity Formation

Aims and objectives:
When gerontologists study the elderly, they study heterosexuals; when gay rights advocates discuss homosexuals, they mean young homosexuals. Although about 3 1/2 million gay, lesbian, bisexual and transgender people over the age of 55 live in the United States (1), little is known about them, even in the gay community. Older gay men have lived the majority of their lives during periods of active hostility and oppression toward homosexuality where being openly gay was not adaptive. Some now are finding that they must again hide their sexuality in order to access services necessitated by their aging.

Methods:
This research was conducted through biographical interviewing described by Levinson (2), using a research interview while allowing subjects to tell their unique story as it has evolved over the years. Because of the difficulty in accessing these subjects and the depth of the interviews, only about 20 subjects will be interviewed. A survey of 200 subjects will also be discussed.

Results:
Preliminary findings from these interviews will be presented.

Conclusions:
Using these interviews, a model for successful identity formation of the aging gay man will be constructed. It will also serve to raise awareness of the extent and diversity of this population.

EVALUATING GAY YOUTH EXPOSED TO HATE CRIMES AND TREATMENT IMPLICATIONS

INSTITUTIONS
1. Stanford University, Psychiatry, Stanford, CA, United States

AUTHORS
1. Victor G Carrion, MD, vcarrion@stanford.edu

AIMS: This presentation will apply research in youth with interpersonal violence and a diagnosis of posttraumatic stress disorder (PTSD) to gay youth with a history of hate crimes.

METHODS: Research from 100 youth with PTSD symptoms who have been evaluated with salivary cortisol, brain neuroimaging (via sMRI and fMRI), behavioral and cognitive instruments will inform the assessment of gay youth with history of hate crimes. In addition, a multi-modality structured manual that has been developed for youth with a history of trauma will be discussed in terms of its applicability for the treatment of youth exposed to hate crimes.

RESULTS: Gay youth exposed to hate crimes and who develop symptoms of PTSD may have limbic and prefrontal cortex abnormalities of structure and function (Carrion et al 2007; Carrion et al 2008). Exposure and insight-oriented treatment into the importance of cues on behavioral symptoms may impact the functional impairment in these kids.

CONCLUSIONS: Hate crimes are an example of interpersonal violence and as such can produce symptoms of PTSD in youth. These symptoms are treatable with a variety of modalities that include cognitive behavioral therapy, insight-oriented therapy, exposure, education and self-efficacy training.

A RESEARCH REVIEW AND AGENDA FOR FUTURE RESEARCH FOR GAY, LESBIAN AND BISEXUAL POPULATION

INSTITUTIONS
1. University of California, San Francisco, Psychiatry, San Francisco, United States

AUTHORS
1. Robert P Cabaj, Dr., MD, bob.cabaj@sfdph.org

Homosexuality is considered a normal variation of human sexual expression, on a continuum with heterosexuality and bisexuality. Gay men, lesbians and people who are bisexual—though not having a mental illness due to sexual orientation and of itself—have specific mental health issues and concerns that need to be addressed for the delivery of the best possible behavioral health care. Research over the years has identified areas of concern such as higher rates of affective disorders, suicide-related behaviors, and substance abuse. There are many areas for future research such as the effects of cross-cultural issues, impact of same-sex marriage on mental health, parenting effects and so on. This presentation will review the current research and future directions and was a paper that was presented to the American Psychiatric Association’s Committee to revise the DSM.

Reference:
ARE WE STILL DIAGOSING HOMOSEXUALITY AS A MENTAL ILLNESS? PROPOSED REVISIONS FOR ICD-11 AND DSM-V

INSTITUTIONS
1. CSP, San Francisco, CA, United States

AUTHORS
1. Gene Nakajima, Dr., MD, GNakajima@alumni.stanford.org

Aims: To understand the history of how homosexuality was regarded as a mental illness and continues to viewed as pathologic by many psychiatrists worldwide. To understand current diagnostic controversies and problematic and unscientific diagnoses like Ego-dystonic Sexual Orientation, Sexual Maturation Disorder and Sexual Relationship Disorder in ICD-10. To understand the treatment implications of these diagnoses for gays and lesbians. To understand how political concerns may override scientific concerns in the inclusion of these diagnoses to ICD-11.

Method: Literature review of diagnoses related to homosexuality through MEDLINE and PSYCH-INFO

Results: These three diagnoses are almost never used in the scientific literature. Research on these diagnoses is almost non-existent. There is no scientific validity to these diagnoses and national psychiatric societies should advocate that they not be used in ICD-10 and eliminated from ICD-11.

Conclusions: As progress continues toward the creation of ICD-11 and DSM-V in 2011, suggestions for changes will be discussed. Because political rather than scientific concerns may have driven the inclusion of these diagnoses, the importance of lobbying for changes through scientific channels will be discussed. Particular revisions in DSM-V, especially relating to the diagnosis, sexual disorder NOS, will also be discussed.(1)

WORKING THROUGH THE TRAUMA OF THE HOLOCAUST IN A BI-NATIONAL ASSOCIATION

INSTITUTIONS
1. IPAMH, Israel

AUTHORS
1. Henry Szor

The Israeli-Polish Association for Mental Health (IPAMH) was established simultaneously in Poland and in Israel May 2000. Its goals express mainly a deep and shared commitment of Polish and Israeli psychiatrists to the victims of the Holocaust. It defined as its central goals to investigate the roots of and the harm caused by racial and ethnic hatred and anti-Semitism and other forms of racial prejudice. We undertook to further the above goals and to contribute to the improvement of mental health care in our two countries and to develop and strengthen mutual contacts between mental health care professionals in Poland and Israel and thus to contribute to international mutual understanding and to contribute to an enlightened and tolerant society. In order to achieve those aims the association established a framework of intensive and continuous bi-national meetings, which allowed for a creation of deep personal relations between the participants, thus laying the basis for a common learning and an emotional working through of the historical past, the conflict and its implication on present and future. This workshop will demonstrate different aspects of the ongoing process. We will stress in our contributions the importance of bi-national working together when dealing with a conflict, which is so deep and complex. Our work might serve as an example or even a model for other conflicts between nations as well as between any other opponents who are immersed in a deep and difficult conflict which otherwise might be experienced as insoluble and not allowing forgiveness.
IN THE FACE OF ANTI-SEMITISM: THOUGHTS OF THE POLISH PSYCHOTHERAPIST

AUTHORS
1. Bogdan de Barbaro¹
2. Barbara Józefik¹
3. Lucyna Drozdowicz¹
4. Krzysztof Szwajca¹

Members of the Polish-Israeli Association for Mental Health established at the Faculty of Psychiatry CMUJ in Krakow have been meeting for a few years and have formed a group of a special kind. While presenting the dynamics of this group, it is worth observing the controversies that create the axis of discussion at the heart of the association. Should the association work in the form of a club with well-defined boundaries, or whether the idea of expanding the group and its outside activity is more important? Should the meetings have a self-instructive and educational character, or whether the thread of “inner talk” inspired by group meetings is more essential? Annual meetings with a group of psychiatrists and psychologists from Israel, in turn, make one consider and think about an optimal structure for the group: should the Israeli-Polish dialogue be deepen, or maybe tripartite Polish-Jewish-German meetings would be more profound and offer greater development and progress. The heated discussion in Poland that had been incited in connection with the publication of Professor J.T. Gross’ work on Polish anti-Semitism after the war has become an additional stimulus to ask questions about national mythology and its dark sides. It has demonstrated the basic meaning of Polish narrations, often contradictory, concerning Polish attitudes and stances toward Holocaust. While sharing their thoughts on the above mentioned issues, the authors refer to their personal experiences.

A MULTI-GENERATIONAL PERSPECTIVE OF THE GROUP PROCESS, IN A GROUP OF THE ISRAELI POLISH MENTAL HEALTH ASSOCIATION (IPMHA)

INSTITUTIONS
1. Haemek Medical center, Psychiatric Department, Afula, Israel
2. Technion, Faculty of Medicine, Haifa, Israel

AUTHORS
1. Ilana Kremer¹,²

The Israeli-Polish Mental Health Association (IPMHA) operates as a part of the psychiatric associations of both countries. One meeting takes place every year, alternately in Poland and Israel, with a core of participants from both sides that attended all the meetings, and a number of participants who only participated in some of the meetings. I will bring the narrative of the group, as well as a discussion about the overt and covert motivations of the participants, including the coordinators, and a description of the group's process. In addition I will bring in details vignettes from four group meetings.

The group is multi-generational. I will show that it is possible to identify among the participants various mental processes of working through the trauma of the Holocaust, where the difference most noticeable is between generations. I would like to suggest that an intra-psychic and interpersonal process of Forgiveness, with its complexities and difficulties, takes place, in a different way in persons of different generations.
TREATMENT MODELS FOR BIPOLAR DISORDER: HELPING PATIENTS PAST THE BUMPS IN THE ROAD

INSTITUTIONS
1. Case Western Reserve University School of Medicine, Psychiatry, Cleveland, Ohio, United States
2. University of Michigan, Psychiatry, Ann Arbor, Michigan, United States

AUTHORS
1. Martha Sajatovic¹, Professor, MD, martha.sajatovic@uhhospitals.org
2. Frederic C. Blow², Professor, PhD, fredblow@umich.edu
3. Amy M Kilbourne³, Dr, PhD, amykilbo@med.umich.edu

Illness outcomes for individuals with bipolar disorder (BD) are complicated by comorbidities, treatment non-adherence, and issues related to care delivery. Individuals with complicated BD have greater functional disability, higher health care costs and higher suicide rates than individuals with uncomplicated BD. This workshop will discuss the implementation of effective treatment models for bipolar disorder with a focus on complexity issues. Comorbidities occur disproportionately in persons with BD and health care costs from medical and substance use disorders can be up to 40%-70% higher than psychiatric care for this group. Interventions that address comorbidity can improve outcome and reduce costs. In spite of growingly sophisticated treatments for BPD, nearly one in two individuals with BD do not benefit from drug treatments because of poor medication adherence. However, there is evidence suggesting that collaborative treatments stressing psychoeducation, the development of illness self-management, and ongoing relapse prevention can improve adherence. Finally, improving outcomes for individuals with BD in routine care requires system-level efforts that can be implemented across different providers and settings. Examples of potentially effective strategies include pay-for-performance models and the application of integrated medical and psychiatric chronic care models. Managing illness complexity requires involvement of individuals with illness, their families, health care providers and health care systems. Evidence-based treatment approaches may improve illness outcomes for individuals with complicated BD.

TREATMENTS FOR INDIVIDUALS WITH BIPOLAR DISORDER AND COMORBID SUBSTANCE ABUSE

INSTITUTIONS
1. University of Michigan, Psychiatry, Ann Arbor, Michigan, United States

AUTHORS
1. Frederic C. Blow¹, Professor, PhD, fredblow@umich.edu

The complexities of comorbidity common among patients with bipolar disorder (BD) present special challenges for mental and physical health care delivery for both the public and private healthcare sectors. For example, approximately 65% of individuals with BD meet DSM-IV criteria for at least one comorbid Axis I psychiatric disorder, and alcohol and drug abuse occur more often with BPD than with any other Axis I diagnosis. Additionally, BD illness severity is strongly correlated with psychiatric and medical comorbidity. However, until relatively recently, research on co-occurring disorders among individuals bipolar disorder has received little attention, despite the unique service needs of this particularly vulnerable population. This presentation will focus on substance use disorders in bipolar populations.

An emerging literature suggests that integrated treatment that addresses both BD symptoms and comorbid conditions can optimize outcomes among bipolar populations that might have had a particularly poor prognosis in the past. Comprehensive and concurrent medical, psychiatric, and substance abuse treatment is known to provide stabilization, education, and self-management while at the same time reducing conflicts between providers, potentially eliminating burden of attending two treatment programs, and reducing financial and other barriers to access and retention.
ENHANCING TREATMENT ADHERENCE AMONG INDIVIDUALS WITH BIPOLAR DISORDER

INSTITUTIONS
1. Case Western Reserve University School of Medicine, Psychiatry, Cleveland, Ohio, United States

AUTHORS
1. Martha Sajatovic¹, Professor, MD, martha.sajatovic@uhhospitals.org

A major obstacle to good outcome among individuals with bipolar disorder (BD) is discontinuation of medications. This presentation will summarize the current literature on prevalence and consequences of non-adherence in BD populations, measurement of adherence, risk factors for non-adherence, general and psychoeducational interventions to enhance treatment adherence among bipolar populations, and suggests future directions in approaches with respect to treatment adherence enhancement. There is an urgent need for greater understanding of interventions that can be implemented in real-world settings that address patient, provider/system, and environmental/social factors that are critical to treatment adherence. A growing literature suggests that it is possible to enhance treatment adherence among patients with BD. The most positive evidence for the improvement of medication adherence among patients with BD comes from specific psychosocial interventions used in conjunction with pharmacotherapies. It has been suggested that improved treatment adherence is at least a partial component of the observed positive outcomes of psychoeducational approaches among bipolar populations. Many individuals with BD remain relatively uninformed regarding their illness, creating potential barriers to optimal treatment adherence, and limiting self-management skills. A collaborative care model in which individuals are active participants in their own care decisions can potentially optimize choice of interventions intended to improved medication treatment adherence.

IMPROVING OUTCOMES: MANAGING UNWANTED CO-TRAVELERS IN BIPOLAR DISORDER

INSTITUTIONS
1. University of Michigan, Psychiatry, Ann Arbor, Michigan, United States

AUTHORS
1. Amy M Kilbourne¹, Dr., PhD, amykilbo@med.umich.edu

Medical conditions are often referred to as „unwanted co-travelers” in bipolar disorder, but are prevalent and contribute to substantial morbidity and mortality. Cardiovascular disease (CVD) is a common cause of mortality in patients with bipolar disorder, in part because of behavioral, treatment, and system-level factors that exacerbate CVD risk. Despite the existence of effective medications for managing CVD-related risk factors (e.g., hypertension, hyperlipidemia, diabetes, obesity), outcomes for these conditions remain suboptimal among patients with bipolar disorder. However, interventions targeting the unique CVD-related risks in patients with bipolar disorder have not been developed. We describe how bipolar disorder can exacerbate CVD-related risk factors and morbidity, and review practical guidelines for providers and patients. We also review where gaps in medical care exist, and discuss emerging strategies to enhance quality of care (e.g., the Chronic Care Model). We also describe a brief intervention (Bipolar Care Model) designed to improve outcomes, coordinated care, and health behavior change in the context of bipolar disorder. The intervention's three core components include: 1) self-management behavioral sessions for patients addressing the reduction of CVD risk factors through symptom control and behavior change (diet, exercise), 2) care management to promote patient behavior change and coordinated care, and 3) implementation of practice guidelines for providers on management of CVD risk factors in patients with bipolar disorder. Lessons learned from the implementation of the intervention, including clinical pearls, practical patient education strategies, and guidance for monitoring and improving control of CVD-related risk factors will be discussed.
W-08

CULTURE, SOCIETY, AND MENTAL HEALTH: RECONCILING GAY IDENTITIES IN THE 21ST CENTURY

INSTITUTIONS
1. UCSF, Dept. of Psychiatry, San Francisco, United States

AUTHORS
1. Howard C. Rubin¹, Dr., MD MSHS, hrbuin@pacbell.net

Four psychiatrists from diverse backgrounds, will address cross-cultural and clinical issues relating to gay identities. Dr. McIntosh a Canadian will describe his experience working in Toronto with LGBT (Lesbian, Gay, Bisexual, and Transgender) immigrants and the interaction of settlement issues, cultural conflicts and sexual/ gender identity issues. Also the particular issues of refugees claiming asylum from persecution on the basis of sexual orientation/gender identity will be raised. Dr. Hall will speak on how psychiatry and related clinical and academic disciplines hold conflicting models of sexual variation and identity, which complicate the interpretation of research studies and compromise clinical work. He reviews relevant literature from anthropology, sexology, and psychiatry and presents a comparative framework for understanding male homosexual identity. Dr. Nakajima, a Japanese American, will speak about the formation of gay identities of East Asians living in North America. Howard Rubin, MD a Jewish American will highlight the struggle to reconcile gay identity with traditional religious values. He will present a psychotherapeutic case of a Catholic man struggling with his faith and with his sexuality.

SEXUAL ORIENTATION AND GENDER IDENTITY AND IMMIGRATION

INSTITUTIONS
1. University of Toronto, Department of Psychiatry, Toronto, Canada
2. Mount Sinai Hospital, Department of Psychiatry, Toronto, Canada
3. Toronto East General Hospital, Department of Psychiatry, Toronto, Canada

AUTHORS
1. Christopher A McIntosh¹²³, Dr., MSc, MD, FRCP, chris.mcintosh@utoronto.ca

AIM: To explore how sexual orientation and gender identity issues impact the mental health of immigrants to a large North American city.

METHODS: The author will describe his experiences working with lesbian, gay, bisexual and transgendered (LGBT) immigrants and refugees from different countries who are settling in Toronto, Canada, a city that is strongly supportive of both gay rights and the rights of immigrants to maintain their cultural values.

RESULTS: LGBT immigrants report typical psychosocial stressors related to "coming out" but also a sort of "double cross-cultural" conflict in which they may feel excluded from mainstream Canadian culture on the basis of their immigrant status but also from their culture of origin on the basis of their sexual orientation or gender identity.

CONCLUSIONS: The case material presented suggests further investigation into the mental health needs of this population is warranted.
RECONSIDERING HOMOSEXUAL IDENTITIES IN CROSS-CULTURAL PERSPECTIVE: VIEWS FROM SEXOLOGY, ANTHROPOLOGY, AND PSYCHIATRY

INSTITUTIONS
1. UCLA Semel Institute of Neurosciences, Psychiatry, Los Angeles, United States

AUTHORS
1. Timothy M Hall1, Dr, MD PhD, mccajor@earthlink.net

Aims: Accurate models of human sexual variation and patients’ self-understanding are important for both psychotherapy and community health interventions, but clinical psychology and psychiatry, academic sexology, and other disciplines currently hold several conflicting models of sexual identity.

Methods: The author conducted anthropological fieldwork in the Czech Republic since 1999, including semi-structured interviews with 46 homosexual and bisexual Czech men, two surveys in 2002 (n=144) and 2005 (n=133) of attendees at gay bars in Prague, and anthropological analyses of gay-oriented literature and informal discourse among gay men in Prague and three US cities.

Results: Many current models of homosexual identity assume a linear, step-wise development of sexual identity towards an ideal based on contemporary Western urban populations, not supported by this or other recent comparative studies. Many respondents in this study do not demonstrate exclusively same-sex behavior (e.g. they marrying heterosexually); do not consider sexual orientation as a primary component of their social identity; and do not form homosexual communities above the level of sexual or friendship networks—though some do so.

Conclusions: In contrast to many current models, we must attend to the interplay of psychological, cultural, and social factors—specifically, how the distinct axes of sexual orientation, sexual behavior, and sexual identity interact with local social conditions. Not only are non-Western homosexual identities and communities not developing towards a 1990s-Western type, but Western homosexual identities themselves are continuing to change in response to ongoing social changes.

DEVELOPMENTAL AND MENTAL HEALTH ISSUES IN GAY EAST ASIAN AMERICANS

INSTITUTIONS
1. CSP, Psychiatry, San Francisco, United States

AUTHORS
1. Gene Nakajima1, Dr., MD, gnakajima@alumni.stanford.org

Aims: To understand how East Asian gay men and lesbians in North America experience racism within mainstream gay communities and homophobia (anti-gay prejudice) within Asian American communities. To understand how East Asian gay men develop their own sense of ethnic and sexual orientation identities.

Method: Literature review and clinical data.

Results: Many East Asian Americans come from Korean, Japanese, and Chinese families which emphasize traditional Confucian values of family or collective good over individual needs. Those ideals conflict with mainstream North American culture's emphasis on individualism. East Asian Americans may be more circumspect about their sexual orientation and less open to their families and ethnic communities than European Americans. They may also have difficulties in their relationships with partners from the dominant culture as values concerning sexual orientation may conflict. Because they may view aspects of their traditional cultures as anti-gay, they may fail to integrate them into their identities. Conversely, racism in mainstream gay and lesbian communities impacts the formation of integrated identities in Asian Americans as well.

Conclusion: Understanding how East Asian gay men and lesbians from North America develop their own sense of identity is important in providing culturally competent psychiatric treatment to this population. How gay and lesbian Asian Americans navigate their sexual orientation and ethnic development may also impact their romantic relationships.(1)

WRESTLING WITH THE ANGEL: THE PSYCHOTHERAPY OF A GAY MAN STRUGGLING WITH HIS RELIGIOUS FAITH

INSTITUTIONS
1. UCSF, Department of Psychiatry, San Francisco, United States

AUTHORS
1. Howard C Rubin¹, Dr., MD, MSHS, hrubin@pacbell.net

Objectives: To understand the complex interplay of religion, spirituality and sexual orientation

Methods: Psychotherapeutic Case Presentation and Formulation.

Results: T is a 56 yo gay man and a devout Catholic who is struggling to reconcile his sexual orientation with his orthodox Catholic faith. Although he is well versed in the contemporary perspectives on sexuality within more progressive elements of the Church like the Most Holy Redeemer Parish in San Francisco¹, he finds it extremely difficult to accept a spiritual path not directly blessed by Rome and the Church hierarchy². Through the insights gained in psychotherapy, I have tried to help him forge a more resilient identity that allows him to incorporate the strength of his religious convictions and spiritual beliefs into a more cohesive gay identity.

Conclusion: This case presentation highlights the importance of gay affirmative psychotherapy in helping patients reconcile and integrate conflicting beliefs into an authentic self.

PRINCIPLES AND PRACTICE OF AUTOGeneric TRAINING AND BREATHING RELAXATION

INSTITUTIONS
1. Indiana University School of Medicine, Indianapolis, Indiana, United States
2. South Staffordshire and Shropshire Healthcare NHS Foundation Trust, Burton upon Trent, United Kingdom

AUTHORS
1. Vijoy K Varma¹, Professor, MD, FRCPsych, vijoyv@comcast.net
2. Nitin Gupta², Dr., MD, nitingupta659@yahoo.co.in

The limitations of pharmacological approaches are becoming increasingly apparent, particularly in psychosomatic and neurotic disorders. As such, there is increasing emphasis on non-pharmacological approaches such as yoga, various types of meditation, including transcendental meditation and relaxation techniques, such as autogenic training and breathing relaxation. Furthermore, non-pharmacological treatments have the added advantage of greater acceptance and freedom from side-effects.

This presentation will discuss the literature regarding one such technique, i.e., autogenic training (AT), and give live presentation of its delivery.
AUTOGENIC TRAINING AND BREATHING RELAXATION IN TREATMENT OF NEUROTIC AND PSYCHOSOMATIC DISORDERS

AUTHORS
1. Vijoy K Varma, Professor, MD, FRCPsych, FAMS, vijoyv@comcast.net

The limitations of pharmacological approaches are becoming increasingly apparent, particularly in psychosomatic and neurotic disorders. As such, there is increasing emphasis on non-pharmacological approaches such as yoga, various types of meditation, including transcendental meditation and relaxation techniques, such as autogenic training and breathing relaxation. Furthermore, non-pharmacological treatments have the added advantage of greater acceptance and freedom from side-effects. This presentation will discuss the literature regarding one such technique, i.e., autogenic training (AT), and give live presentation of its delivery.

AT is based on usage of verbal formulas of self-suggestion for relaxation, focusing on a visual formula (the mandala), based on Jung's theory of collective unconscious. The recent revival of AT was brought out by Schultz in 1932. The recent research into AT has examined its efficacy in migraine, insomnia and test anxiety, angina pectoris, asthma, childbirth, eczema, hypertension, infertility, Raynaud's disease, recovery from myocardial infarction, panic attacks and agoraphobic avoidance, trait anxiety and psychosomatic complaints in anxiety and panic disorders. In addition AT has been found useful in psychosomatic illnesses, including tension headache, vascular headache, obesity, neurasthenia, and irritable bowel syndrome. A high profile USSR-USA project in AT and breathing relaxation documented effectiveness of these techniques in hypertension; it also reported improvement in quality of life. In addition, there has been reported enhanced cardiac parasympathetic tone with AT.

In a study, we found autogenic training to be as effective as psychotropic medication in generalized anxiety disorder (Kohli, Varma and Nehra, 2001).

THE PRACTICE OF AUTOGENIC TRAINING

INSTITUTIONS
1. South Staffordshire and Shropshire Healthcare NHS Foundation Trust, Burton upon Trent, United Kingdom
2. Indiana University School of Medicine, Indianapolis, Indiana, United States

AUTHORS
1. Nitin Gupta, Dr., MD, nitin.gupta659@yahoo.co.in
2. Vijoy K Varma, Professor, MD, FRCPsych, vijoyv@comcast.net

Autogenic training (AT) is based on usage of self-suggestion for relaxation. The basic principle is to have the subjects simultaneously attend to i) verbal commands, ii) the relaxation figure, mandala, and iii) a part of the body. The technique is characterized by teaching to remember the sensation of relaxation related to a part of the body, and to connect this with.

In the first sessions, the basis of AT is explained. It useful to emphasize that AT and the mandala are not totally based on any particular religion.

The sessions are performed in groups of 4 to 12. The subjects sit in comfortable deep arm-chairs arranged so that all can have a good view of the mandala which hangs 1 metre above the floor. Their heads lean against the neck-rest, legs are kept slightly apart, hands lie palm down either on the thighs or on the armrests. They are asked to assume a comfortably relaxed position with the so-called „relaxation mask“ (facial muscles relaxed).

In the beginning of the session, the subjects recount how have they been and felt lately. Then, the therapist starts to pronounce the relaxation modules rhythmically, in a commanding but not authoritative tone of medium loudness. The eyes should usually remain open looking at the mandala but can also be closed, if so wished. At the end of the session, the patients are asked about their feelings during the session.

AT can also be practiced at home with a tape recorder and mandela.

HIV AND GAY/BISEXUAL MEN: CHALLENGES FOR THE SECOND QUARTER CENTURY OF THE EPIDEMIC

INSTITUTIONS
1. Mt. Sinai medical center, psychiatry, New York, NY, United States
2. National Institute of Mental Health, psychiatry, Bethesda, Maryland, United States
3. Beth Israel Medical Center, psychiatry, New York, NY, United States

AUTHORS
1. Daniel Garza1, Dr., MD, GARZAD@nychhc.org
2. Sami Khalife2, Dr., MD, sammykhalife@gmail.com
3. Kenn Ashley3, Dr., MD, KAshley820@aol.com

It has been 25 years since the impact of the HIV virus became evident to the medical community. Three psychiatrists from diverse backgrounds will discuss the psychosocial impact of HIV/AIDS which continues to evolve even after the advent of successful anti-retroviral treatments that usually control the effects of infection. Dr. Khalife, a NIMH research fellow from Beirut, Lebanon will speak about how stigma and discrimination play an important role in AIDS psychiatry given their impact upon the physical and mental wellbeing of patients, loved ones, families, and caregivers. The creation of a supportive non-judgmental healthcare environment can combat stigma. Dr. Ashley, an African American, will speak about increases in new HIV diagnoses among Men who have sex with Men (MSM), possible reasons for the rise, and various issues regarding interventions and treatments. Dr. Garza, a Mexican American, will speak about young gay men, born in a world already affected by the virus, who are beginning to bear the brunt of this growing incidence of infection. Access to wireless of forms of communication, support, and intimacy has created a facile and accelerated connection among MSM resulting in unsafe sexual liaisons increasing HIV and other infections.

STIGMA ASSOCIATED WITH HIV AND AIDS

INSTITUTIONS
1. National Institute of Mental Health, Mood and Anxiety Disorders Program, Bethesda MD, United States

AUTHORS
1. Sami Khalife1, M.D., sammykhalife@gmail.com

Aims/Objectives:
To describe the characteristics of HIV/AIDS-related stigma in the US and its impact on individuals and society. To suggest strategies to deal with this public health problem.

Methods:
Literature review of articles and books on stigma associated with HIV and AIDS written since the beginning of the epidemic.

Results:
Stigma, discrimination, and fear in conjunction with denial, feelings of omnipotence, and lack of awareness perpetuate the HIV pandemic. Stigma associated with HIV and AIDS magnifies other stigmas associated with HIV risk behaviors (e.g. bartering sex, drug abuse…). It affects HIV positive individuals and previously stigmatized groups disproportionately affected by HIV (e.g. gay men, sex workers, ethnic minorities…). Stigma and discrimination play an important role in AIDS psychiatry given their impact upon the physical and mental wellbeing of patients, loved ones, families, and caregivers. The creation of a supportive, nurturing, non-judgmental healthcare environment can combat stigma.

Conclusion:
More than two decades after the epidemic began, stigma related to HIV/AIDS still exists. It impacts the psychological and physiological wellbeing of people living with HIV and complicates its prevention and treatment. There is an ongoing need for education and implementation of public health strategies to reduce this stigma.
THE SAME STORY OR A NEW EDITION? THE INCREASING RATE OF HIV INFECTIONS IN MEN WHO HAVE SEX WITH MEN (MSM)

INSTITUTIONS
1. Beth Israel Medical Center, Peter Krueger Center, New York, United States

AUTHORS
1. Kenneth B Ashley¹, Dr., MD, kashley@chpnet.org

AIMS: To present data on the recent increase of new HIV infections and rates of HIV/AIDS in men who have sex with men (MSM), discuss possible causes for this finding, and explore interventions

METHODS: Data on rates of new HIV infections was reviewed, as well as the literature on interventions to address risk behavior—especially among MSM.

RESULTS: MSM have been the largest proportion of AIDS cases in most industrialized countries. The initial interventions promoting risk reduction now appear less effective with increasing rates of new HIV infections in MSM. Recent estimates show increases in HIV/AIDS among MSM in the US and 13 Western European countries (1).

The New York City (NYC) Dept. of Health and Mental Hygiene reported a significant recent increase in rates of new HIV diagnoses among young MSM in New York City (2). Other epidemiological studies of the HIV/AIDS epidemic

The increasing rates of new HIV infections among MSM, particularly in various subpopulations (e.g. age, ethnicity, nationality, psychiatric disorder), indicate that the causes for this surge need to be identified and new intervention strategies for reduction of risk behavior and prevention must be developed.

CONCLUSION: There has been an increase in new HIV infection in MSM. Intervention and prevention models need to be appropriate to the subpopulations of MSM with the highest rates of new infection.

SEXUAL MINORITY YOUTH IN THE AGE OF CYBERSPACE

INSTITUTIONS
1. Mount Sinai Medical Center, Psychiatry, New York, United States

AUTHORS
1. Daniel Garza¹, Dr., MD, garZAD@nychhc.org

The New York City Dept. of Health and Mental Hygiene reported that new HIV diagnoses among men who sex with men (MSM) under age 30 have increased by 33% during the past six years and that the under-30 group now account for 44% of all new diagnoses among MSM in New York City. Many such connections no longer require a computer, but only a cell phone to establish a virtual friendship, or a real world intimate connection. The ease and accessibility of the Internet has facilitated and accelerated social networking for ostracized youth. Adolescents negotiating clandestine, web-based relationships may lead to crime victimization and the spread of sexually transmitted diseases, such as HIV.

WORKSHOP ON INTERNATIONAL CLINICAL, OPERATIONAL AND HEALTH SERVICES TRAINING FOR MENTAL HEALTH RESEARCHERS

INSTITUTIONS
1. Michigan State University, Epidemiology, East Lansing, United States

AUTHORS
1. James C. (Jim) Anthony¹, Professor Dr., PhD, janthony@msu.edu

This workshop, sponsored by the WPA Section on Epidemiology and Public Health, brings together leaders and participants in collaborative international research training programs. The director or a designated representative from each participating program will give a brief presentation on the training program. After presentations, the plenary workshop discussion will cover topics and problem-solving on issues of mutual interest to the program representatives and the workshop audience, as well as networking toward future research training solutions.

THE INTERNATIONAL MENTAL HEALTH AND DEVELOPMENT DISABILITIES RESEARCH TRAINING PROGRAM AT CHILDREN’S HOSPITAL BOSTON, HARVARD MEDICAL SCHOOL & ANKARA UNIVERSITY (TURKEY)

INSTITUTIONS

CLINICAL ASPECTS OF SCHIZOPHRENIA AND RELIGION: UNDERSTANDING AND MANAGING SPIRITUAL THEMES IN PSYCHOSIS

INSTITUTIONS
1. University of Geneva, Dept. of Psychiatry, Geneva, Switzerland
2. Clinic Sonnenhalde, Dept. of Psychiatry, Riehen, Switzerland
3. Universities of Lausanne and Geneva, Dept. of Theology, Lausanne, Switzerland

AUTHORS
1. Sylvia Mohr, Dr., Ph.D., sylvia.mohr@hcuge.ch
2. Samuel Pfeifer, Dr., MD, pfeifer@sonnenhalde.ch
3. Pierre-Yves Brandt, Prof. Dr., PhD
4. Philippe Huguelet, Dr, MD, philippe.huguelet@hcuge.ch

Aims and Objectives: Until recently, studies on religion and schizophrenia have mainly focused on pathology (delusions and hallucinations with religious content). The role of spirituality and religious practices as a coping mechanism is beginning to receive growing interest. Spirituality can be an important aspect in the care of psychotic patients. Educational objectives of the course are: - to provide knowledge on aspects of spirituality and religious practices in schizophrenia. - to provide criteria to differentiate between pathology and religious coping. - to use tools for the evaluation of spirituality.

Methods and Materials: Presentation of information as well as small group discussions of case vignettes, focused on the specific needs from participants clinical experiences and questions raised by the course.

The workshop is supported by the WPA-Section for Religion, Spirituality and Psychiatry.

Literature:
PHENOMENOLOGY AND PSYCHODYNAMICS OF RELIGIOUS DELUSIONS: A PERSON-CENTERED APPROACH

INSTITUTIONS
1. Clinic Sonnenhalde, Riehen, Switzerland

AUTHORS
1. Samuel Pfeifer, Dr., MD, pfeifer@sonnenhalde.ch

Aims / Objectives: About 20 percent of patients with paranoid schizophrenia and other psychotic disorders are expressing hallucinations as well as paranoid ideas and fears with religious content. This pertains to all major world religions. What is their value in understanding the person?

Method: We studied 43 patients, who suffered from religious paranoid ideas. Content and dynamics were categorized based on chart reviews. In some cases video interviews were systematically analyzed for the individual construction of meaning.

Results: Four psychodynamic functions for the individual were identified: The delusions with religious content served the following functions:

a) explanation of psychotic experiences,
b) construction of personal meaning,
c) relief from feelings of guilt and shame,
d) psychotic forms of wish fulfillment in religious terms.

We found no correlation with religious education, and the intensity of religious content did not necessarily correlate with religious values before the index episode.

Conclusions: Diagnosis of religious delusions should follow an algorithm proposed by Siddell et al (2002). However, psychiatrists have to be careful not to confuse personally meaningful (ego-syntonic) religion in delusional patients as pathological. Rather these spiritual resources could be constructively used in coping with the long term consequences of the illness (Mohr et al., 2007). Psychiatrists should be trained to be culturally sensitive regarding religious content in psychosis.

SPIRITUALITY AND RELIGIOUSNESS: A PREDICTOR FACTOR OF OUTCOME IN SCHIZOPHRENIA

INSTITUTIONS
1. University of Geneva, Psychiatry, Geneva, Switzerland

AUTHORS
1. Sylvia Madeleine Mohr, Mrs, PhD, sylvia.mohr@hcuge.ch

Religion embraces a subjective dimension (spirituality) and a collective one (religiousness). Religion is highly prevalent in psychiatric patients all around the world and is associated with psychopathology. In a previous study among 115 outpatients with chronic psychosis, religion was either a resource (for 71%, religion sustained a positive sense of self and helped to cope with the illness) or a burden (for 14%, it exacerbated suffering).

Objectives: to assess the predictive value of religious coping and the evolution of religion among those patients.

Method: Religious and clinical assessment of the cohort at 3-years.

Results: Attrition of 20%. For positive religious coping at intake, the salience of religion was correlated with fewer symptoms (PANSS, negative scale: -.17 and general scale: -.17), better social functioning (GAS, .20) and a better quality of life (WhoQol, .20) at 3-years. Religion was still predictive of outcome after controlling for gender, age, symptoms and psychosocial functioning at intake by multivariate regression models (R²: .20 to .32). Whereas, negative religious coping at intake was correlated with more positive (.59) and general (.45) symptoms at 3-years. Religion was stable for 71% patients. For 22%, the salience of religion increased (9%) or decreased (13%) drastically. For 7%, positive and negative religious coping reversed.

Conclusion: Religion is a predictive factor of clinical outcome. Religious coping is a dynamic process. It may change in salience and reverse in helpful versus harmful coping effects. Therefore, it is of relevance to assess it systematically in clinical practice for integrative care.

IN THE DARK I STRAY: PROFESSIONAL MISINTERPRETATIONS IN AUTISTIC SPECTRUM DISORDERS

INSTITUTIONS
1. Amazonic Alpha, integrative Psychiatry, Birmingham, United Kingdom

AUTHORS
1. Ruth L. Brand Flu
2. Dr, MD, amazonicalpha@aol.com

Objective:
1. Highlighting diagnostic misinterpretations and discussing pragmatic tools to enhance the diagnostic process
2. Raising awareness of pitfalls and collusive processes and discussion of integrative therapeutic options

1. I see what you can't see

Autism is an interesting but poignant condition with a wide variety of manifestations and complications. The lack of common sense and communication deficit induces recursive unpleasant interactions. This aggravates the developmental delay, which is part of the neuro-psychological condition. Treatment options are exhaustive, but there is too little trans-professional integration. Crude diagnostic criteria induce false positive and negative cases with serious repercussions to treatment.

Co-morbidity might be an aspect of the condition or can be secondary to developmental delay due to early recursive interpersonal complications. Differential psychopathology, particularly regarding personality factors and psychosis will be discussed along other syndromes such as obsessions, catatonia and attention deficit disorder.

2. Blue crackers and a whole lot of eye

There is uncertainty on the treatment outcome of autism due to the diversity of presentation and specific neuropsychological deficits. Covert developmental delay can be perceived as psychiatric symptoms. The neuropsychological tenet imposes serious pitfalls in treatment. Psycho-trauma can be obscured or over-emphasised. Abstract thinking, narrative and empathy can be enhanced by specific interventions or improve by 'scaffolding' of the person. Reciprocal acting out is a risk. Extreme behaviour can induce serious collusive reactions. Discussions of the above with case scenarios are hoped to demystify some aspects of the condition with suggestions of psychotherapeutic interventions.

THE NECESSITY OF PSYCHOPATHOLOGY NOWADAYS

INSTITUTIONS
1. Hellenic Psychiatric Association, Greece
2. Dimokritio University of Thraki, Alexandroupoli, Greece

AUTHORS
1. Nicolas Tzavaras
2. Mr., MD, tzav3jax234ya@otenet.gr
3. Chrysoula Giannoulaki
2. Mrs., MD, chr234ya@otenet.gr

Having been initiated as a main topic of collaboration between the World Health Organisation (WHO) and the World Psychiatric Association (WPA), the classification models and tools have been insufficient for the psychiatric clinical. The psychiatric patient is a bio-psychosocial entity living in a society, so the simple form of description is not adequate for our clinical description. We think that the clinical description via empathic consideration is more appropriate, as it can lead to encourage the patient's self-knowledge. The self-knowledge can be a basic tool and a criterion for the success of any psychiatric treatment. Despite its eclipse from the mainstream, the tradition of phenomenology with the demand for the integration of meanings with causes can promote the patient's recovery.

In this workshop, we will tend to emphasize that „what may appear as naked survival is always in its roots a historical phenomenon”, following Jurgen Habermas’s call for self-reflection in „Knowledge and Human Interests”(1968)
W-15
SURVIVING AGAINST ALL ODDS: LESSONS LEARNED AFTER A DECADE OF TELEPSYCHIATRY PRACTICE

INSTITUTIONS
1. University of La Laguna. School of Medicine, Psychiatry, La Laguna, Tenerife, Spain

AUTHORS
1. Carlos De Las Cuevas¹, Prof., MD, PhD, cdelascuevas@gmail.com

Telepsychiatry can be conceived as an integrated system of mental healthcare delivery that uses telecommunications and computerized information technology as an alternative to face-to-face conventional modality. Telepsychiatry connects patients and mental health professionals, permitting effective diagnosis, treatment, education, transfer of medical data and other activities related to mental health care. Telepsychiatry is a growing field with the potential to deliver high quality; much needed assistance in a variety of settings to persons in need of mental health services. After two telepsychiatry pilot projects and seven years of telepsychiatry as a routine service, that involved 265 patients, 1260 teleconsultations and more than 1300 hours of clinical practice, we have learn some lessons that could be useful for future telepsychiatric developments. The workshop has the objective to allow a common understanding of the state of the art, increase the knowledge of each other needs/priorities and to investigate on the future strategies.

W-16
GENERAL PRACTITIONERS’ PARTICIPATION IN COMPULSORY ADMISSION

INSTITUTIONS
1. University of Aarhus, Department of General Practice, Institute of Public Health, Aarhus, Denmark

AUTHORS
1. Marianne Engberg¹, Dr., PhD, marianne.engberg@alm.au.dk

Objectives To present a review of the general practitioners’ (GPs’) participation in compulsory admission in Denmark with references to conditions in other countries, mostly European, to present an ongoing study in Denmark on the subject, and to discuss the GPs’ participation in compulsory admission.

Methods Review of literature and preliminary results from an ongoing study in Denmark using both a qualitative and quantitative approach. Individual and focus group interviews were used to explore experiences among GPs and questionnaires were used to study representativity of findings.

Results Deciding authority for the detention order of compulsory admission vary between countries and can be medical or non-medical. Advantages and disadvantages of the varying procedures for the patient, the treatment, civil rights, and for the deciding authority, are not known. In Denmark physicians are the deciding authority, mostly GPs. Participation induced both unpleasant feelings, discomfort, stress, and pleasant feelings such as professional satisfaction.

Conclusions The advantages and disadvantages of varying procedures regarding deciding authority for the detention order of compulsory admission are unclear. GPs participation in compulsory admission has both positive and negative impacts relating to the treatment of patients and working environment.

**TELE-PSYCHIATRY IN FORENSIC SETTINGS IN UK**

**INSTITUTIONS**
1. Wells Road Centre, Forensic Psychiatry, Nottingham NG3 3AA, United Kingdom

**AUTHORS**
1. Younus Saleem¹

**Objective:** To outline new developments in the field of Tele-Psychiatry in Forensic Settings and discuss its opportunities and challenges.

Having developed the first Forensic Tele-psychiatry Service in UK in 2005 the presenter has undertaken numerous forensic assessments (many resulting in hospital admissions) and given court testimony. Assessments were undertaken using the already existent video-link facilities within the criminal justice system. The above experience supports the view that Tele-psychiatry saves time, cost and improves access to psychiatric services.

A Forensic Tele-psychiatry Steering Group, with a research sub-committee, based in Nottingham coordinates research projects. The session will discuss how this is relevant to Forensic Psychiatrists and address its importance to the training of new forensic psychiatrists.

**TELEPSYCHIATRY: NORM FOR THE FUTURE**

**INSTITUTIONS**
1. Southern Illinois University School of Medicine, Psychiatry, Anna, Illinois 62906, United States
2. Wells Road Centre, Forensic Psychiatry, Nottingham NG3 3AA, United Kingdom

**AUTHORS**
1. Jagannathan Srinivasaraghavan¹, Prof, M.D., jagvan@gmail.com
2. Younus Saleem², Dr., MRCPsych, Younus.Saleem@nottsphys.nhs.uk

**Objective:** The aim is to define and describe the term Telepsychiatry and its uses in United States and United Kingdom. The American Telemedicine Association defines telemedicine as „the use of medical information exchanged from one site to another via electronic communications to improve patients’ health status.” Telepsychiatry is the delivery of psychiatric services over distances, especially via interactive video conferences. Currently there is extensive use of telepsychiatry to provide consultations and recommendations in child and adolescent, forensic, emergency and community psychiatry. Juvenile and geriatric populations have received particular attention because of the limited access in rural and under-served areas. Besides clinical consultation, telepsychiatry has many more applications in programmatic and administrative consultations, distant learning, training and research.

**Method:** Descriptive with examples of use in various settings in Psychiatry addressing both benefits and barriers. Benefits include access to care as well as cost savings. Barriers include technology, reimbursement, civil commitment, medical license and privacy issues.

**Results:** Telepsychiatry applications are increasingly utilized every year. Several studies have shown efficacy in diagnosis, treatment, therapeutic alliance and reduction in psychiatric morbidity.

**Conclusions:** Clearly telepsychiatry is here to stay and can be a valuable tool for developing countries.

**References:**

Cognitive-behavior therapy (CBT) has been demonstrated to be an effective treatment for many forms of mental disorders. However, patients typically have limited access to this treatment because of a lack of trained therapists and other barriers to care. Several computer programs have been developed to assist therapists in reaching more patients. These programs can instruct patients on basic CBT principles and can help them gain CBT skills with a variety of interactive exercises. Computer tools have also been developed to help train clinicians in CBT.

This workshop provides a learning experience in computer-assisted CBT, by briefly reviewing some of the key findings from empirical research and then demonstrating two principal forms of computer tools for CBT: a multimedia computer program that has been shown to be efficacious in treatment of depression, and a computer-assisted method for training therapists. Participants will discuss methods for implementing computer-assisted CBT in clinical practice and education.

Presentation by Jesse H. Wright, M.D., Ph.D.

Computer tools are being used increasingly to assist clinicians in delivering therapy to patients with depression, anxiety, and other psychiatric disorders. This presentation outlines the major types of computer-assisted psychotherapy and then illustrates a specific application of multimedia technology for cognitive-behavior therapy (CBT) for depression. The Good Days Ahead software described in this presentation has been tested in empirical trials and found to be an effective treatment method for major depression. Participants will view and discuss this software application for psychiatric treatment. Discussion points will include: (1) What is the acceptability of computer-assisted therapy by patients? (2) What are potential advantages of computer-assisted therapy? (3) What are the limitations and barriers to implementation of computer-assisted therapy?

(4) How can computer-assisted therapy be integrated into clinical practice?

Presentation by Douglas Turkington, M.D.

A training CD-ROM (Praxis) designed to teach cognitive-behavior therapy (CBT) to clinicians is described and illustrated. Methods for implementing CBT for anxiety and depression are presented and modeled in this interactive CD-ROM. This computer tool is combined with clinical supervision to help clinicians master the core procedures of CBT. Participants in this workshop will be able to view and discuss this computer application for teaching basic therapy skills.
Cognitive-behavior therapy (CBT) methods are being used increasingly in combination with pharmacotherapy to treat a wide variety of mental disorders, including severe mental illnesses. This workshop describes an integrative theory for combining CBT with pharmacotherapy and details specific, high yield techniques that psychiatrists and other clinicians can use in brief sessions. The emphasis is on practical interventions that can be applied in standard practice. Participants will learn how to adapt key principles of behavioral activation, cognitive restructuring, exposure and response prevention, and CBT for treatment adherence for brief sessions. Video illustrations and role plays are used to demonstrate techniques. Applications of CBT in participant’s clinical practices are discussed.

Presentation by Michael Thase, M.D.
A comprehensive model for combining cognitive-behavior therapy (CBT) with pharmacotherapy is described and illustrated with examples of specific applications for treatment of depression and anxiety. High yield methods (e.g., psychoeducation, behavioral activation, thought recording, and exposure and response prevention) which can be adapted for relatively brief sessions are discussed. This presentation is based on the clinical experiences of clinicians trained in both pharmacotherapy and CBT who find these methods to be highly compatible for use in brief sessions.

Presentation by Jesse H. Wright, M.D., Ph.D.
This presentation gives detailed illustrations of methods for combining cognitive-behavior therapy (CBT) and pharmacotherapy in brief sessions. Examples include using hierarchical exposure for anxiety disorders, teaching relapse prevention methods to patients with bipolar disorder, and treating anhedonia with CBT. Computer-assisted therapy is also discussed as a method of leveraging the clinician’s time and improving the efficiency of treatment.

Presentation by Douglas Turkington, M.D.
This presentation describes how psychiatrists can effectively integrate a basic cognitive-behavioral model and linked techniques with antipsychotic medications for treatment of people with schizophrenia. The targets of such an intervention are hallucinations and delusions. Methods for using the combined approach to improve adherence with antipsychotic medication are also discussed.

DEVELOPMENTS IN THE ASSESSMENT OF CAPACITY: VIGNETTES, ALGORITHMS AND REDUCING THE LITIGATION RISK

INSTITUTIONS
1. CNWL Foundation NHS Trust, General Adult, London, United Kingdom
2. Norfolk & Waveney Mental Health Partnership Trust, Crisis Resolution Team, Norwich, United Kingdom

AUTHORS
1. M E Jan Wise¹, Dr, MSc MRCPsych, jan@wiserminds.co.uk
2. Julian Beezhold², Dr, MRCPsych, beezhold@doctors.org.uk

The aim of the workshop is to help participants improve their ability to assess capacity and be aware of relevant tools for aiding decisions regarding capacity and consent.

Audience:
The workshop is aimed at psychiatrists of all levels. Research has shown that there is room for improving the knowledge of the principles of capacity at all levels of experience from trainee to consultant practitioner.

Method:
Teaching will be a mix of interactive exercises, demonstrations, presentation, and discussions. Initially participants will view a clinical dilemma and discuss whether capacity is present. A presentation will then inform participants of legal principles.

Objectives:
To be aware of the issues involved in assessing capacity, including relevant legal tests. To improve the assessment skills of participants. To learn about resources for assessing capacity and consent.

AUTHORS
1. Victor Ja Buwalda¹, Dr., MD, imsepk@xs4all.nl
2. Julian B Beezhold², Dr., MD

How does psychiatry as a medical specialty, and how do psychiatrists as professionals, influence and lead the significant and rapidly changing developments in mental health care? This is an issue of everyday importance to all psychiatrists, whether in the multidisciplinary workplace or in professional organisations. It is widely reported that young psychiatrists feel inadequately trained and equipped for a leadership role. Yet on the other hand more experienced psychiatrists display high levels of cynicism and burn-out. The potential danger for us as individuals and as a specialty is that we enter a state of learnt helplessness. This symposium presents four very different perspectives: Woman and leadership, Leadership in international waters, Learning to lead as a resident and the FLAME project. All presenters have experience at different levels of leadership in both national and international psychiatry. All passionately believe that as psychiatrists we can take control of our own destiny. The workshop will use their presentations to provoke discussion and debate about leadership in a context of increasingly integrated multidisciplinary mental health services. The aim is that participants will leave with new awareness and new ideas for future leadership.
WOMAN AND LEADERSHIP IN PSYCHIATRY

INSTITUTIONS
1. University of Michigan, Integrated Medicine and Psychiatric Services, Ann Arbor, United States

AUTHORS
1. Michelle B. Riba¹, Dr., MD, PhD

As a past president of the American Psychiatric Association and the fifth woman APA president, it was a great honor to serve. Throughout my years on the APA Board of Trustees and as an officer, I have been very conscious of the importance of being a good role model and mentor to woman medical students, residents and junior colleagues. Gender is important in our work and roles as leaders of professional and academic organizations. As preparation for my assuming the presidency of the APA, I was fortunate to participate in the Hedwig van Ameringen Executive Leadership in Academic Medicine (ELAM) Program for Women. ELAM was a training program for women to achieve success in their academic and professional organizations. It was also an opportunity to network, bond, form relationships and alliances, and learn from successful women from many disciplines in medicine and science. In order for our profession to have excellent leaders, both females and male, it is important to develop training opportunities for those who aspire to be officers and leaders. Our national and international psychiatry organizations can explore ways to offer joint programs and training opportunities so that we have highly skilled and inspired leaders.

LEADERSHIP IN INTERNATIONAL WATERS

INSTITUTIONS
1. Free University, Psychiatry, Amsterdam, The Netherlands

AUTHORS
1. Victor Ja Buwalda¹, Dr, MD, PhD, imsep@xs4all.nl

This presentation is about the growth of an national and international leader in Psychiatry. First as an resident and later on as a Young Psychiatrist. From a third year resident and national leader he became Secretary General of the European Federation of Psychiatric Trainees (EFPT) and later on the first president of the World Association of Young Psychiatrists and Trainees.

During this process as an national and international leader her learned how to build bridges between people, how to stimulate colleagues to achieve goals in a diplomatic way and continue to have his warm personality. In this presentation he we guide us through the sometimes rough paths climbing the international mountain of a worthwhile experience.

Learning objective:
1. to learn about the challenged in leadership in national and international organizations;
2. to learn about what good leadership is in general;
3. to learn about the competencies of good leadership as a Young Psychiatrists and Trainee.

LEARNING TO LEAD: RESIDENTS IN THE AMERICAN PSYCHIATRIC ASSOCIATION

INSTITUTIONS
1. Massachusetts General Hospital, Child Psychiatry, Boston, United States

AUTHORS
1. Abigail L Donovan¹, Dr., MD

Residents are recognized as the future practitioners of medicine and receive comprehensive education in the many areas of medical practice. More recently, residents have also been recognized as future leaders in medicine, even early on in their training. As a result, professional organizations, including hospitals, academic associations and specialty societies, are now including residents in important leadership positions. What does it take to be a resident leader? The skills required are unique to the role of the young leader and will be explored fully. The presenter will discuss the challenges and rewards of being a resident leader in the context of her role as the resident member of the American Psychiatric Association Board of Trustees.

LEARNING OBJECTIVES:
- To identify the critical components of effective leadership
- To identify the particular challenges for resident leaders
- To learn approaches to address the challenges of being a resident leader

THE FUTURE LEADERS IN MENTAL HEALTH IN EUROPE (FLAME) PROGRAM

INSTITUTIONS
1. Milestone Clinic, Psychiatry, Norwich, United Kingdom

AUTHORS
1. Julian B Bezzhold¹, Dr., MD

The FLAME program is designed to directly develop participants, from within the WHO European region, over a six-year period in order to build a lasting network of future mental health leaders who will continue to work together long after graduating. Participants will be equipped with a full range of appropriate skills, in particular including skills in working constructively together with a very diverse range of fellow future leaders. The personal contacts and shared experiences enabled by the FLAME program should contribute to delivering the highest quality of future mental health services.

Mental health is a very important but often neglected issue. Promotion of mental health and prevention and care of mental health problems should be a priority for international and local organizations, governments and health professionals. Yet despite this Mental Health services suffer internationally from a relative lack of priority and funding due to a variety of causes including the stigma attached to mental health problems.

It is common cause that in order to create local and international policy and systems to promote mental health for all, to tackle stigma and discrimination and to prevent and treat mental health problems, effective leadership and collaboration is needed. The time has come, in the long road that leads to scientific, organizational or political leadership in mental health, to devote more attention to creating an integrative understanding of mental health issues and solutions.

This presentation describes the progress to date in implementing the FLAME program.

2. Alexander Nawka, Dr
3. Murat Altin, Mr, MD
4. Takahiro Kato, Mr, MD

The purpose is to provide and exchange information about postgraduate trainings from the trainee's perspective. Each presentation should briefly describe postgraduate training in presenters country and point out strengths and more importantly weaknesses of the training. Dr. Murat will provide information on training in Middle East, Dr. Tateno on training in Japan and Dr. Nawka on Czech Republic. Standardized questioners will be distributed during the workshop to all delegates of Young Psychiatrists and consequently data will be put on the web.

PSYCHIATRY TRAINING IN TURKEY

INSTITUTIONS
1. Tokat Cevdet Aykan Devlet Hastanesi Psikiyatri Klinigi, Turkey

AUTHORS
1. Murat Altin, Mr, MD

In Turkey the Psychiatric Association of Turkey (PAT) has studies about post graduate education. In our country a Psychiatric Board to specify and enhance the standards of post graduate education is formed by PAT. Another aim of this board is to improve the knowledge and clinical skills of psychiatry specialists. Also in recent years board exams had been put into practice. These board exams are thought to be compelling for the specialists to improve themselves. Unfortunately systematic psychotherapy education is inadequate during trainee education. And this is a big defect for Turkish psychiatrists. Because of this, specialists tend to take courses some of which are institutional like PAT workshops or Society of Sexual Education or some other special courses which are accredited by international associations after graduation.

The PAT publishes the books prepared by Scientific Sections in order to contribute to the professional development of its members. And these books are free for the members of association. A new project had been started. Psychopharmacology courses are arranged by branches of PAT. At these courses, young psychiatrists have the chance to meet other academicians so they can improve their knowledge about psychopharmacology.

But post graduate education is not well organized. Psychotherapy courses are located in big cities. There is along way for Turkey to develop post graduate education.
NEW RESIDENCY PROGRAM INCLUDING PSYCHIATRY TRAINING IN JAPAN

INSTITUTIONS
1. Department of Neuropsychiatry, Graduate School of Medical Sciences, Kyushu University, Japan

AUTHORS
1. Takahiro Kato¹, Mr, MD

In Japan, a new residency program has been started since 2004. Under the traditional residency program, most clinical doctors had few trainings in psychiatric care, meanwhile most psychiatrists had few trainings in general clinical practice after graduating from six-year medical course. However, the new program contains at least one month of psychiatric training during the period of two-year residency. As a result, all of new non-psychiatric doctors will have experiences of psychiatric care and all of new psychiatrists will have experiences of general clinical practice.

Suicide is a major public health problem and the number of suicide victims has exceeded 30,000 a year since 1998 in Japan. The rates of depression are extremely high in suicide victims. People with depression tend to visit non-psychiatric doctors and they tend to spend longer time to obtain appropriate mental health care in Japan. The new residency program is expected to help to establish a smoother pathway between non-psychiatric doctors and psychiatrists, which might contribute to reduce suicide victims in Japan.

In 2006, the new residents have become the first new doctors beneficia! from the new residency program. To evaluate the new residency program, the Japan Young Psychiatrists Organization (JYPO) has started a questionnaire survey, which is sent to residents, new psychiatrists and traditional psychiatrists regarding their own residency experiences and their skills or interests in fields of psychiatry, non-psychiatric medicine and so on. The author will introduce the significance of the new system with the results at this symposium.

PSYCHIATRY TRAINING PROGRAM IN THE CZECH REPUBLIC

Until 2005, the psychiatry chair organized two-day board exams—both practical and theoretical—that were standardized across the country. For the practical exam, candidates demonstrated a complete psychiatric assessment. During the theoretical exam, candidates answered three questions from a panel of four experts. For the first board exam, candidates must have 23 months of psychiatric practice, three months of practice in internal medicine and three months in surgery.

One month practice in neurology was recommended. The second board exam was required for senior posts in psychiatry. It required an additional 36 months of practice and submission of a thesis on selected topic. Since 2005 the training for specialization in general adult psychiatry includes 5 years of practice (at least 12 months at accredited departments) with rotation in various types of wards and outpatient facilities (recommended - 30 months in general psychiatry, 6 months in outpatient facilities, 5 months addictiontology, 5 months C.A.P. and 5 months of old age psychiatry). Three-month internships in internal medicine and neurology as well as participation in continuing medical education are also obligatory. Major strength of new curriculum is rotation in various types of facilities, and fact that 3 months internships in surgery is not further required. However psychotherapy reminds underestimated with only one week of intensive psychotherapy training being sufficient condition for fulfilling the current criteria. The interest for and status of social medicine, social psychiatry and social mental health approaches decreased and young professionals are seldom encouraged to take interest in public mental health.

Globalization forces are becoming increasingly evident in psychiatric education. Countries are becoming more involved in the social, political, and economic affairs of the world, which will directly affect medicine in the future. The world is growing more complex, and consequently, people expect more and more from the profession. A lot of pressures have faced psychiatric education some of which are the fast development of neurosciences and of medical technology; the rationalization of resources; and the special importance that is granted to the quality of the medical care. A large body of knowledge relevant to psychiatry currently exists and we are enlarging it at an ever-accelerating rate. Without information management systems, the quantity of relevant knowledge is far beyond human capacity to cope. This will focus professional education process on the ability to find and use information rather than on the accumulation and instant recall of facts. Training programs are being forced to operate with funding levels that, in the light of previous experience, are thought to be inadequate. There is every reason to believe that lower levels of funding will continue for some time. Lower levels of funding do not necessarily mean that programs must be of lower quality, but it does mean that it will be different. We must think creatively about the future of medical education. These main future challenges can be put in three main domains: curriculum development, tutor development and restructuring the learning environment. All these topics will be discussed through this symposium.

At the end of this workshop each one of the attendants should be able to identify: the impacts of globalization on psychiatric education and training, the current and future challenges to psychiatrists, what is required to overcome the negative impacts of globalization.

TRAINING OF PSYCHIATRISTS IN THE ERA OF GLOBALIZATION

INSTITUTIONS
1. INSTITUTE OF PSYCHIATRY AIN SHAMS UNIVERSITY, PSYCHIATRY, CAIRO, Egypt

AUTHORS
1. Mohmaed H. Ghanem, Dr., yarazek68@asuip.net

Globalization is a process in which the traditional boundaries between individuals and societies gradually and increasingly recede. This shift of human affairs from the restricted frame of the nation to the vast theater of planet Earth not only is affecting trade and finance, it is also changing the nature of mental health challenges facing people all over the world. With globalization, responsibilities of psychiatrists are going far beyond the consultation room, and the separation between domestic and international psychiatric problems is losing its usefulness. Psychiatric education was seen as transmitting large amounts of increasingly complicated knowledge to young minds. Very little attention was given to public health and prevention or to skills required to provide leadership in health teams; or to provide the optimal mixture of knowledge and skills needed for mental and social health. So, How to read the future challenges for young trainees who will practice psychiatry for 30 years. How to make our curriculum such dynamic and informative? Today more than ever before we should think teach how to manage change.
GLOBALIZATION AND IMPACT ON PSYCHIATRIC EDUCATION AND TRAINING

INSTITUTIONS
1. KING FAISAL UNIVERSITY HOSPITALS, PSYCHIATRY, AL-KHOBAR, Saudi Arabia

Globalization forces are becoming increasingly evident in medical education. The world is growing more complex, and knowledge of science is expanding rapidly. Consequently, people expect more and more from the profession. A lot of pressures have faced medical education some of which are the fast development of medical science and of medical technology; the growing importance of social factors in the development of health services; the rationalization of resources; the special importance that is granted to the quality of the psychiatric care; and the strong involvement of information technology into psychiatry. Also, psychiatry education has been accused by many things from which weak innovative trends, financing difficulties, exaggerated development of the theoretical component, a large body of knowledge relevant to medicine currently exists and we are enlarging it at an ever-accelerating rate. Without information management systems, the quantity of relevant knowledge is far beyond human capacity to cope. This will focus professional education process on the ability to find and use information rather than on the accumulation and instant recall of facts.

GOING BEYOND GLOBALIZATION IN PSYCHIATRY

INSTITUTIONS
1. INSTITUTE OF PSYCHIATRY AIN SHAMS UNIVERSITY, PSYCHIATRY, CAIRO, Egypt

AUTHORS
1. Yasser A. M. H. Elsayed, Dr., MD, yarazek68@gmail.com

Globalization is a broad concept. It refers to the increased international mobility of goods, services, money and finance, information, people and ideas. It is the most heatedly debated subject these days and is held responsible for everything from slow down in the economy to rising unemployment to terrorism. It is important therefore to objectively discuss its negative impacts on psychiatry and mental health care. With globalization, mental health care is being forced in many countries to operate with funding levels that, in the light of previous experience, are thought to be inadequate. There is every reason to believe that lower levels of funding will continue for some time. Lower levels of funding do not necessarily mean that the service must be of lower quality, but it does mean that it will be different. Planning the psychiatric staff is essential to the good functioning of services, the quality of access to psychiatric care, and the cost and quality of psychiatric care. There is a strong need for critical changes of the policies and strategies of mental health care. This lecture will discuss such changes and more.

Are you married? Doctor I don't have schizophrenia and your drugs will not change my mind? How can you answer these questions? And what does it mean for the patient, for the family and for you? And what are the consequences of your answers? Will you succeed to maintain a healthy therapeutic relationship or you will fail? Failure to respond adequately to these questions may be followed by loss of the patient, his/her family, your reputation and may be your safety. Doctor patient relationship is the main guide of a healthy management process with patients and their families.
Although this importance it was under discussed in the past. Nowadays doctor patient relationship is a very important topic in the curriculum of training and examination of all medical specialties all over developed countries. In this workshop, a lot of ethical and cultural problems related to this relationship and a lot of questions will be discussed in small groups and recommendations for immediate interventions will be generally discussed. A specially prepared semi structured problems happened before to psychiatrists in different regions of the world will be presented for discussion. While classifications, diagnoses and current drugs may be changed over time, Doctor patient relationship and clinical skills will persist and psychiatrists must have the experience and wisdom to immediately deal with such problems to keep the management process healthy and effective.

A NEW HORIZON IN PSYCHIATRY: OUTCOME ASSESSMENT, QUALITY MANAGEMENT AND TELEPSYCHIATRIE

INSTITUTIONS
1. Free University/Altrecht GGZ, Psychiatry, Amsterdam, The Netherlands
2. Psychiatric Center Little Prins, Psychiatry, Malmo, Sweden

AUTHORS
1. Victor Ja Buwalda1, Dr., MD, imsep@xs4all.nl
2. Davor Micic2, Dr., MD

This workshop is about new developments in psychiatry. These new initiatives are capable to facilitate the work of the professional in psychiatry in routine clinical practice. This workshop has two parts: part one is about outcome assessment and quality management and part two is about telepsychiatry. In between there is a short coffee break. In the first part we will talk about the outcome of a research project on different outcome measures in the Netherlands. To instruments will be compared: the Health of the Nation Outcome Scales (HoNOS) and the Outcome Questionnaires (OQ). We will show how they can be used in routine clinical practice. Secondly we will explain a quality management model, in combination with the balanced scorecard of objectives for improvement, and how it can be used by clinicians and managers to improve their performance and their patients’ outcomes (Herrmann, 2005; Santiago, 1999). We will show the advantage of such a model and how administrators can add the results of the daily work by the professionals into the system. The system will give more structure to the professional and organisation on a micro level (the doctor-patient-relationship). In the second part we will talk about the possibilities of tele-psychiatry, its advantages and how to implement this new method. We will explain through a research-project in Denmark the possibilities. At the end we will invite the attendees to participate in a worldwide research-project under supervision of the presenters.

THE USE OF THE HEALTH OF THE NATION OUTCOME SCALES (HONOS) AND THE OUTCOME QUESTIONNAIRE (OQ) AS TOOLS FOR ROUTINE CLINICAL OUTCOME MEASURES FOR PATIENTS WITH MODERATE TO SEVERE MENTAL ILLNESSES

INSTITUTIONS
1. Free University of Amsterdam/Altrecht GGZ, Psychiatry, Amsterdam, The Netherlands
2. GGZ Buitenamstel/Free University, Psychiatry, Amsterdam, The Netherlands
3. AMC, Psychiatry, Amsterdam, The Netherlands

AUTHORS
1. Victor JA Buwalda1, Dr., MD, imsep@xs4all.nl
2. Jan H. Smit2, PhD
3. Jan A Swinkels3, Dr., MD, PhD
4. Willem van Tilburg4, Dr., MD, PhD

Objective: to study the characteristics and usefulness of the Honos, and the OQ, in routine clinical practice for patients with moderate to severe mental illnesses.

Content: more transparency is needed during the treatment of mentally ill patients, not only for patients but also for professionals and managers. To enhance the quality of treatment there is need for routine outcome assessment with measures that are easy to use and that give insight into treatment response. The Honos and OQ are two of these measures.

Methods: Instruments: The Honos is a 12 item staff-rated assessment of clinical problems and social functioning. The OQ is a 45 items self-assessment of symptom distress, interpersonal relations and social role.

Procedure 500 patients in a rural clinical setting were routinely assessed with the Honos and the OQ every 6-12 weeks, for a time period of 2 years.

Results: psychometric characteristics of the Honos and OQ will be presented as their usefulness for monitoring clinical symptoms in terms of reliability, validity and the ability to show clinical significant improvement and reliable change.

Importance: To enhance quality of care we have to find outcome measures that can help the professional to evaluate treatment results in a short time frame. It also benefits the patient and manager.
THE QUALITY INFORMATION SYSTEM: A NEW SYSTEM FOR MEASURING PROGRESS IN THE DOCTOR-PATIENT RELATIONSHIP

INSTITUTIONS
1. Free University of Amsterdam/Altrecht GGZ, Psychiatry, Amsterdam, The Netherlands
2. Altrecht GGZ, Psychiatry, Utrecht, The Netherlands

AUTHORS
1. Victor Ja buwalda¹, Dr., MD, imsep@xs4all.nl
2. Prashaant Debipersad², Mr.
3. Henk van den Berg², Dr., MD

A framework used in industry, and increasingly to address gaps in the quality of healthcare is the European Foundation of Quality Management model. This approach, in combination with a balanced scorecard of objectives for improvement, can be used by clinicians and managers to improve their performance and their patients' outcomes (Hermann, 2005; Santiago, 1999; Wagner, 1999). We developed a computerized system that easily can be introduced and used in routine clinical practice. Administrators can add the results of the daily work by the professionals into the system. The system will give more structure to the professional and organisation on a micro level (the doctor-patient-relationship) and can be used for implementing measuring instruments in the organization as a whole.

The program we use is called “The Quality Information System” (KIS) and can be used on different levels (micro, meso and macro level). In this workshop we will give an example how we use the program to introduce and implement a short measurement instrument (like the Health of the Nation Outcome Scales) that can be used to evaluate the progress of the treatment of individual patients and groups in a clinical practice, hospital or healthcare system.

INTRODUCTION: WHAT TELEPSYCHIATRY IS ABOUT

INSTITUTIONS
1. Little Prins, Psychiatry, Malmo, Sweden
2. Free University of Amsterdam/Altrecht GGZ, Psychiatry, Amsterdam, The Netherlands

AUTHORS
1. Davor Mucic¹, Dr., MD
2. Victor JA Buwalda², Dr., MD

In this presentation we will highlight to possibilities of TELEPSYCHIATRY. At the end of the 20th century there was a increasing development of possibilities to use internet. Internet made the distance between countries much smaller. An example of this kind of expansion is “telepsychiatry”. Telepsychiatry is the use of videoconferencing in order to provide mental health service on distance. The patient and the therapist can see and hear each other at the same time, like via TV-transmission.

We will talk about the do’s and dont’s of telemedicine as a useful tool for regular psychiatric treatment. We think it can lower the costs an benefits psychiatry as a whole. It is an extra possibility to treat patients on a long distant, for example in a region that has a lack of psychiatrists. We go deeper into the details of the advantage and disadvantages of this new technology that facilitates treatment on a distance.
AN EXAMPLE OF A RESEARCH PROJECTS ON
TELEPSYCHIATRY AS A NEW WAY FOR THE TREATMENT OF
PSYCHIATRIC PATIENTS

INSTITUTIONS
1. Psychiatric Center Little Prins, Psychiatry, Malmo, Sweden

AUTHORS
1. Davor Mucic1, Dr., MD

Introduction: To treat refugees and migrants in a proper way is quite difficult. Limited access to clinicians with similar cultural and ethnic background decreased speed and accuracy of diagnosis and treatment (especially psychotherapeutic intervention) is one of the main reason. A possible solution for this problem is to give refugees and migrants access to ethnic specialists by using Telepsychiatry. In Denmark a transcultural expertise centre provided treatment via Telepsychiatry. The professionals involved in the Telepsychiatry project had an ethnic background what facilitated the treatment and gave possibilities for treatment without the use of translators.

Method: In 2005 to 2007 4 stations were used in the project in a period of three years. The participants were refugees and migrants with mental healthcare problems. The professionals spoke Arabic, Polish, and Kurdish and were placed in Sweden while the patients were located in Denmark. All participants answered a 10-items questionnaire after finishing the treatment in which Telepsychiatry was used.

Results: most of the participants preferred treatment in a Telepsychiatry setting rather then treatment as usual with a translator.

Conclusion: Telepsychiatry could enhance the accessibility of mental healthcare for refugees and migrant in areas were there is a shortage and need for professionals with the same cultural and ethnic background.

Ethics is derived from the Greek word “ethics” which means “Rules of conduct that govern natural disposition in human beings”. It is the body of moral principles or values governing a particular culture or group. Ethics in psychiatry is always in a state of flux adapting to changes in the specialty & its place in the world at large.

The ethical issues that are relevant to the developing or low resource countries are in contrast to the industrialized countries. The issues such as euthanasia, surrogate motherhood, organ transplantation and gene therapy, which are on the forefront in the industrialized countries, are, for the moment, irrelevant in most developing countries. Here the ethics of scarcity, cross-cultural research, as well as the activities of multinational companies, are more relevant. The majority population in these areas is illiterate and unaware of their rights and is vulnerable to all sorts of mistreatments. There is a lack of consensus on the ethical issues and well defined ethical guidelines are needed.

Lack of resources and weak infrastructure mean that researchers in developing countries are often unable to conduct their own research. As they increasingly establish partnerships with groups from developed countries, a sound ethical framework is a crucial safeguard to avoid possible exploitation of research participants in these circumstances. Initiating early discussion of the issues with national authorities as well as the local communities concerned can help researchers to overcome the difficulties of adhering to conflicting international guidance.
OUTSOURCING CLINICAL RESEARCH - IMPLICATION FOR SOUTH ASIA

INSTITUTIONS
1. C.S.M. Medical University (Earlier K.G. Medical University), Psychiatry, Lucknow, India

AUTHORS
1. Jitendra K. Trivedi

Clinical trials are moving more to the developing countries each year and this is projected to intensify. The possible reasons for this are that there is a large patient pool in developing countries and the cost of clinical research and the time for completion of a study both is almost halved if research is conducted in the developing countries. There is also availability of well trained staff and clinicians who can conduct the clinical research and are forthcoming to participate in multi-national clinical trials

Community-related factors may make risks and benefits systematically worse in developing countries and ethical parameters of appropriateness should be expanded to include these risk factors.

The research in developing countries is under scrutiny now-a-days. Human rights violation, unethical practice and huge financial gains are some of the allegations which have been labeled to researches in developing countries. Issues have been raised about the relevance of informed consent, the ethical considerations of placebo-controlled trials and admission procedures for patients involved in research.

ETHICAL PRACTICES IN AREAS WITH LIMITED RESOURCES

INSTITUTIONS
1. Fatimah Jinnah Medical College & Sir Ganga, Psychiatry, Pakistan

AUTHORS
1. Haroon Chaudhary

Ethical standards are needed to protect patients, to assure honesty, to maintain minimum standards of quality, and to prevent the wasteful and fraudulent use of health care funds. Developed and developing countries have shared responsibilities, needs, and interests that form the basis for partnership. Both are progressing towards the alleviation of poverty and the achievement of sustainable economic development rests upon a commitment to good governance, the rule of law, sound economic policies and the protection of human rights. Progress on economic front, governance, health, education is threatened by the continuing plagues of physical (HIV/AIDS, malaria, tuberculosis, cardio vascular diseases etc) and mental illnesses (depression, schizophrenia, epilepsy, drug dependence etc).

Medical ethics and medical economics are increasingly in conflict. Ethical conduct of science leads to better scientific results because the adherence to ethical research practices leads to more attention to the details of scientific research, including quantitative and statistical techniques, and to more thoughtful collaboration among investigators. Also, the credibility of science with the general public depends on the maintenance of the highest ethical standards in research.

The purpose of this presentation is to offer recommendations for clinical practice and for public policy discussions that accept the reality of physicians' participation in common forms of managed care. It also gives understanding of clinical and ethical practices which will help psychiatrists to serve patients with mental illness in their everyday clinical activities in a manner that is respectful, engenders trust, and ultimately fosters optimal clinical care.
ETHICAL ISSUES IN CLINICAL PRACTICE - SOUTH ASIAN SCENARIO

INSTITUTIONS
1. Department of Psychiatry, University of Royal Melbourne Hospital, Australia

AUTHORS
1. Bruce Singh

Clinical practice in psychiatry in South Asia is predominantly institutionally based in large old asylums. In addition such mental health care as is delivered in the community is primarily done by family practitioners or nurses. South Asia illustrates many of the ethical dilemmas associated with scarcity and the allocation of limited resources. Stigma remains a potent factor affecting the willingness of individuals and families to seek treatment. Such workforce as do exist are under considerable pressure to move from rural areas to cities and to migrate to wealthier countries. In this talk I will explore some of these issues as they affect ethical practice in South Asia.

ETHICAL ISSUES IN EAST ASIA-PATTERNS OF PSYCHOTROPIC DRUG USE

INSTITUTIONS
1. Seinan-Gakuin University, Japan

AUTHORS
1. Shinfuka Naotaka

Psychotropic drugs play a key role in modern psychiatry all over the world. Psychotropic drugs are the most important agents in the treatment of mental diseases. On the other hand, psychotropic drugs produce harmful side effects. It is true that many patients in Asia are suffering from various kinds of side effects such as extra-pyramidal signs, metabolic syndrome and damages to liver functions. Some countries are reputed with the high dose prescription and poly drug use. The actual prescription patterns of psychotropic drugs are not well studied in countries and areas in Asia. The author has collaborated with psychiatrists in China, Korea, Japan, Taiwan, Hong Kong and Singapore since 2,000 to review prescription pattern of anti-psychotics and antidepressants. The project is now known as Research of East Asia Prescription Pattern (REAP). REAP is the biggest and longest lasting multi-national collaborative research project in East Asia in the field of psychiatry covering 6 countries and involving over 20 centers and more that 200 psychiatrists.

My presentation will cover, among others,
- Overview of prescription pattern of anti-psychotics in East Asia
- Changes of prescription pattern in East Asia.
- Forces to determine the prescription patterns.
- Characteristic feature of prescription in countries in East Asia.
- Ethical issues in the use of psychotropic drugs
ETHICS AND LAW

INSTITUTIONS
1. SMS Medical College, Department of psychiatry, Jaipur, India

AUTHORS
1. Lalit Batra¹, dr_lalitbatra@hotmail.com

Law is the body of rules formally sanctioned by Parliament and the Courts so as to be defined as ‘law, administered by ‘legal forum’. Psychiatry and Psychiatrists are restrained by the rules and law of the land. In ethics, the profession is restrained by self imposed rules and regulations that do not have legal sanctity. Ethics ‘fill the gaps’ in the law, often arising because the law is ‘silent’ on many matters. Psychiatry presents a unique array of difficult ethical questions. However, a major challenge is to approach psychiatry in a way that does justice to the real ethical issues. Psychiatry entails ethical dilemmas in defining normal and abnormal, diagnosis and treatment, individual freedom, confidentiality, competency, commitment and other complex issues. Some ethical guiding principles change with time and the place of practice. Fundamentally concerned with conceptual analysis rather than the collection of empirical data, ethics may not provide direct or definite answers on every issue.

I stress that ethical concepts must be analyzed with reference to clinical practice in psychiatry as well as increasing clinical research in south-east Asian countries.

While these states face a scarcity of resources to provide the clinical care to all the psychiatric patients on one hand, on the other hand, practitioners are facing pressure to keep them abreast with the research going in developed countries. These situations while, dealt effectively with the rules of the land, but at times compromise the ethics that we are expected to follow. Thus, ethical guidelines must be framed according to the cultural-needs to support the law, to fill the gap and should be able to provide the best possible care to the patients as well as clinician both in practice as well as clinical research. Many important issues that can not adequately be governed by law such as Doctor- patient relationship, autonomy, consent, informed consent, competence and technique of treatment and methods of research must be addressed.

PHYSICIAN MENTAL HEALTH, BIOLOGICAL, PSYCHOLOGICAL AND SPIRITUAL MODEL FOR CARE

INSTITUTIONS
1. Cedars Sinai Medical center, Psychiatry and behavioral neuroscience, Los Angeles. California 90049, United States

AUTHORS
1. Syed Shujat Ali Naqvi¹, Dr., Naqvis@cshs.org
2. Monisha Vasa¹, Dr., minisha.vasa@cshs.org
3. Alicia Ruelaz¹, Dr., Alicia.ruelaz@cshs.org

Maslach eloquently described burnout as erosion of the soul. Burnout is a syndrome characterized by emotional exhaustion, decreased personal satisfaction, and a sense of depersonalization in physicians exposed to chronic stress. Personal consequences of burnout include marital difficulties, substance abuse, and the development of depression and anxiety. Physician burnout has also been associated with poor prescribing habits, and increased likelihood of physician error. Depression is prevalent in physicians as in the general population; however, physicians have an increased suicide rate compared to the general population and other professionals. As psychiatrists, we are in the unique position of understanding the biological, psychological, social, and spiritual factors that affect a physician throughout training and practice. We need to assume a leading role in decreasing stigma associated with mental health care in physicians, and encouraging physicians to receive treatment for burnout and its debilitating consequences. At the conclusion of this workshop, participants should be able to understand burnout, depression and anxiety in physicians, and ways that psychiatrists can use their training to identify and treat such syndromes in our colleagues.

The workshop will be interactive, including case discussions and experiential exercises for the participants.

**EFFECT OF MATERNAL DEPRESSION ON THE COGNITIVE AND EMOTIONAL DEVELOPMENT OF CHILDREN**

**INSTITUTIONS**
1. Cedars Sinai Medical Center, Psychiatry and Behavioral Neuroscience, Los Angeles, United States

**AUTHORS**
1. Syed Shujat Ali Naqvi¹, Dr., MD, Naqvis@cshs.org
2. Monisha Vasa¹, Dr., MD

Major depression is a common disorder, with a lifetime prevalence of around 15%. An almost universal observation is the nearly two-fold prevalence of major depressive disorder in women, perhaps as high as 25% for women. Depression has a profound negative impact on a wide range of interpersonal relationships and behaviors. Multiple studies have shown the harmful effects of maternal depression on children's cognitive development and emotional development. By the age of 20 a child with an affectively ill parent has a 40% chance of experiencing an episode of depression, and that figure rises to 60% by the age of 25. These children not only inherit the genetic predisposition for depression, but also may be exposed to adverse environmental conditions that predict depressive outcomes such as parental marital discord, higher levels of interpersonal stress, and negative parent-child relationships. Due to the fact that children are exquisitely sensitive to interpersonal contacts, and mothers constitute a major proportion of the child's social environment, the importance of understanding the impact of maternal depression on children's growth and cognitive development cannot be underestimated. At the conclusion of this session, the participant should be able to understand the impact of maternal depression on children's cognitive and emotional development.

**THE FORENSIC ASSESSMENT IN WORKPLACE HARASSMENT CLAIMS**

**INSTITUTIONS**
1. Universidad Complutense, Psychiatry, Madrid, Spain

**AUTHORS**
1. Alfredo Calcedo¹, calcedo@med.ucm.es

There is an increase in the number of claims related to workplace harassment and subsequent damage compensation specially in Europe. This type of litigation is directly related to the type of legislation that protects workers. The more protective is the legislation the bigger number of claims. Usually the alleged consequences of the harassment are psychiatric disorders, particularly mood disorders. Generally the clinician who attends the patient/ victim of the alleged workplace harassment is asked to validate not only the psychiatric diagnosis but also the causal relationship between the incidents in the workplace and the psychiatric disorders. The forensic psychiatrist is usually asked to review all the evidence that includes medical examination, legal documents, reports and videos from private investigators, etc. It is not uncommon that beside the harassment allegations other complaints arise like stress related to work overload and burnout. Other elements of organisational psychology should be taken into consideration.

In the workshop it will be reviewed the methodology for these assessments and how to systematise the evidence and present it in Court.
W-34

STRATEGIES FOR BENZODIAZEPINE DISCONTINUATION

INSTITUTIONS
1. University of British Columbia Hospital/Vancouver General Hospital, Psychopharmacology, Vancouver, Canada

AUTHORS
1. James J. Kim², Dr., PharmD, james.kim@vch.ca

Background:
The undesirable effects of chronic benzodiazepine use pose a serious challenge to the treatment of psychiatric illness, especially in persons with mental disorders and with other substance abuse history. The withdrawal symptoms can often overlap with presenting symptoms of psychiatric illnesses or interfere with therapy plan.

Aims:
1) Describe and identify withdrawal symptoms associated with long-term benzodiazepine use.
2) Familiarize with successful benzodiazepine tapering process.
3) Review pharmacological and psychological strategies of benzodiazepine discontinuation.

Methods:
An unstructured review of the relevant literature.

Results:
This workshop will review current strategies and guidelines of benzodiazepine discontinuation in patients with long-term benzodiazepine exposure. It will also address the need for psychological support and proper dosing withdrawal schedule. The use of hands-on case models will enable practice-oriented application.

Conclusions:
Preliminary evidence supports the proper discontinuation of these medications with recommended protocol.

2. Paula Barrett², Professor, M.Clin.Psych., MAPS., info@pathwayshrc.com.au

In this workshop participants will learn state of the art therapy techniques to help children, siblings and parents overcome the disabling symptoms of anxiety, depression and obsessive compulsive disorder (OCD). We will also provide specific strategies to effectively treat these disorders in both adult and childhood presentations. Live DVDs will be presented and will be discussed. Researchers and practitioners will find this workshop valuable in terms of assessment and intervention. The treatment strategies described in the workshop have been empirically tested through rigorous international controlled trials (1, 2). Many of the techniques we will describe have been disseminated country wide in Australia, Canada, Mexico, Norway, Finland, Netherlands, United Kingdom, Portugal, Germany, United States and New Zealand. Additionally, these programs have been recognised by the World Health Organization as the best practice for the prevention and treatment of childhood and adolescent anxiety and depression.

3. Hana Praskova4

Social phobia is the second common psychiatric disorder in general population. It is chronic and impairing anxiety disorder, with a low rate of natural remission, producing substantial decreases in the quality of life and numerous specific social role impairment and disabilities. Over past 15 years, behavioural, cognitive, and cognitive behavioural procedures (primarily exposure and cognitive reconstruction based treatments) were found to be effective in the treatment of social phobia. The purpose of this mini workshop is to present the main principals and techniques of a short-term group cognitive behavioural therapy for generalized form of social phobia. In our work, we combine education, cognitive reconstruction, behavioural experiments, exposure therapy, social skills training and problem solving approach. This program will demonstrate how to provide significant improvement even for those with the most severe social phobia. You will learn theoretically and practically in exercises:

1. The cognitive and behavioral models of social phobia
2. The main principles of group cognitive behavioral therapy for social phobia
3. How to use CBT techniques useful for social phobia in group:
   - cognitive reconstruction;
   - social skills training with role playing;
   - behavioral experiments and exposure (including imaginal exposure);
   - problem solving.

Supported by the research project No. 1M0002375201 from Ministry of Education, Youth and Sports, the Czech Republic.

IMAGINATIVE DEATH EXPERIENCE IN HYPOCHONDRIASIS

INSTITUTIONS
1. Prague Psychiatric Centre, Czech Republic
2. 3rd Medical faculty of Charles University, Czech Republic
3. Centre of Neuropsychiatric Studies, Czech Republic
4. Out-patients Psychiatric Clinic, Czech Republic

AUTHORS
1. Jan Prasko1,2,3
2. Hana Praskova4

Patients with health-anxiety are very often unable to describe concrete consequences of their putative somatic diseases. They block their thoughts due to anxiety attended this thoughts. The health-anxious patients try not to think about illness at all, by attempting to control their thoughts or by distraction. Our method is based on therapeutic dialogue, using Socratic questioning, and inductive methods which force patient to think beyond actual blocks. In second step, patients are asked to think out all other possibilities of newly discovered future. They are forced to imagine the worse consequences of all dread situations. Dialogue is led through one's serious illness status, with its somatic, psychological and social consequences, and the dying experience to the moment of death, which has to be described with all related emotions and details. Further, we ask patients to fantasize and constellate possible „after death experiences”. In the next session the patient brings a written conception of the redoubtable situation previously discussed. Than we work with this text as in imaginative exposure therapy. This method seems to be quite effective and not too time-consuming. Several patients with health-anxiety underwent this exposure in our therapeutical groups. All of these patients profited from this therapy, as confirmed by follow-up data.

Participants will learn:
- conceptualization of health anxiety with the patient;
- Socratic questioning with the hypochondriacal patient;
- how to apply the exposure to the imaginative death experience.

Supported by the research project No. 1M0517 from Ministry of Education, Youth and Sports, the Czech Republic.
**W-39**

**CHILD PSYCHIATRY AND LEARNING DISABILITY: DEVELOPMENTAL PSYCHOLOGY OR PSYCHOPATHOLOGY? AUTISM AS PARADIGM, IMPACT ON ASSESSMENT AND TREATMENT**

**INSTITUTIONS**
1. Amazonic Alpha, integrative psychiatry, Birmingham, United Kingdom

**AUTHORS**
1. Ruth I. Brand Flu, Dr, MD, amazonicalpha@aol.com

Developmental aspects of child psychiatry and learning disabilities are core issues which differentiate the profession from general psychiatry. Despite the availability of a multi-axial diagnostic system, there is still a tenet of transposing adult psychopathology, i.e., psychotic features into child and learning disability, which confuses the diagnostic process and treatment options. The differentiation between normal development and abnormal behaviour is even more challenging in autism due to an uneven cognitive and emotional developmental profile. Infants’ vocalisations are often encouraged in an interactive manner. Similar behaviour in a person, when tainted by muscle strength, quality of voice, particularly when distracting and risky are appraised as challenging and handled accordingly. This can induce a shift to other ‘inappropriate’ behaviour. Using autism as a paradigm these issues will be discussed in context of developmental theories and vignettes will be used to illustrate observational methods, alternative explanations of behaviour, treatment options and effect of interventions.

Learning goals are: to raise awareness of developmentally related behaviour, observational methods and how to disseminate them to allied professionals and carers, and a list with alternative explanations for ‘common inappropriate behaviour’ will be provided after the workshop. Issues such as intrusiveness, eating difficulties and different types of attention deficit will pass the review in more detail.

The method of presentation will be interactive, depending on size of the audience. Toys and tools will be used for illustration material and given out to be tried out.

3. Debashis Ray, Dr, DPM, mindhealth@gmail.com
4. Dipesh Bhagabati, Dr, MD, dbhagabati@gmail.com

Bipolar Disorder has a long history. The Homeric terms mania and melancholia or the Kraepelinan manic-depressive illness have transcended into a wide gamut of etiologic, phenomenological, nosological and therapeutic aspects. Bipolar disorder remains one of the most frequently underdiagnosed and undertreated psychiatric disorders. Its complexity and multidimensional form presents particular challenges in its treatment and there is a growing need to tailor individual treatment plans. The importance of early detection & treatment as well as striving towards sustained remission, and possibly complete recovery throws the gauntlet at identifying and managing the bipolar psychopathology in two very clinically important and clinically conspicuous sub-populations, viz., children and adolescents on one hand and bipolar disorders in women on the other. Finally, bipolar spectrum is today one the most clearly defined and widely accepted entity in the “Spectrum Disorders Club” and may have clear clinical implications.

COMBINING PSYCHIATRY AND PSYCHOANALYSIS

INSTITUTIONS
1. ASM13, Psychiatry, Paris, France
2. Hospital Esquirol, Psychiatry, Paris, France

AUTHORS
1. Catherine Liermier¹, Dr., catherine.liermier@asm13.org
2. Estelle Botvinik², Dr.

Over the past five years, we have implemented a working group, bringing together Dr. Florence Quartier, psychiatrist-psychoanalyst, and a few French psychiatric trainees with various practices and duties: child and adult psychiatric work in hospital or outpatient clinic, or private practice. In this group, we carry out with a theoretical reflection based on our clinical practice: from an interview one of us had with a patient, we then try to reconstruct the psychoanalytical approach from the inner world, taking into account transference, counter-transference, unconscious functioning in order to find useful words to say to the patient.

We try to focus above all on the person, concerned with his suffering, but we also try to highlight preserved aspects in psychic functioning. This working group became gradually an important part of our medical education. It largely consolidated us in our identity of psychiatrists-psychotherapists in our daily practice. However, it seems important to us at present time to take a stand.

The work of this group falls within the scope of a broader reflection carried out in the „WPA“ Section of Psychoanalysis in Psychiatry. We will describe in details the work of the group in order to open the discussion with participants, with a clinic case: a young woman, suffering from a severe post-natal depression, has been told by her baby’s nurse: « You must enjoy the relation-ship with your baby! »

ADVANCES IN WPA SEXUAL HEALTH EDUCATIONAL PROGRAM (SHEP)

INSTITUTIONS
1. WPA, Psychiatry and Human Sexuality Section, Caracas, Venezuela

AUTHORS
1. Ruben J. Hernandez-Serrano, Dr, rh2positivo@yahoo.com

After the presentation of the WPA book Psychiatry and Human Sexuality: An Integrative approach, Mezzich JE, Hernandez-Serrano R et al, Istambul (2006), many new changes has been occurring in the field:

- New diagnostic categories related to the six phases of the Human Cycle Response including Sexual Satisfaction
- New drugs that are in the pipeline, specially Avanafil, Dapoxetine, Testosterone patches and PT-141
- New definitions by WHO regarding Sex, Sexuality and Sexual Health.
- New ways of approaching female sexuality, specially with measurement of vaginal musculature tone and training of pelvic floor.
- Increasing of mass media communications world wide regarding Sex Education
- The inclusion of Human Sexuality in Quality of Life Evaluations
- Valorations of Human Sexual Rights (Was Valencia Declaration)
- New and controversial forms of unions between sexes
- Cognitive and Behavioral Techniques for Treatment of Sexual Disorders
- Unusual sexual behaviors that are not considered now Paraphilias Homosexualities and Homophobia.
- Late onset Hypogonadism and relationships with Sex Hormones
- The relevance of these topics will be very useful for DSM-V and ICD-11

ADVANCES IN WPA SEXUAL HEALTH EDUCATIONAL PROGRAM. SEXUAL DYSFUNCTIONS AND CHRONIC PAIN PSYCHOLOGY: AN INTEGRATIVE MODEL

INSTITUTIONS
1. Facultad de Medicina UMH, Medicina Clinica, San Juan (Alicante) Spain, Spain
2. Universidad Central de Venezuela, Facultad de Medicina, Caracas, Venezuela
3. Facultad de Medicina UMH, Psicología de la Salud, San Juan (Alicante), Spain

AUTHORS
1. Felipe Navarro-Cremades, Dr, MD, felipe.navarro@umh.es
2. Rubén Hernández-Serrano, Dr, MD
3. Jesús Rodríguez-Marín, Dr, PhD
4. Julio Bobes, Dr, MD
5. María-Teresa Bascaran, Dr, MD
6. José M de la Fuente, Dr, MD

Aims/Objectives
From the basis of the sexual current diagnostic systems CIE and DSM and the chronic pain psychosocial science toward an integrative model of diagnosis and treatment of the different types of chronic sexual pain dysfunctions, enhancing pain coping and control strategies.

Methods
To update the sexual pain disorders with definitions and theoretical changes and comorbid patterns and also the recent clinical trends arising from evidence-based knowledge and clinical consensus.

Results
The label of chronic sexual dysfunctions as complex behavioral and cognitive experiences of chronic pain lets us to remain in the broad field of the human sexuality, not only as specific instances of chronic pain syndromes.

Conclusion
Chronic sexual pain dysfunctions may be usefully completed with the recent trends and issues of the chronic pain psychology enhancing the psychosocial factors in the evaluation and clinical intervention of these sexual matters of clinical interest.

COGNITIVE-BEHAVIOR THERAPY FOR SCHIZOPHRENIA

INSTITUTIONS
1. University of Louisville, Psychiatry and Behavioral Sciences, Louisville, KY, United States
2. University of Southampton, Psychiatry, Southampton, United Kingdom
3. University of Newcastle-upon-Tyne, Royal Victoria Infirmary, Newcastle-upon-Tyne, United Kingdom

AUTHORS
1. Jesse H. Wright¹, Dr., M.D., Ph.D., jwright@iglou.com
2. David G. Kingdon², Dr., M.D., D.Kingdon@soton.ac.uk
3. Douglas Turkington³, Dr., M.D., douglas.turkington@ncl.ac.uk

Cognitive-behavior therapy (CBT) has been shown to improve outcome in patients treated with medication for schizophrenia and other severe mental illnesses. CBT methods can be used to target both positive and negative symptoms, in addition to problems with adherence to pharmacotherapy. Treatment procedures are practical and can be combined with medication in a comprehensive approach to severe mental disorders.

After briefly reviewing the empirical evidence for efficacy of CBT for psychotic illnesses, this course focuses on providing participants with pragmatic tools for using CBT for schizophrenia. Specific topics covered include: optimizing the therapeutic relationship, normalizing and educating, modifying delusions, coping with hallucinations, treating negative symptoms, and promoting treatment adherence. Role play and video illustrations are used to demonstrate key points and to help participants build clinical skills.

RECOVERY, PERSON-CENTERED CARE, AND SHARED DECISION MAKING: PRACTICAL TOOLS TO PUT IT ALL TOGETHER

INSTITUTIONS
1. California Institute for Mental Health, United States
2. AliPar Inc., United States

AUTHORS
1. Neal Adams¹, Dr., MD MPH, nadamsmd@gmail.com
2. Diane Grieder², Ms., M.Ed., alipar1832@gmail.com

Objective
This 6 hour course will mix lecture/didactic presentations with opportunities for experiential learning and practical skill development. Focus will be on helping attendees to better understand the key elements of a model service delivery system designed to promote service user engagement, shared understanding of personal recovery goals and barriers, and the development of individual service plans that are based on shared-decision making. The policy, administrative and clinical implications of this approach will be considered and specific competencies for direct service staff as well as supervisors will be presented.

Methods
Following presentation of didactic material attendees will be given problem solving interactive assignments to facilitate mastery of concepts presented in the lecture portion of the course with an emphasis on opportunities to practice skills in plan development or person-centered care plans.

Results
Specific changes in delivery system design and ways of working with service users can be made to help move beyond the rhetoric of recovery and substantially change service user’s experience of care and outcomes as measured by increased self-reliance and community integration. Developing skills in person-centered service planning is an effective strategy for making these changes. Practice models with defined competencies can be mastered.

Conclusions
Policy makers, administrators and providers must have the clinical knowledge, skills and abilities, along with the capacity to direct and manage systems change, to create a more humanistic and recovery oriented mental health services system. A focus on service planning and shared decision-making is an effective vehicle for leveraging this change can be an effective change strategy.

2. WPA Section Forensic Psychiatry, Canada
3. WPA Section Forensic Psychiatry, Germany
4. WPA Section Forensic Psychiatry, Brazil

AUTHORS
1. Alfredo Calcedo1, calcedo@med.ucm.es
2. José GV Taborda4, jose@taborda.med.br
3. Julio Arboleda2
4. Norbert Konrad3

The main educational goal of this course is helping the student to understand the differences between clinical and forensic practice. There is an important difference between the methodology and the ethical framework in both settings. Clinicians willing to get involved in forensic practice should be familiar and prepared for the adversarial procedures in the courtroom that result in aggressive cross-examinations from the attorneys involved.

Psychiatrists should be prepared to defend their opinions in an honest way avoiding falling in contradictions with other pieces of evidence and the relevant scientific literature. We have observed that there is an increase in the number of legal actions against forensic psychiatrists in different jurisdictions: regulatory bodies, civil, criminal, tort law, etc.

In the course we shall present the basics on how depositions should be made, how to structure properly a written report, what evidence should be reviewed (beside clinical data), and how to prevent malpractice lawsuits related to forensic practice.

COPING UP WITH CLINICAL CHALLENGES OF RISK ASSESSMENT

INSTITUTIONS
1. University of Western Ontario, Department of Psychiatry, London, Canada
2. Regional Mental Health Care, St. Thomas, Canada

AUTHORS
1. Amresh Kumar Shrivasatra1, Dr., MD, DPM, MRCPsych, dr.amresh2@gmail.com
2. Charles Nelson2

Introduction: Risk assessment is an important area of clinical work. All of us are constantly engaged in improving it and bridging the gaps between assessment and outcome. Suicidal ideation is common in about 4% in general population and about 20% in psychiatric population. Suicide attempt and suicidal threats are together seen in about 60-70% in acute psychiatric wards as well as in crisis services. There are tools available for risk assessment of such patients however almost always this is done based upon personal clinical judgment of the clinicians. The science of suicidology is constantly evolving with changing socio-cultural perspectives. Literature suggests three main domains for origin of suicidal ideas i.e. biological domain, psychological domain and Social-Environmental Domain. The suicidal ideas have constant interplay with risk factors present in the individual who gives rise to suicidal thoughts. The cognitive set changes and cognitive control is lost which then leads to an ‘attempt’. An adequate risk assessment is one, which incorporates all the three domains of risks in the background of suicide protectors.

Objective: The objective is to educate mental health professional in skills of risk assessment and to enhance their competency in recognising and dealing with issues of clinical challenges, complexity of risk and assessment, its measurements, need for a new & comprehensive risk assessment; documentation; risk planning & risk management

Methods: the course is based on group learning method and utilizes three main contents 1. Background literature 2. Available tools. 3. Case vintage rating. Short presentations will precede group-discussion and skill building.

DETECTION, ASSESSMENT AND TREATMENT OF VICTIMS OF INTIMATE PARTNER VIOLENCE: EXPERIENCE OF THREE YEARS OF A SPECIALISED MENTAL HEALTH UNIT

INSTITUTIONS
1. Hospital Gregorio Marañón, Psychiatry, Madrid, Spain

AUTHORS
1. Alfredo Calcedo
2. Begoña Arbulo
3. Mariano De Iceta
4. Ana Mena

Intimate partner violence (IPV) has become one of the major problems in any society regardless the level of socio-economic development. Dealing with these cases in the health services is difficult for several reasons: first the tendency that society has to make invisible the violence that takes place inside the couple, second the lack of awareness and sensibility that the majority of mental health professionals have for these problems, and third the lack of training on the treatment of these patients.

In the last decade there has been in Spain a strong sensibilisation in our society for these problems. Several law have been enacted to try help the victims in the different agencies involved (education, social services, health sector, etc). In the trend was created 3 years ago the only, to the best of our knowledge, mental health unit devoted to the treatment of victims of IPV: Programa ATIENDE.

Along the course the members of our team will explain our methodology in the detection, assessment and treatment of the cases. We shall address particular ethical and legal issues like the conflict between security and confidentiality, the duty-to-report legislation for health professionals, conflicts of interest between mothers victims of IPV and the children, etc.

WOMEN WITH BIPOLAR DISORDER: CLINICAL CHALLENGES

INSTITUTIONS
1. Toronto East General Hospital, Psychiatry, Toronto, Canada

AUTHORS
1. Ruth Baruch

Gender differences have been documented in patients suffering from bipolar disorder, with women experiencing higher rates of bipolar II, co-morbidities, rapid cycling and mixed episodes. In addition, female-specific reproductive events and hormonal fluctuations appear to impact the course of bipolar disorder in women.

The management of bipolar disorders across the female reproductive life cycle (from menarche to menopause and beyond) imposes a challenge to clinicians; common agents used may lead to menstrual irregularities, weight changes, and increased risk for Polycystic Ovarian Syndrome. During pregnancy, treatment challenges include the need to balance the putative teratogenic effect of psychotropic agents with the same well-documented adverse obstetrical outcomes and neurobehavioral consequences of an untreated psychiatric condition.

Pregnant women are exposed to heightened risk for relapse, due to treatment discontinuation, and significant worsening of symptoms during the postpartum. Unfortunately, there are no decisions that are risk free and exposure is present either to illness or to medication.

In this presentation, we will critically review the existing evidence for the prevalence and risk factors for bipolar disorders in women. Evidence-based treatment options will be discussed. Specific recommendations will take into account the efficacy and safety of various agents. Particular emphasis will be put on reproductive safety and management of bipolar disorder during pregnancy and postpartum. Lastly, we will address some of the treatment strategies for women with bipolar disorder during perimenopausal and menopausal years.

AUTHORS
1. Dusica Lecic Tosevski
2. Michel Botbol

WPA Interzonal Forum
According to the WHO data mental health problems are widely spread and the global burden of diseases is rising in Europe, especially in developing countries. In order to face the challenges and build solutions, WHO Helsinki Declaration on mental health introduced the pan-European action plan on mental health focusing on many significant issues related to mental health and mental disorders. However, development of psychiatry is different in European countries and depends on many factors involving economic development, professional resource availability, national priorities and the particular culture. This symposium will deal with the impact and challenges of the Helsinki Declaration in a dialogue between WHO regional advisor for mental health and five WPA zonal representatives of the European region.

THE IMPACT OF THE HELSINKI DECLARATION

INSTITUTIONS
1. WHO Europe, Denmark

AUTHORS
1. Matthijs Muijen

Since the endorsement of the European Declaration of Mental Health (Helsinki Declaration), there has been much policy and service development across the Region. Many countries are preoccupied with the prevention of common mental health problems that are posing major public health and economic risks. Countries are also reviewing their mental health systems, gradually shifting towards community based models of care. The process of shifting from policy to implementation is challenging, and is involving psychiatrists at every level. Positive examples and challenges will be presented.
MENTAL HEALTH ISSUES OF CONCERN IN MENTAL CARE IN THE NORDIC REGION

INSTITUTIONS
1. Centre Transcultural Psychiatry, Denmark

AUTHORS
1. Marianne Kastrup

At the WHO European Conference on Mental Health held in Helsinki 2005 a main focus was the identification of European values for mental health such as equality, fairness and solidarity. The Northern European Region supports wholly the values mentioned above, and the region is characterised with its longstanding tradition to a welfare model with emphasis on public services. In many welfare societies, the overall aim has been to have a mental health service that provides free and equal access to care irrespective of sex, age, social status or ethnic background. But the consequences of globalization increasingly colours the scene and today, we know that exposure to extreme stress have psychological consequences, and that severe social adversities may influence mental health, and that the consequences are to some extent similar independent of cultural background. This fact has vast public health consequences also in the Northern European region and deserves increased public attention today. The question is however to what extent the above thoughts and aspirations have been implemented for the vulnerable marginalized populations. In my presentation I intend to discuss the interweaving of these factors seen in the perspective of ethnic minorities, including refugees, as the prototype of a population that is facing increasing social adversities in many European countries with the inherent increased risk of developing mental problems. The paper will discuss Northern European strategies to empower marginalized, vulnerable groups and work for reintegration into society for those suffering of mental disorders.

FROM THE HELSINKI DECLARATION TO THE GREEN PAPER: THE WESTERN EUROPEAN PERSPECTIVE

INSTITUTIONS
1. WPA zonal representative, France

AUTHORS
1. Michel Botbol

For the first at this level, most of the countries of a continent participated in January 2005 in Helsinki at the ministerial conference on mental health. This very important initiative launched a strong process that led to the Green Paper on mental health elaborated by the European Union to promote institutional and political reforms on mental health along the lines of the Helsinki declaration. The Green Paper is then the first governmental application of this continental strategy. Through a public consultation was the best way to open a public debate on mental health seen as one of the most important public health topic. Most of the comments from Western European psychiatrists welcomed this innovative initiative and the stress it put on non psychiatric issues in this field. This position was certainly favoured by the imposed division of competency between the member States (in charge of the providing of health resources and thus of providing psychiatric resources), and the European Community whose competency is limited to social and economic aspects, and based on one of the possible definitions of mental health in its relation with psychiatry. The critics of the Green paper underline the risk of increasing the splitting between psychiatry and mental health broadening the gap between these two interrelated fields. To the essential motto: “No public health without mental health” another essential one is opposed: “No mental health without psychiatry and no psychiatry without mental health”.

SINCE THE WHO HELSINKI DECLARATION: FROM THE PERSPECTIVE OF SOUTHERN EUROPE

INSTITUTIONS
1. Istanbul Bilgi University, Turkey

AUTHORS
1. Levent Küey

It has been three years since the Helsinki Mental Health Declaration and Action Plan had been signed by the ministers of health of the European countries. It had actually suggested a flexible guidance for implementation in individual countries. This presentation will review the developments in this context in the Southern European countries since the January of 2005. It aims to present the achievements and the challenges in the region from a transcultural perspective.

TOWARD THE MODERN HEALTH CARE VIA HELSINKI DECLARATION

INSTITUTIONS
1. Yerevan State Medical University, Armenia

AUTHORS
1. Armen Soghoyan

A WHO European Ministerial Conference on Mental Health “Facing the Challenges, Building Solutions” was held in Helsinki in 2005 and emphasized on the action plan in 12 priority areas, which are signed for the implementation by European countries. From one hand it is normal to “face the challenges” while there is a new initiative, but from another hand it is difficult to “build solution” in countries of long-lasting transitional period from Eastern European region. It is well known that people (even without mental health problems) from above mentioned countries have trouble of realization the rights adopted via European values and the situation is worst in case of mentally ill persons. Experience indicates that from ratification to implementation there is a long way to go and we value the role of international NGOs, Institutions that could facilitate this process.
MENTAL HEALTH CARE IN CENTRAL EUROPE - CASES OF GOOD PRACTICE

INSTITUTIONS
1. Institute of Mental Health, Serbia and Montenegro

AUTHORS
1. Dusica Lecic Tosevski

Development of psychiatry has similarities and differences and depends on many factors involving economic development, professional resource availability, national priorities and the particular culture. Due to prolonged adversities health system has deteriorated and is facing specific challenges. Many of the countries of the region have faced prolonged stress and difficulties due to civil conflicts, continuous political upheaval and social transition, with increasing prevalence of mental disorders. However, a movement towards renewal of collaboration, reform of psychiatry and harmonization of mental health care policies has started in these countries. Cases of good practice (Mental health project and multicentric studies involving eight countries of the region) will be presented. These cases are important steps towards the reform of psychiatry, but also towards conflict resolution and reconciliation.

Aims: The aims of this forum as organized by the Japanese Society of Psychiatry and Neurology are to share the experiences of the recent developments and the future plans for post-graduate training in Asia. For example, the specialist qualification system was recently introduced in Japan. Methods: The Chinese Society of Psychiatry, the Indian Association of Social Psychiatry, the Japanese Society of Psychiatry and Neurology, the Korean Neuropsychiatric Association and the Taiwanese Society of Psychiatry will report what has been taken place regarding post-graduate training in each country. Results: These reports will describe what has been implemented and achieved, what issues remain as challenges and what planning is being considered by the presenting societies and associations. Conclusions: These presentations will provide significant bases of information for the societies and associations in Asia and also the World Psychiatric Association. Through this forum the societies and associations can learn from each other's endeavor and aspiration and discuss how post-graduate training programs can be improved in Asia. Such discussion will provide the World Psychiatric Association a clue for the direction to consider regarding the planning of the educational training programs in Asia and in the world.

3. Lauren Durkin², Dr, PhD, lauren@inspire.org.au
4. Ian Hickie², Professor, ianh@med.usyd.edu.au

International concern exists about the increase in rates of suicidal behaviour and depression amongst young people. Suicide ranks among the top 10 causes of death in most western countries, while the World Health Organisation predicts that depression will be the second leading cause of disease and disability by 2020. Apart from impacting on the quality of a young person’s life, depression is also a major risk factor for suicide and is associated with long term health consequences in adulthood. Reach Out! (www.reachout.com.au) is an Australian web-based mental health service for young people aged 16-25. Launched in 1998, Reach Out! was the first website in the world with the express purpose of reducing youth suicide. In developed and, increasingly developing countries, access to and use of the internet is common. If we are to impact on the mental health of young people it is essential that we look to the settings in which they spend time. Debate regarding the potential dangers of the internet and the impact it has on mental health has been fierce ranging across academic disciplines, government policy, popular press and in communities. Keeping young people safe is essential but this narrow focus fails to explore the opportunities the internet affords as a setting for mental health promotion and prevention or as an adjunct to clinical care for young people experiencing mental health difficulties. This paper will present evidence of the potential role that the internet and related technology can play in improving the mental health of young people.

THE TIME FOR IMMUNOPSYCHIATRY?

INSTITUTIONS
1. McMaster University, Psychiatry and Behavioural Neurosciences, Hamilton, Canada

AUTHORS
1. Boris Sakic1, Mr., PhD, sakic@mcmaster.ca

During the 20th century various life sciences merged into new multidisciplinary fields. Accumulating evidence from neuroimmunology, psychoneuroimmunology, and psychoneuroendocrinology provided critical amounts of knowledge to support the view that mental health is controlled by a complex neuro-immuno-endocrine network, called homeostatic metasystem. Sound experimental data and numerous clinical studies suggest that brain morphology and function are compromised during systemic autoimmunity and inflammation. Psychiatric manifestations in systemic lupus erythematosus and multiple sclerosis, as well as autoimmune/inflammatory phenomena in schizophrenia and autism spectrum disorders are examples where psychiatry meets immunology. Other conditions and experimental evidence which justify the birth of Immunopsy psychiatry as a new multidisciplinary field will be reviewed at the conference.

THE BALANCE OF CARE (“PAN METRON ARISTON”)

INSTITUTIONS
1. Hellenic Centre for Mental Health and Research, Athens, Greece

AUTHORS
1. George Christodoulou1

The Panel Discussion is organized by the Psychiatric Association for Eastern Europe and the Balkans and the WPA Section of Preventive Psychiatry.

The Psychiatric Associations of the countries of Eastern Europe have identified, in a recent survey, as their main mental health concerns two basic topics: psychiatric reform and suicide prevention.

This panel discussion will deal with the first topic. Psychiatric care in Eastern Europe is presently in a transitional period from big hospital psychiatry to other forms of care, basically Community Psychiatry. Psychiatrists and planners in Eastern Europe have the advantage of a precedent - the psychiatric reform in Western Europe and thus they can identify the advantages but also the difficulties and drawbacks of this reform. For example, they are in the advantageous position to realize that what is indicated for a certain socio-political and cultural milieu is not necessarily good for another environment. They can also realize that a necessary prerequisite for closing a psychiatric hospital is to establish alternative facilities in advance and to guarantee a continuous flow of funding.

The Psychiatric Association of Eastern Europe and the Balkans (PAEEB) is currently dealing with the problems encountered on the way to de-institutionalization and the purpose of this panel discussion is to highlight them and contribute to their understanding. Each representative of an Eastern Europe Psychiatric Association will present the major problems encountered in the process of psychiatric reform in their respective countries.

REFORM OF PSYCHIATRIC SERVICE IN RUSSIA

INSTITUTIONS
1. Independent Psychiatric Association of Russia, Moscow, Russian Federation

AUTHORS
1. Liubov N. Vinogradova, Mrs., PhD, vinograd@npar.ru
2. Yuri S. Savenko, Dr., MD, info@npar.ru

In 2005 Russia signed the European Declaration on Protection of Mental Health and joined the European Plan of Actions for protection of Mental Health. In 2007 the Federal five year Program for reforming psychiatric service was adopted. It planned to transfer the accent of mental health care to help in community, to out-patient forms of help carried out by multi-professional teams of specialists and to reduce number of beds in in-patient facilities, which is 11.4 for 100 thousand people in present Russia. The main stimulating motive of the Government was reducing expenses of society in connection with mental diseases of citizens. The meaning of reform didn’t discuss as with mental health professionals as with population. Meanwhile one of the most fundamental factors determining successfulness of the reform is a level of health care financing. In Russia it is 2.7% of the GDP in 2007, whereas according to the World Health Organization health care system can’t fulfill its functions at the expenses less than 5%. In such conditions specialized care can correspond to the European Plan only in particular big centers. It is the most important on a present stage to invest funds into versatile work on development of out-patient help in community, to fix the percentage of funds for psychiatric care, to create hostels and daily inpatient centers, to provide patients with prolonged drugs, to organize groups of self-help and mutual support, to promote wide anti-stigmatization program.

VIOLENCE IN IRAQ

INSTITUTIONS
1. Consultant psychiatrist, President of Iraqi Psychiatric Association

AUTHORS
1. M. R. Lafta

Each year, over 1.6 million people worldwide lose their lives to violence. Violence is among the leading causes of death for people aged 15–44 years worldwide, accounting for 14% of deaths among males and 7% of deaths among females. When violence is prolonged, it undermines the social and economic conditions of communities and nations. The consequences of armed conflict are especially devastating. The loss of parents, children, spouses, etc. is emotionally traumatic, and may have serious economic consequences for surviving members of the families as well.

Iraq with a history of bloody violence is not lucky through what it has subjected to occupation, invasion, destruction, killing, deportation, and elimination during the previous centuries. There are several cornerstones of violence in Iraq which need to be discussed in details.

Non-violence education is very crucial for the future of Iraq.

THE BICOMMUNAL RECONCILIATION PROCESS IN CYPRUS

AUTHORS
1. Argyris Argyriou

The reconciliation process in Cyprus between the Turkish Cypriot community and the Greek Cypriot community has been in evolution the last 20 years in systematic progressive rates. Citizens and professional groups have commenced initiatives of bilateral meetings, in times that the political conditions were not facilitating such movements. The encouragement of foreign embassies, the European Union and the United States authorities reinforced the effectiveness of this procedure.

The mental health professionals have a central role in the conflict resolution effort, in promoting the reciprocal understanding and the development of common views in the island's perspectives. The present political and socioeconomic context provides more opportunities for bicomunal collaboration and reestablishment of unanimity. In this background the maturation of social conceptions for the final solution of the Cyprus issue are being fostered. Hence the settlement seems more plausible in the near future.
CONFLICT, VIOLENCE AND MENTAL HEALTH: THE MIDDLE EAST PARADIGM

INSTITUTIONS
1. Chairman, Israel Psychiatric Association

AUTHORS
1. Avi Bleich

It seems that the continuation of the very complex conflict in the Middle East, with escalation of hostilities, the painful price in human lives and the long lasting psychological consequences, demands that mental health (MH) professionals seek and recruit all relevant resources with potential to contribute to conflict resolution, healing processes and to peace.

People living in regions of conflict and related hostilities are more exposed to traumatic events and consequently, to peri and post traumatic distress and disorders. A major contribution of MH would thus be, a collaboration among professionals, on both sides, in promoting psychosocial therapeutic models that are suitable for the specific needs of the casualties in this region, including research and training of therapists.

Another possible contribution of MH could be in influencing public opinion including leaders. This may be achieved by readiness for self examination, studying the various psychological consequences on society including expressions of distress, coping and attitudes. Such studies, when professionally validated, could raise public awareness of putative findings and insights, that may sometimes be hard to accept, but which may alter public views and attitudes and promote readiness and efforts towards peace (1,2).

In this context, a specific attention should be given to collective/national traumas. Such traumas may serve as a significant obstacle to resolution of the conflict, but can also be recruited for reconciliation processes, serving as a bridge for common aspirations for peace.

We have assessed over the past three decades the impact of war exposure on mental health in several populations using retrospective as well as prospective designs. The studied populations included targeted individuals, as well as, national samples representing the entire Lebanese population. Recurrent findings from these studies point out witnessing war events, repeated exposure to war and living in areas of terror are shared risk factors for children, adolescents and adults. Other childhood adversities and prior mental health disorders play a major role in predicting the final effect. The importance of temperament in mediating these effects is under study.

REFERENCES:
Disaster is severe disruption of ecological and psycho-social situation which greatly exceeds the coping capacity of the affected community (WHO, 1992). South Asia is a frequent victim of disasters. Poor infrastructure, adverse economic conditions and tough geographical terrain add on to the existing problems.

In October 2005, a devastating earthquake occurred in Kashmir in India. A team of mental health professionals visited the earthquake stricken area to provide mental health services five weeks after the event. The team conducted clinics at >30 sites in different villages in the area. Finding of the team have been published by R. K. Chadda and A. Malhotra (2006, 2007). The finding from the study found that adjustment disorders, depression, other stress reactions, and PTSD-like symptoms were the common mental health problems five to six weeks following an earthquake.

This presentation will describe the mental health problems encountered in those communities in the aftermath of the Kashmir earthquake.

SOUTH ASIAN TSUNAMI

AUTHORS
1. Harischandra Gambheera, Sri Lanka

To the time immemorial, the worst ever tragedy experienced by Sri Lankans had been the destruction caused by the tsunami on December 26th 2004. These tidal waves destroyed more than 1 of costal margin of Sri Lanka and significant parts of Indonesia, Malaysia, Thailand Maldives and Andaman & Nicobar Islands. During the disaster 40,000 people have lost their lives in Sri Lanka alone and approximately two hundred thousands people lost their lives in entire disaster. Thousands of children had become orphans, many thousands were injured, and further thousands are documented as missing. Destruction of thousands of houses had made millions of people homeless.

A large number of stress generation scenarios would have occurred during the disaster. Considering the speed which the escaped children and adults have lost their loved ones, the resulting stress would have been unimaginable. In addition there are enormous losses in relation to disabilities, houses, vehicles, livelihoods etc. On the other hand disruption of family structures due to loss of members could result in very complex psychosocial problems. All these factors could pose a formidable psychosocial damage. Although natural disasters and man made disasters are common in our region there is not much evidence on which the assessment of psychological damage could be based. Nevertheless expected psychological sequelae would be as high as following any other disaster perhaps would be more.

Post disaster Psychological interventions should be flexible and based on an ongoing assessment of needs. The emotional reactions should be understood based on the manifestation of various stress reactions level of individual effort invested by the people for their own construction, the pattern and degree of disability as a result of these psychological stresses etc. This is a formidable challenge to the mental health services of Sri Lanka as well as for the other countries in the South Asian region.

On the other hand there is little experience among South Asian mental health service personal in terms of managing post disaster Psychological sequelae. These deficiencies would affect children more than others. This problem is even more confounded by the underdeveloped nature of existing mental health services in this region.

PERUVIAN EARTHQUAKE

1. Peruvian Psychiatric Association, Lima, Peru

AUTHORS
1. S. Sarabia
2. J. Castro-Morales
3. H. Coloma
4. A. Castillo
5. J. Salinas
6. M. Rondon

Background:
At 06:40 p.m. local time on August 15th 2007 an earthquake measuring 7.9 degrees in the Richter scale, lasting 210 seconds struck the Department of Ica, Peru, that is located 306 km. (191 miles) south from Lima. The earthquake was followed by a 5 meter height tsunami that affected mainly Pisco and Paracas coasts and more than 20 aftershocks, which were felt by the people in the Ica region in the following week. Unlike other natural disasters, such as, a hurricane, an earthquake gives people no time to prepare. In minutes, thousands of families saw their houses collapse creating a mental health emergency. The Peruvian Psychiatric Association prepared a workshop that was held in Ica to provide participants with information on psychiatric disorders and mental health.

Aims/Objectives:
To provide participants with a positive attitude towards mental health, information on psychiatric disorders frequently seen after a natural disaster and a place for discussion of challenging issues associated with mental health within their own region.

Methods:
Pre and post tests were taken before and after the workshop to assess the extent to which the activities had an impact on the participants.

Results:
Participants increased their score after the workshop (Pre-score: 62%, Post-score: 83%)

Conclusions:
The workshop improved the participants’ knowledge on mental health problems.
The authorities of the Regional Peruvian Medical Board and other health operators at local level got engaged in a mental health network devoted to curb this emergency.

Bangladesh is basically a disaster prone country due to its geographical situation. A large part of the country is surrounded by the Bay of Bengal. Bangladesh faces natural disaster like cyclone, flood, draught and seasonal storm in different time almost every year. The country experienced most severe cyclonic storm during the year 1970 and 1991 and flood during 1988 and 1998. Recently devastating super cyclone SIDR crossed over the southern part of the country on 15 November, 2007. Fifteen districts of the southern region were badly affected. Thousands of people died, several thousand were seriously injured and infrastructures were severely damaged. World largest mangrove forest Sundarban had been badly affected.

Psycho-social morbidity among disaster affected people previously was not done. It has been reported that people of disaster affected areas develop psychiatric disaster and morbidity due to adverse life situation. Bangladesh Association of Psychiatrists (BAP) took initiative to assess the psycho-social morbidity and risk factors among the SIDR affected people. The study by BAP will be helpful in future planning regarding the management of psycho-social morbidity in disaster affected people. The psychosocial morbidity and the risk factors among the people affected by the SIDR were assessed by a group of psychiatrists after the disaster. Immediately after the SIDR disaster, the response from WPA was very prompt. WPA President was informed about the disaster and a task force was formed to face the disaster with the directive of WPA President. Five thousand U.S. Dollar was sanctioned by the WPA fund for disaster management. Echoing the WPA activities many other societies also came forward with financial assistance and verbal suggestions.

Helping the survivors with food and shelter is the first priority immediately after the disaster, followed by management of physical and psycho-social problems. Organizing local volunteers and proper training to the field level workers appears to be most helpful in the management of physical and psycho-social problems for short and long term.

May 12, 14:28, the most severe earthquake in Chinese history was happened with magnitude of 8.0 on Richter scale. Up to July 10, 2008 69197 people have been killed, 96445 hurt and 18000 lost in the earthquake that has struck Sichuan province in the southwest China. The center of the earthquake was in Wenchuan, a hilly area, about 100 km from the provincial capital Chengdu.

As early May 17, President of WPA, Prof. Mezzich asked Prof. Zhou, The Chinese Society of Psychiatry (CSP) if some supports needed. CSP wants the educational materials about psychological adding, for survivals from earthquake, especially for orphans.

After than we receive lots of emails, Prof. Prof. George Christodoulou send me many papers about this area, and sent me a CD for Crisis intervention. These papers and CD are very usefully, and we have used them in education, and in making the long term intervention plan for child and adolescents writ by CSP.

WPA have sent us 3000 $ to CSP. We have used this money to interpret a Book <Disaster Psychiatry> into Chinese, and we plan to buy the book in Chinese to send every member of CSP in the future.

1. Introducing the Case: Lee Jung−Kug
2. Viewing the Videotape of the Interview: (Interviewed by Rhee Dongshick)
3. Discussion:
4. Meet the therapist, Prof. Rhee, the founder of Tao Psychotherapy

Western psychotherapy, when it is freed from its conceptual prison, can fully resonate with Eastern Tao, and thereby can be much strengthened. After the introductory theme is addressed, the participants will view to the videotape of a patient’s interview with Prof. Rhee Dongshick, who is the founder of Tao Psychotherapy. At proper points the videotape will be interrupted for comments which are intended to highlight the patient’s subjective ‘nuclear feelings’ and the therapist’s empathic responses including ‘pointing directly at the patient’s mind.’ Then the discussants’ comments will be followed and the participants will be encouraged to freely discuss with Prof. Rhee.

Keywords: Nuclear Feeling, Tao Psychotherapy, Empathy

THE WRATH OF GOD: A FAITH−BASED SURVIVAL PARADIGM
(A PRESENTATION AND FILM ABOUT THE SURVIVORS OF THE 2005 EARTHQUAKE IN PAKISTAN)

INSTITUTIONS
1. NYU SCHOOL OF MEDICINE, PSYCHIATRY, NEW YORK, United States

AUTHORS
1. Samoon Ahmad1, Dr, MD, samoon.ahmad@med.nyu.edu

On October 8, 2005 at 8:52 am, an earthquake measuring 7.6 on the Richter scale struck Pakistan and Kashmir. More than 250,000 people perished, though the official toll remains around 80,000. The majority of the dead were children. Millions (3.5) are homeless, with no relief in sight. This oral presentation and the 17 minute movie illustrates the role of faith as a coping mechanism in the earthquake victims. The project began after my visit to the earthquake region of Pakistan and Kashmir in May, 2006, 6 months after the earthquake.

An individual's ability to cope with disaster is a function of culture, religion, faith, and belief. Common patterns of trauma have emerged among those affected by disaster, and have been the subject of numerous studies. A literature search showed that no scientific papers have been written nor any protocol developed to study this population where psychiatry is non−existent due to detachment from the modern world by virtue of its geographical inaccessibility and defiance to accept modern medicine.

Individuals in this population may cope with disaster differently since they exist as nuclear extended families with strong religious and spiritual belief systems. I interviewed and videotaped survivors utilizing the Traumatic Stress Symptom Checklist (TSSC). Despite a high prevalence of PTSD and depressive disorder, there was less incidence of suicide and more optimism due to faith and religious belief systems. The role of God was quite prevalent. Faith, religion, society and family play a large role in coping mechanisms, but do not prevent the induction of PTSD or depressive symptoms. Lack of basic necessities and resources cultivates passivity, dependency, hopelessness, resentment and ultimately the potential exploitation by extremist viewpoints.

Psychiatrists have been at the forefront of the depathologization and destigmatization of homosexuality. Many conservative religious groups have opposed this process, maintaining that homosexual behavior is immoral and mutable. They often cite statistics that have no support in the scientific community. Abomination: Homosexuality and the Ex−Gay Movement is a video produced by the Association of Gay and Lesbian Psychiatrists (AGLP), as a vehicle to understand how Lesbian, Gay, Bisexual, and Transgender (LGBT) individuals with religious backgrounds have wrestled with their religious faith. It is a documentary focusing on sexual orientation−conversion therapy (sometimes referred to as “reparative therapy”). Mainstream mental health professionals have criticized conversion therapies for the harm they cause and objected to their practitioners' overstated claims of success. Nevertheless, these “treatments” are increasingly promoted to, and practiced by, fundamentalist faith communities across the US and Europe. Abomination focuses on four individuals for whom conversion treatments have been unsuccessful: The film features the prominent psychiatrist, Robert Spitzer, MD, who explains what his controversial research on conversion therapy actually means. It presents interviews with mental health experts who have studied and written about the ex−gay movement's treatment failures, including James Scully, MD, the medical director of the American Psychiatric Association. He explains why professional mental health organizations remain concerned about the harm caused by conversion therapies. Abomination is available at AGLP's website www.aglp.org as a 31 minute DVD.

REDDUCING STIGMA AND DISCRIMINATION AGAINST OLDER PEOPLE WITH MENTAL DISORDER: THE BRAZILIAN PERSPECTIVE

INSTITUTIONS
1. Universidade Federal do Rio de Janeiro, Instituto de Psiquiatria – IPUB, Rio de Janeiro, Brazil

AUTHORS
1. Carlos Augusto de Mendonça Lima¹, Prof., MD, DSci, climasj@yahoo.com
2. Maria Cristina Reis Amendoeira², Dr., MD, cristinamendoeira@globo.com

The World Health Day 2001 motto was “Stop exclusion, dare to care”. WHO and WPA, jointly with several other NGOs published a Consensus Statement on the stigmatization and destigmatization of the elderly with mental disorders. The objectives of this meeting were to:

− promote a debate at all levels on the stigmatization
− describe the risk factors, the phenomena and the consequences of stigmatization
− stimulate, assist, promote, suggest policies, programmes and actions to combat the stigmatization.

Some terms were defined such: stigma, exclusion, discrimination, stereotypes, myths. Risk factors for stigmatization were listed such: old age, mental disorders, cultural issues and crisis situations (wars, migration of populations, socio-economic changes...). The phenomena of stigmatization was studied in its different aspects: how does stigma show itself, the amplitude of the phenomena, stigma in particular mental disorders in old age, stigma in particular contexts, who is stigmatized, who stigmatizes. The consequences were also discussed: for whom and with which consequences. Some types of strategies to combat stigma were proposed to whom, when, where, how and by whom.

In order to introduce this document in Brazil, the Rio de Janeiro State Association of Psychiatry, in collaboration with the Federal University of Rio de Janeiro has prepared a video with images of Brazilian old people in situation of stigmatization and discrimination.

ADHD THROUGH THE MOVIES

INSTITUTIONS
1. Credit Valley Hospital, Psychiatry, Toronto, Canada
2. Scaborough Hospital, Psychiatry, Scaborough, Ontario, Canada
3. University of Toronto, Canada

AUTHORS
1. Shabeer A Jeeva¹, Dr, FRCP–Canada, jeeva786@rogers.com
2. A. Turgay²,³

There is a growing awareness in educational literature that visual strategies work best for ADHD patients. The art of film–making can effectively utilized as a tool to help us navigate the emerging science of ADHD. Showing patients charts, graphs and electronic information has more appeal than auditory strategies (like an office based educational strategy). During this session I will present movies that have a clear connection to both diagnosis and treatment of ADHD:

1. Symptoms of impulsivity will be illustrated using clips from: Home Alone, Dennis the Menace and other key choices
2. Treatment strategies that illustrate the immature personality and growth will be illustrated using Mrs Doubtfire and The Lion King.

Understanding the personality profile is a major component of long term therapy, if one believes that a genetic disorder is likely to alter personality development if it affects the individual from early childhood. Therefore, the patient must deal with attachment and trust.

Fostering the therapeutic alliance with the physician can be illustrated:
1. Showing the movie Officer and a Gentleman– attacking the vulnerability of Anti– Social Personality Disorder
2. Pushing buttons with Good Will Hunting.

The participant will have a keener sense of what ails ADHD adults and the treatment strategies that will benefit them.

ONE FLEW OVER PSYCHIATRY’S NEST: THE THEORY AND PRACTICE OF PSYCHIATRY IN THE CINEMA

INSTITUTIONS
1. Riverfield Lodge clinic, South Africa

AUTHORS
1. Leverne Mountany, Dr., lmount@mweb.co.za

Psychiatry and film has grown up together. There has always been a love hate relationship between the two entities, and various stigmatizations and perceptions of the field have been a result of portrayals in film.

The aim of the workshop is to make use of film clips to evaluate the portrayal of psychiatrists and the psychiatric profession over decades. The first “movie psychiatrist” that is documented is “DR. DIPPY” in a 1906 film titled “DR. DIPPY’S SANATORIUM” and there has been a Sanatorium full of psychiatrists depicted since then!

The workshop will be looking at a variety of films eg. “Ordinary People”, “As good as it gets”, “Mr Jones”, “K– PAX”, “Girl Interrupted” and the more recent “Beautiful Mind” among others.

The workshop will also aim to create interest in using film as a successful teaching tool to lay people as well as professionals.

See you at the movies!

PSYCHOLOGICAL CHARACTERISTIC OF SPOUSES OF ALCOHOLICS

INSTITUTIONS
1. Institute for Mental Health, Belgrade, Serbia and Montenegro

AUTHORS
1. Tanja Adamovic

The concept of codependency has been advanced to explain certain psychological traits purported to be characteristic of spouses and adult children of alcoholics. To test the validity of this hypothesized syndrome, 60 female subjects living with either an alcoholic, a non-alcoholic person. Over 50% of subjects had a positive family history for alcoholism. The results revealed significantly greater levels of psychological symptomatology among the spouses of alcoholics, consistent with the hypothesized symptomatology of codependency.

CHAT SEX AND SEXUAL BEHAVIOR OF YOUNG MEN

INSTITUTIONS
1. Imam Khomeini International University, Psychology, Qazvin, Iran (Islamic Republic of)

AUTHORS
1. Abdoljavad Ahmadi, dr, PhD, jf4736@yahoo.com

Since 1995 when Goldberg first discussed “internet addiction”, various forms of this addiction have been dealt with, and under various names. Given that sexual relation outside marriage are a taboo in Iran and concerning the fundamentals of the theory of psychoanalysis on the surfacing of suppressed needs, chat sex seems to have become quite prevalent in Iran recently. The present research was carried out in 2007 in order to analyze the effect of chat sex on sexual behavior in young people. A message was posted in a chat room with all Iranian members, giving a phone number for further relations. Upon calling us, the caller was asked to take part in a phone interview within the framework of a scientific research project. 50 males, with an average age of 26.5, agreed. Of the entire participant, 80% were single, 14% married, and 6% divorced. The findings indicate that continued chat sex led to bodily contact, including sexual intercourse, 34% of the cases. 76% of the participants pointed out that chat sex intensified their sexual feelings. 58% said they felt sexually satisfied after a sex chat. 26% reported an effect on their jobs. 60% admitted they masturbated during or after sex chat. Regarding these and other findings, it appears sex chat will develop into a habit and can intensify sexual activity and masturbation.

Excessive alcohol consumption and alcohol related problems are significant public health problems worldwide. It is aimed to assess the primary health care working general practitioners’ knowledge, attitude and behavior related to the detection of risky alcohol use and brief intervention and to investigate the effect of education on these aspects.

General practitioners working in the Konak (KGSB) region (n=226) were separated into intervention and control groups with 1:2 ratio and randomized according to the health centers. Sixty two general practitioners participated in the intervention group and 73 in the control group. One hour didactic lecture + a video example of brief intervention + skills training with role playing + intervention materials (physician education booklet + patient self-help brochures + Alcohol Use Disorder Identification Test (AUDIT) + follow-up forms) were provided to intervention group. Control group had didactic lecture only. Participants answered a questionnaire related to knowledge, attitude and behavior before the implementation of the programme. The same questionnaire was applied at the end of the education sessions and at the 2.5 month follow-up.

Pre-intervention knowledge, attitude and behavior scores were similar between groups. A significant increase was observed in knowledge post-intervention scores in advantage of control group. In spite of the decrease in knowledge scores at the 2.5 month follow-up, a significant increase related to pre-intervention scores was established. No significant difference was observed in attitude and behavior scores. Some improvement in knowledge had been provided by the education programme.

NONCHEMICAL ADDICTIONS IN REHABILITATION OF CHEMICAL ADDICTS

INSTITUTIONS
1. St. Petersburg State University, Department of Psychiatry, St. Petersburg, Russian Federation

AUTHORS
1. Egorov Alexei¹, Dr, MD, PhD, draegorov@mail.ru

The spectrum of addictive disorders consists of at least two groups: chemical and nonchemical addictions. Nonchemical addictions cover all spectrum of human behavioral activity such as love, sex, work, money and shopping, religion, sport etc. It seems that each human behavioral act may be potentially addictive. In other words, normally any human being has specific polyaddictiveness when in one person several potential addictions peacefully coexist, one of them being preponderant. Potential addiction which plays the most important role in the present period of life, which does not suppress, does not force out the others we propose to call prevalent addiction.

Prevalent addiction is transient, can fall under some external action and can coexist with other potential addictions. One gets a problem when one of potential addictions begins to dominate and force out the others. In this case we talk about the dominant (fixed) addiction origin. The dominant addiction fills up the consciousness totally, forces out other potential addictions and resists external influence. Essentially dominant addiction has features close to psychopathological characteristics of idée fixe. Long-term experience shows that one addiction can easily transform into the other. It happens both in chemical and nonchemical addictions. Essentially the treatment of a socially unacceptable addiction comes to addict shift into a socially acceptable form of the addiction (stable remission). The basic idea of rehabilitation of a chemical addict should be realized in strictly individual search and following strengthening of socially acceptable nonchemical addiction. If it is impossible, the next step should be replacement therapy.

2. Esra Engin, Dr., PhD, esraengin@yahoo.co.uk
3. Sibel Gültün, Mrs.

Objective: Use of alcohol is gradually becoming more and more widespread among young individuals (1,2). This study was planned to analyze the widespread use of alcohol among university students and the contributing factors.

Method: The sample of the research consisted of 170 students who studied at Ege University in Turkey. The data were collected by two questionnaire forms. The first one was the descriptive form and second one was the information form which aimed at determining the status of alcohol use and the stories of alcohol user students.

Results: It was seen that 84.7% of students were alcohol users and 75.7% consumed alcohol when they were happy. The older the age, the more the rate of alcohol consumption becomes. The rate of alcohol consumption was meaningfully high for male students with educated parents and those who spend their spare time at cafés and bars. No meaningful relation was determined between the frequency of alcohol usage and the place inhabited for a long time, economic status, number of siblings and the alcohol use of family members.

Conclusion: The high rates portraying the widespread use of alcohol among university students have proven that it is a significant issue to be handled urgently.

Aims: The present study examined whether the deficits in prospective memory associated with recreational use of cannabis among teenagers and young adults recover following cessation of use.

Methods: An independent measures design utilising pre-existing groups of current cannabis users, previous cannabis users and non-users was employed in which an opportunity sample of 128 undergraduates studying at universities in the north east of England completed an objective video-based prospective memory task and a series of self-report questionnaires assessing failures in prospective memory, levels of anxiety and depression, use of strategies to assist remembering and recreational drug use.

Results: Analysis of covariance (ANCOVA) revealed no significant differences in the number of self-reported failures in prospective memory. Current cannabis users, however, correctly recalled significantly fewer location-action combinations during the video-based prospective memory task than both previous users and non-users with no significant differences observed between previous cannabis users and non-users. These findings were observed after controlling for age, level of anxiety and depression, use of strategies to assist remembering, and the use of other recreational drugs including alcohol, nicotine and ecstasy.

Conclusion: The findings from the objective prospective memory task in the present study suggest that current recreational cannabis use has a detrimental effect on prospective memory ability in teenagers and young adults but suggest that these observed deficits may recover following cessation of use.

AN INNOVATIVE CROSS-TRAINING PROJECT: ADDICTION COUNSELORS AND MENTAL HEALTH PROFESSIONALS’ PERSPECTIVES

INSTITUTIONS
1. Université de Sherbrooke, Sciences de la santé communautaire, Longueuil, Canada
2. Domrémy MCQ, Trois-Rivières, Canada
3. CSSS de l’énergie, Trois-Rivières, Canada

AUTHORS
1. Karine Bertrand, Dr., Ph.D., karine.bertrand@usherbrooke.ca
2. Jean-Marc Ménard, Mr., M.A., jeanmarcmenard@yahoo.ca
3. Maxime Gagnon, Dr., Ph.D.
4. Francis Picher, M., M.A.

OBJECTIVES. The aim of this study is to evaluate the implementation of an innovative cross-training method (Perreault & al., 2005) designed to improve treatment integration of dual disorders (Mueser & al., 2003). This cross-training project implies a ten weeks position rotation between 20 clinicians from a public addiction centre located in Canada and 20 clinicians working in various clinical settings (i.e. Program of Assertive Community Treatment (PACT) teams, inpatient and outpatient psychiatric clinics, primary health care). One of the specific goals of this evaluation is to improve our understanding, from addiction counselors and mental health professionals’ perspective, of: 1) clinical and organizational challenges associated with the treatment of dual disorders before and after the project; 2) the successful components of the cross-training project as well as the pitfalls.

METHODS. A focus group was conducted with each clinical team (n=20 teams) before and after their participation to the project. Thematic analyses were conducted with NVivo software.

RESULTS. Clinicians noted a lack of training about dual disorders and underlined differences in intervention philosophy among clinical settings. Cross-training is perceived as an effective way to improve collaboration between professionals as well as addiction screening. However, in order to develop new skills, clinicians said they need more supervision and suggested new collaboration modalities implying co-intervention.

CONCLUSION. Active collaboration between mental health services and addiction treatment centres need to be implemented in a long-term framework in order to be effective.

A COMPARATIVE STUDY OF ATTACHMENT STYLES OF PATIENTS WITH SUBSTANCE USE DISORDERS OF OPIOID AND NORMAL INDIVIDUALS

INSTITUTIONS
1. University of Tehran, Department of Psychology, Tehran, Iran (Islamic Republic of)

AUTHORS
1. Mohammad Ali Besharat¹, Dr., PhD, besharat@ut.ac.ir
2. Bahareh Ghafoorí¹, Mrs.
3. Reza Rostami¹, Dr., MD

Objectives: The aim of this study was to compare the attachment styles of patients with substance use disorders of opioid and normal individuals.

Methods: Two hundred and forty volunteers (120 patients, 120 normals) were included in this study. All participants were asked to complete Substance Use Disorders Questionnaire (SUDQ) and Adult Attachment Inventory (AAI). Analysis of the data involved both descriptive and inferential statistics including means, standard deviations, t-tests, Pearson's correlation coefficients, and regression analyses.

Results: The results revealed significant difference between attachment styles of the patients with substance use disorders of opioid and normal individuals. Significant negative and positive correlations were found between secure and insecure attachment styles of the patients, respectively.

Conclusion: It can be concluded that substance use disorders of opioid are influenced by attachment styles through the processes of family interactions, social control, affect regulation and self-efficacy.

Keywords: attachment theory, attachment style, substance use disorder, addiction

PRE-MORBID CHARACTERISTICS OF DRUG ADDICT PATIENTS WHO WERE HIV INFECTED

INSTITUTIONS
1. Kazakh National Medical University, Kazakhstan

AUTHORS
1. L. Bespalova

Analysis of pre-morbid characteristics of persons who were HIV-infected, and suffered from opiate narcotic drug addiction was conducted with the application of psychological methods (MMPI), psychological diagnosing of different types of attitudes towards the disease. From 11 examined patients 6 persons were diagnosed by the II B stage, 5 - by III A, 4 - by HIV encephalopathy. The length of narcotic drugs abuse was from 2 to 9 years.
During the first years of drug abuse 5 persons used a common "group" syringe. While they seemed active, they still had introvert features of character and conformity, they followed the regime of their drug addict company, entirely obeying the leader. When these persons had to resolve the issues independently, their character traits such as rigidity, inclination towards anxieties with an emphasis on social problems grew stronger. Often transitory depression developed. 6 patients' personalities were closer to extrovert type: light judgments, unstable interests, satisfaction with immediate happiness, inclination towards independent and active search for the drug. All patients had a low intellectual level.
Disclosure of HIV infection had caused two types of reactions in patients. Extroverts have "pathologically denied the disease", they were convinced in the diagnostic mistake or stated that they could have contracted the disease at the dentist. Introverts had a following reaction to the diagnosis: growing self-consciousness, anxieties together with hypochondria, very often developing depressions with panic attacks.

AUTHORS
1. Zagorka Bradic
2. Olivera Aleksic Hil
3. Dusica Lecic Tosevski

Introduction: Victims of anorexia nervosa are usually the smartest and the best adolescent girls - they are good, obedient daughters and excellent students. Their qualities are self-control and perfectionism in everything, including their diet and they perfectly deny their own being. Anorexia nervosa, with the growing prevalence in the modern times, has different evolution, from a symptom to a severe illness which requires a multidisciplinary approach to treatment.
Aim: Six short vignettes of adolescent girls with identical beginning of symptoms but with different evolution and different treatment possibilities will be presented.
Methods: Assessment of personality and family functioning in the sense of developmental phenomena and therapeutic procedures description.

Discussion and conclusion: Etiological substratum diversity of anorexia nervosa leads to a variability of clinical manifestation, with different underlying personality organization - neurotic, borderline or psychotic. The consequence of this is a different prognosis of the illness as well as the dilemma about the most adequate therapeutic approach. Driven by different prognosis of identical clinical manifestations of adolescent girls who at some point of their development suffer from have anorexia nervosa, the question is whether such a diagnose is just a symptom of different clinical identities. This question puts into focus more intensive dealing with psychodynamics of this disorder, which also implies more adequate treatment with modified psychoanalytic approaches.

STRESS, RELAPSE AND SUBSTANCE USE DISORDERS

INSTITUTIONS
1. Medical University of South Carolina, Psychiatry and Behavioral Sciences, Charleston, United States

AUTHORS
1. Kathleen T. Brady1, Dr., MD, PhD, bradyk@musc.edu

The relationship between stress, substance use disorders (SUDs) and relapse has been the subject of much recent investigation. Epidemiologic and clinical studies suggest that early life adversity, in particular childhood sexual abuse, is associated with the development of SUDs in adulthood. Individuals with SUDs commonly experience multiple life stressors, but the relationship between life stressors and relapse has not been well characterized and is likely to be complex. The rapid development of technical advances in the neurosciences has led to increased understanding of molecular biology, neurotransmitter systems and neural circuitry involved in stress response and SUDs. There is much overlap in the neurobiologic pathways involved in SUDs, psychiatric disorders and stress response. Individuals with SUD's have abnormalities in stress responding which may predict risk for relapse. In this presentation, the epidemiologic and clinical data addressing the relationship between stress and SUDs will be reviewed. Data will be presented from studies investigating the neurobiologic interface between stress and substance use disorders. Specifically, studies using human laboratory paradigms to explore stress reactivity and hypothalamic-pituitary-adrenal axis (HPA) function in alcohol and cocaine dependent individuals will be presented. These studies shed light on the mechanistic relationship between stress reactivity and relapse suggesting that abnormalities in the HPA response to stress are associated with risk for relapse. Findings also suggest that the mechanisms linking stress and substance use may be gender-specific with implications for gender differences in co-occurring psychiatric disorders and SUDs. Future research and implications for clinical interventions will be discussed.

Introduction: Literature refers that the success of obesity surgical treatment in the long-term depends less on the technical quality of the surgical procedure and more on the patient's adaptive capacity to new eating habits. Aim: To evaluate the weight evolution of patients submitted to the obesity surgery.

Method: 50 patients (12% male and 88% female), who undertook the obesity surgery, were monitored in the Morbid Obesity Surgery Ward. Variables analyzed: weight loss, excess weight loss and re-gain of weight.

Results: The age group varied between 25-66 years, with a minimum of 24 months and maximum of 61 months of post-surgery. 18% did not achieve the expected weight loss (< 35% of starting weight), 48% achieved the expected weight loss (35–45% of starting weight) and 34% lost more weight than expected (over 45% of the initial weight). Regarding the percentage of excessive weight loss: 34% did not achieve their goal (< 65% of excess weight) and 66% achieved or passed the weight loss goal (> 65% excess weight). As for the re-gain of weight, 30% maintained the minimum weight reached and 70% gained weight during the study period. Among these last, 51% gained less than 5% of the lost weight, 34% gained between 5-10% of the lost weight and only 15% gained more than 10% of the lost weight.

Conclusions: Most of the patients submitted to surgery lost weight in a satisfactory manner; however, after the weight re-gain (41%) they maintained the weight in the expected standard.

Introduction: Tobaccoism is the second greatest cause of death in developed countries, the sixth in developing countries and one of the main risk factors for heart disease.

Aim: to investigate the incidence of tobaccoism in hospitalized cardiology patients and tackle the importance to stop smoking.

Method: A protocol created by the researcher was applied on 220 patients between 2005 and 2006.

Results: Of the 220 patients, 50% were male, with an average age of 58 years, 35.4% had not completed middle school and 22.3% were illiterate. 43.2% were non-smokers, 43.2% former smokers and 10.5% smokers. Amongst the smokers, 86% mentioned they missed the cigarette during hospitalization and 82.6% presented abstinence symptoms. The most described were: craving (45%), headache (42%), “nervousness” (42%) and anxiety (37%). 82.6% mentioned that they want to stop smoking because they know cigarettes are bad for the health, 74% because they are hospitalized due to the disease and 52% would stop smoking by medical imposition. 41% mentioned the presence of smokers in the family and 40.5% live with smokers.

Conclusions: The numbers of smokers and passive smokers in this population of low social-cultural level is significant. The supply of information about tobaccoism and its harms is important, contributing to an improvement in the quality of life and greater period of living. The abstinence symptoms may negatively influence in the hospitalization, seeing that psychological factors interfere in the disease's evolution as well as treatment.

SEVERITY OF THE SYNDROME OF ABSTINENCE TO ALCOHOL: AN APPROACH IN RELATION TO THE TIME OF CONSUMPTION, LEVEL OF DEPENDENCY AND CALORIC CONTRIBUTION

INSTITUTIONS
1. Mexican Psychiatric Association, Sección Académica de Historia de la Psiquiatría, Morelia, Michoacán, Mexico

AUTHORS
1. César Campos-Farfán¹, Prof. Dr., nocup@hotmail.com

The chronic alcohol consumption is a high-priority problem of Public Health, which entails to an endless number of medical complications, early and delayed, like direct or secondary consequence of the ingestion of the same one. In many occasions, the abstinence syndrome gets to represent a complex clinical organisation and burdens. The intensity of the symptomatology and the presence of complications depend on a series of factors that aggravate it or their predisposition. The objective of the current investigation was to value the weight of some variables in the gravity of the syndrome of abstinence to alcohol. 31 selected patients went to have their treatment to the Center of Aid to Alcoholic and its Families (CAAFAF) in Mexico City, D. E., and they displayed a series of symptoms of abstinence to alcohol. The age of beginning consumption, time and the level of dependency, caloric ingestion by food and alcohol for the 24 previous hours were evaluated as well as the severity of the clinical picture. One was that the beginning of the consumption of alcoholic beverages to early ages and the long time of the same one influenced in a level of substantial dependency, whereas an important caloric contribution by alcohol altogether determined the gravity of the abstinence syndrome.

INTERACTIONS BETWEEN DRUGS OF ABUSE AND PSYCHOTROPIC MEDICATIONS

INSTITUTIONS
1. Melbourne Health, NorthWest Mental Health, Melbourne, Australia
2. Western Health, Drug & Alcohol Service, Melbourne, Australia

AUTHORS
1. Enrico Cementon, Dr, MBBS FRANZCP, Enrico.Cementon@mh.org.au

Aims/Objectives
One challenge in treating people with both mental illness and substance use problems, or so-called 'dual diagnosis', is prescribing psychotropic medication when there is a history of substance misuse. All psychotropic medications have psychoactive effects and are therefore drugs that are at risk of misuse. Furthermore, in the setting of simultaneous administration, there exists the risk of interactions between the prescribed psychotropic medications and the drugs that are not prescribed or are illegally obtained. This paper will outline some of the issues that arise in the clinical context of combined use of psychiatric drugs and substances of misuse.

Methods
There will be explanations of the pharmacological, pharmacokinetic and pharmacodynamic principles that underlie medication-drug interactions and examples of these interactions drawing on the literature. There will also be exploration of the clinical impact of these interactions, including the resulting consequences and complications.

Results
Interactions between drugs of abuse and psychotropic medications may be described as additive, synergistic and antagonistic. Drug overdose deaths and the serotonin syndrome are examples of the severe consequences of some interactions. However there is a wide range of interactions' outcomes.

Conclusions
Interactions between drugs of abuse and psychotropic medications are often unpredictable. There is a dearth of research evidence and literature in this important area. The psychiatrist must apply basic pharmacological principles in order to make informed decisions regarding choices of treatment and doses. The treatment of these patients usually requires closer monitoring and frequent review. Harm reduction strategies must address issues of drug-medication interaction.

SELF-REPORTS OF HOPELESSNESS AND URINE TESTS IN METHADONE MAINTENANCE PATIENTS

INSTITUTIONS
1. University of Western Ontario, Psychiatry, London, Canada
2. Wharncliffe Medical Clinic, Methadone Clinic, London, Canada

AUTHORS
1. Zack Cernovsky, Dr, PhD, polyglot@acmedi.com
2. Gamal Sadek, Dr, MD, gamelesadek@hotmail.com
3. Simon Chiu, Dr, MD, schiu3207@rogers.com

Aims/Objectives: Feelings of hopelessness are often hypothesized to be a precedent or potential sign of relapse in opiate addiction. We investigated whether self-reports of these feelings by patients in methadone maintenance treatment (MMT) are indeed correlated with concurrent abuse of non-prescription drugs.

Methods: 52 MMT outpatients (34 men, 18 women, mean age 33.6, SD=9.7) completed the Beck Hopelessness Scale (BHS). This 20 item questionnaire quantifies self-reports of feelings of hopelessness: the patients are asked to describe how they felt within the last 7 days. Results of urine screening tests for opiates, cocaine, oxycodone, and benzodiazepines were recorded for all 52 patients for the period of last 7 days.

Results: 67.3% of the patients scored within the normal range on BHS (scores <4), 21.2% within the category of mild hopelessness (BHS from 4 to 8), 9.6% within the moderate category (BHS from 9 to 14), and only one patient scored in the severe category (BHS>14).

With respect to urine tests, 23.1% of the patients tested positive for opiates at least once in last 7 days, 19.2% for cocaine, 7.7% for oxycodone, and 17.3% for benzodiazepines. There was no significant correlation (p<.05, 1-tailed) between the BHS scores and urine tests. Neither age nor gender were significantly correlated with results of urine tests and with BHS scores, except as follows: women more frequently tested positive for benzodiazepines (r=.25, p=.040).

Conclusion: Self-reports of mild to moderate hopelessness among MMT patients are unrelated to frequency of their concurrent abuse of opiates, cocaine, oxycodone, and benzodiazepines.

SLEEP QUALITY IN METHADONE MAINTENANCE PATIENTS AND RESULTS OF URINE SCREENING TESTS

INSTITUTIONS
1. Wharncliffe Medical Clinic, Methadone Clinic, London, Canada
2. University of Western Ontario, Psychiatry, London, Canada

AUTHORS
1. Gamal Sadek¹, Dr., MD, gamalesadek@hotmail.com
2. Simon Chiu¹, Dr., MD, schiu3207@rogers.com
3. Zack Cernovsky², Dr., PhD, polyglot@acmedi.com

Aims/Objectives: We investigated whether poor sleep quality in patients in methadone maintenance treatment (MMT) is associated with concurrent abuse of non-prescription drugs.

Methods: 30 MMT outpatients (mean age 35.5, SD=11.2) who complained about poor sleep were administered the Pittsburgh Sleep Quality Index (PSQI). Twenty other MMT outpatients (mean age 37.4, SD=10.7) with adequate sleep quality (no insomnia or restless sleep) served as controls. The methadone dosage ranged from 3 to 100 mg per day with the average at 46.6 mg, SD=24.9. Results of urine screening tests for opiates, cocaine, oxycodone, and benzodiazepines were recorded for all 50 patients.

Results: Those who complained about poor sleep were more likely to have positive urine tests for cocaine use (r=.24, p=.050) and were currently on a higher dosage of methadone than good sleepers (r=.28, p=.027) perhaps due to their lower stage of recovery from addictions. As a further step, we analyzed the relationships, within the group of poor sleepers, between the 7 standard PSQI scales and urine tests and the methadone dosage. No significant correlations were found except for those involving the methadone dosage, as follows. Higher methadone dosage was associated with urine tests more frequently positive for cocaine (r=.27, p=0.30) and for oxycodone (r=.38, p=0.03). Higher methadone dosage also correlated with lower sleep efficiency (r=.50, p=.003) defined as the ratio of time spent sleeping to time spent in bed.

Conclusion: Self-reports of poor sleep among MMT patients are more frequent among those engaged in concurrent cocaine abuse.

THE RELATIONSHIP OF QUANTITY, FREQUENCY AND THE DURATION OF CANNABIS USE TO ADDICTION

INSTITUTIONS
1. Washington University School of Medicine, Psychiatry, St. Louis, MO, United States

AUTHORS
1. Linda B. Cottler¹, Dr., PhD, MPH, cottler@epi.wustl.edu
2. Arbi Ben Abdallah¹, DES, aba@epi.wustl.edu

Investigators are using data from national studies to address pertinent questions on addiction. However, the assessments are not similar regarding quantity, frequency (Q/F) and the duration (D) of illicit drug use. The Substance Abuse Module was developed for nosological purposes; hence, it addresses full criteria for abuse and dependence for all drugs in the DSM. It also covers Q/F during the period of heaviest use and the duration of this period, along with onset and recency age of use. The DSM V Committee is interested in the age old question of how Q/F/D is associated with abuse and dependence. As a first step, we evaluated assessments, and then data collected over the years from our NIDA funded studies, specifically focused on these issues. Data from 1025 cannabis users, who are 50% male, 43% African American, 34% never married and 75% out of treatment, show that during their heaviest period of cannabis use, they used an average of 10 joints on 5 days/week for 3 years. When users were stratified by Q/F/D into quartiles, we found, as hypothesized, that heavier cannabis users (HCU) were more likely than less heavy cannabis users (LHCU) to meet individual criteria for dependence and abuse. Also, HCU vs. LHCU was associated with more moderate and severe dependence. This association can help the DSM Committee determine the usefulness of Q/F/D for predicting addiction and for understanding the clinical usefulness of collecting such information. Additionally, this data will help understand the velocity from HCU to development of dependence.

SOCIAL STRESS AND ALCOHOL BASED PSYCHOSES

INSTITUTIONS
1. Republican Drug Abuse Clinic, Chechen State University, Russian Federation

AUTHORS
1. Moussa Dalsaev
2. Roza Dalsaeva

The aim of present work is discovery of how the social stress impacts on formation of alcohol psychosis in Chechen republic during various periods of social crises.

Methods and means of research: The illness of alcoholism and alcoholic psychosis for period of 2001 up to 2007 based on statistical reports and files of patients were analyzed. As criteria of correlation the ratio between the numbers of re-identified alcohol psychosis and alcoholism were used.

Results and discussions: Due to the improvement of social situation in Chechen republic the frequency of alcohol psychoses was decreased. Alcoholism is keeps increasing. There are conclusions about the role of social crises in rising of alcohol psychoses in condition of extraordinary situations.

2. Patrice Whitehorne, Ms.
3. Monica Panton, Sis., RN
4. Ken Douglas, Dr., MPH, PhD

Aim: To describe the age of onset and pattern of substance misuse in a sample of clients admitted to the Detoxification Unit of the University Hospital of the West Indies.

Method: Data from clients admitted between January and December 2005 were disaggregated using retrospective chart extractions and analyzed using SPSS 13.0

Results: A total of 158 clients were admitted, with 144 (91.1%) males and 14 (8.9%) females. The mean age was 33.3 ± 12.85 years, range 14-77 years (p = 0.000). The majority (86, 54.4%) was from Kingston. A combination of nicotine, alcohol, cannabis and crack cocaine misuse (38, 24.1%) was the most common diagnosis, followed by a combination of nicotine, alcohol and cannabis misuse (p = 0.000).

The main drug of onset was cannabis (68, 43%) and nicotine (68, 43%), (p = 0.000), with the main drug of impact being crack cocaine (84, 53.2%), (p = 0.000). The mean age of onset for cannabis use was 16.0 ± 4.5 years, nicotine use 18.3 ± 6.8 years, alcohol use 20.6 ± 8.7 years and crack cocaine use 26.2 ± 8.3 years. The majority initiated cannabis (88, 80%), nicotine (58, 69%) and alcohol (33, 55.9%) use before the end of their adolescent years, and cocaine use (60, 73.2%) in their post adolescent years.

Conclusion: 1. There is an early age of onset in this sample of substance abusers. 2. There are implications for early prevention messages, identification and treatment of adolescent substance abusers in Jamaica.

INTRODUCTION: In recent years, it has become increasingly obvious that we now face a major problem of coping with people who have become addicted to prescribed drugs.

METHOD: This survey is on a self group of people and therefore of questionable statistical value. General shape of the survey and all of the questions are asked does not bias the answer and several drafts were made of the survey.

RESULTS:
1) It is doubtful whether TRANQUILLISERS which can provide effective relief from stress and anxiety are effective for periods beyond four months.
2) TRANQUILLISERS which are marketed as sleeping pills are no longer effective after a period of between 3 & 12 days.
3) There is no significant difference between the effects of the drugs which are marketed as TRANQUILLISERS and the effects of those which are marketed as sleeping pills.
4) Sudden withdrawal after medium to long term use may cause serious withdrawal symptoms.

CONCLUSION: This survey reveals that 3 quarters of patients are fighting on their own, without help or encouragement from their doctors. Only 1 quarter of the survey were advised by their doctors to try and cut down. Taking TRANQUILLISERS continuously for a long period (4 months) can lend to a triple problem. Firstly, the tranquilising effect may wear off. Secondly, there may be physical / mental side effects. Thirdly, there is a danger of insidious development of Dependence and subsequent difficulty in withdrawing the drug.

7. Luigi Janiri³, MD

AIMS: The concept of “addiction”, traditionally referred to the abuse of psychoactive substances, has been extended to objects, attitudes and experiences because of their potential to determine symptoms and course of diseases partially overlapping with those induced by chemical substances. According to some researchers all kinds of pathological addictions share neurobiological mechanisms, suggesting the rationale to investigate the possible presence of a greater susceptibility to develop behavioral addictions in those who have already experienced a substance related disorder.

METHODS: 120 patients with a diagnosis of Alcohol Dependence (DSM-IV) were compared with 120 healthy subjects. The two samples were assessed with psychometric tests designed to investigate the main behavioral addictions: pathological gambling, compulsive shopping, sexual, affective, internet, work and physical exercise addictions. To the pathological sample was also administered the Temperament and Character Inventory-Revised (TCI-R) in order to investigate the personality dimensions associated with addiction.

RESULTS: Results showed a major prevalence of all behavioral addictions, except for sexual and internet ones, in the clinical sample respect to the control group. Significant correlations between specific behavioral addictions and between each addiction and temperamental and character dimensions has been also founded.

CONCLUSION: This study confirmed the hypothesis that individuals who have already experienced a substance dependence, are more likely to develop other conduits of abuse or addiction, including the behavioral ones, in comorbidity. However, it seems highly plausible that in the presence of an alcohol dependence, some behaviors of addiction do not occur as clinically significant.

IMPULSIVITY AND DISSOCIATIVE EXPERIENCES IN A SAMPLE OF PATIENTS WITH ALCOHOL USE DISORDERS

INSTITUTIONS
1. Catholic University Medical School, Psychiatry and Addictive Behaviors, Rome, Italy

AUTHORS
1. Marco Di Nicola
2. Giovanni Martinotti
3. Daniela Tedeschi
4. Simona Gaglini
5. Alessia Rondoni
6. Gino Pozzi
7. Luigi Janiri

Aims. Aims of this study were to investigate impulsivity traits and dissociative experiences in a sample of patients with Alcohol Use Disorders, the significance of this association and the possible correlation with temperamental and character personality traits.

Methods. Fifty-one patients with diagnosis of Alcohol Use Disorder (DSM-IV) were consecutively recruited at the Day Hospital of Psychiatry and Addictive Behaviors of the Catholic University Medical School in Rome and assessed with the following psychometric scales: the Barratt Impulsiveness Scale, Version 11 (BIS-11), the Dissociative Experience Scale II (DES II), and the Temperament and Character Inventory - Revised (TCI-R).

Results. The mean scores obtained by the experimental group in both the BIS-11 and DES II do not differ from those estimated during the validation procedure. Pearson’s linear correlation between scores was found statistically significant (p < .05). Significant correlations with some personality dimensions have also been found.

Conclusion. It is possible that the presence of mild and transient dissociative conditions, due in part to the effects induced by the substance itself and partly to the comorbid psychopathologic framework, could lead the rise of instinctive and impulsive behaviors, not controlled by the critical capacities of the subject. Further, it is highly plausible that the tendency to impulsivity and instinctiveness can facilitate, in particular conditions of stress or vulnerability, the onset of dissociative phenomena, albeit mild and short-lived.

7. Cecilia Jorgelina De Simone, Dr., MD, ceciliadesimone@yahoo.com

Introduction: The aim of this study is to describe the principal characteristics of alcohol and tobacco abuse in patients admitted in a psychiatric service at a general hospital.

Method: We reviewed the records of 111 patients consulting between November 2006 and December 2007. They completed a self-administered questionnaire including demographic data, consulting motivation, and type of substance abused, the “Desire of drinking questionnaire” by Jimenez, Gimenez, and the Fagerstrom Test.

Results: When sending this abstract, we do have just partial results (53/111 patients). 70% of patients completed the Desire drinking questionnaire; 57%, of patients who completed the questionnaire had a high score in the desire for difficult of control factor, 43% of patients obtained scores exceeding the cut point in the positive desire reinforcement factor; 57% had a high score in the negative desire reinforcement factor; 64% of patients completed the Fagerstrom Test, 22% obtained a high score.

Conclusions: A higher number of patients had a high score in the desire for difficult of control factor and in the negative desire reinforcement factor. We expect to find more consistent results from the total results processed, which will be exhibit at the congress.

7. Maria Andrea Dörpinghaus1, Dr, MD, andreadorpinghaus@yahoo.com.ar

Introduction: The aim of this study is to describe general features of substance abuse patients admitted in a psychiatric service at a general hospital and to describe particular characteristic of craving in cocaine abusers.

Method: We reviewed the records of 111 patients consulting between November 2006 and December 2007. Patients completed a self-administered questionnaire, which included demographic data, consulting motivation, type of substance abused and the self-administered Craving questionnaire by Roger Weiss.

Results: Craving questionnaire punctuations show higher scores in question 9 which includes the possibility of being in a place where he or she used to abuse cocaine compared with craving levels at the moment of filling in the questionnaire.

Discussion: Craving questionnaire shows high scores: that's to say a high level of craving which would predict a higher possibility of consumption, when the situation of being exposed to a previous, known environment of consumption compared with current level of craving. Patients show low levels of craving at the moment of the interview and 24 hours before. This suggests that the consulting situation would act as therapeutic itself. More data in process at the moment this abstract is sent will add more conclusions and make results stronger for the presentation.

CODEINE INDUCED MANIA

INSTITUTIONS
1. Ankara Addiction Treatment, Research and Training Center, Ankara Numune Research and Training Hospital 2nd Psychiatry Clinic, Ankara, Turkey

AUTHORS
1. Gökhan Aksu1, Mr, MD, dilbaz@superonline.com
2. Baris Yilbas1, Mr, MD, dilbaz@superonline.com
3. Nesrin Dilbaz1, Assoc.Prof., MD, dilbaz@superonline.com

Codeine is methoxy derivative of morphine which is well known that drugs having codeine can be abused. We report the case of mania that appeared to be related to codeine abuse.

Case report:
Mr. M., 40 years-old married male patient who had no previous personal or family history of psychiatric disorder presented to clinic for evaluation of elevated and irritable mood and insomnia for four weeks. At the time of the interview he was found to be irritable, talkative than usual, increase energy with less need of sleep but nevertheless is no tired or fatigue, inflated sense of self importance. He had almost started to take codeine containing anti-cough medication (150-200 mg of codeine phosphate per day) 6 weeks ago. He was diagnosed as bipolar disorder manic episode due to abuse of codeine and hospitalized. We stopped codeine containing medication as soon as he hospitalized. We prescribed Olanzapine 10 mg/day and valproate 1000 mg/day at the end of first week for the reason of unremitted manic symptoms. At the end of two following his initial treatment his mood had stabilized and he begun to regain function.

Discussion: Codeine central nervous system effects include dose-related mood change, usually euphoria. Due to the abuse potential and risk of causing psychiatric disorders, the prescription of codeine containing drugs must be enlisted as controlled drugs.

Drug use is a major issue of contemporary society; efficient prevention strategies could emerge by a better understanding of people’s representation of the problem. This cross-sectional study aims to describe and compare the social representations of drug use in young Romanian students. Free associations questionnaire and a standardised one were applied, in 105 high-school, 100 Medicine and 78 Law students, all non consumers. Data were analysed by a word rank and frequency software (Evoc2000) and a factor analysis on principal components with oblique rotation. Similar social representations were found, with some differences due to age and academic profiles. In all groups they were focused on dependency. With age, both negative consequences and evaluation of drug use prevale in students’ discourse, while positive consequences like “euphoria”, “pleasure” and “fun”, associated to drug use in high-school students, are less frequent. Based on Kaisers’ eigenvalue criterion, the Principal Components Analysis resulted in a pattern matrix with three or four factors for all groups, containing elements from the main explanatory models of drug use: psychological, medical and social. Medicine students consider drug use as a pathology that needs treatment and not punishment, while Law students see this behaviour as a consequence of social context that requires a higher social control. There are no major differences in social representations by age, all having a negative evaluation basis. “Dependency” is the central core of the representations but the perceived personal risk is minimal at this age, which could explain the poor effectiveness of prevention strategies.

AMPHETAMINE RELATED SYMPTOMS: DESCRIPTIVE ANALYSIS AND REASONING

INSTITUTIONS
1. Alamal Complex for Mental Health, psychiatry, Dammam, Saudi Arabia

AUTHORS
1. Yasser Abdel Razek Mohamed Hassan Elsayed, Dr., MD, yarazek68@gmail.com
2. Ghada Refaat, Dr., MD, yarazek68@gmail.com
3. Ghada Abdel Razek, Dr., MD, yarazek68@gmail.com

This study was done to: Assess clinical features related to amphetamine withdrawal, Assess if there are changes in these features in comparison to other previous studies or not, and to study the relation between amphetamine and chronicity of psychotic symptoms

Methods: A total of 150 male amphetamine dependent inpatient were selected. Patients were subjected to the following procedures: Oral informed consent, Full psychiatric interview, Urine test for common addictive substances on admission, Symptoms checklist which have been designed by the authors to assess Clinical features associated with amphetamine, Symptom Checklist-90—Revised.

Results: Generally the present study shows that the psychotic symptoms were very common with Amphetamine dependent patients and the severity of all symptoms decreased significantly during the different phases of treatment. Delusions and hallucinations were very common during 2nd week (54% and 51% respectively) and persisted for more than 8 weeks in 24% and 10% of patients respectively.

Discussion: Some of the results are similar to previous studies as Dalmau et al 1999 and Koyama et al 1991 but still the duration of psychosis is much longer.

Conclusion: there is increased risk of psychosis with use of amphetamine and a lot of reasons may play role as starting abuse at early age , sensitization process that may lead to chronic psychosis , and adulterating substances like ephedrine that may be dangerous and can lead to permanent damage of brain serotonin nerve endings.

ECONOMIC ASPECTS OF SUBSTANCE ABUSE AND DEPENDENCE

INSTITUTIONS
1. Almal Complex for Mental Health, psychiatry, Dammam, Saudi Arabia
2. Institute of Psychiatry Ain Shams University, psychiatry, Cairo, Egypt

AUTHORS
1. Yasser A. M. H. Elsayed, Dr., MD, yarazek68@gmail.com
2. Mohamed Ali Alzahrani, Dr., PhD, yarazek68@asuip.net

WHO reported that there are more than 2 billion alcoholic in the world in addition to 1.2 billion tobacco users and more than 200 million addicts on other substances. Addiction is one of the most expensive disorders in the last years. Addiction starts at early age and is chronic in nature. In addition it is a relapsing disorder and deeply impacts the cognitive and global function of patients. Up till now still the outcome of treatment is not satisfactory. Addiction is associated with a lot of criminal problems and especially economic crimes like truancy from tax paying, washing and lightening of money. All money invested in substance is reduced from economy of the country as it does not appear in national growth domestic product. The cost of substance abuse can be classified into direct, indirect and intangible cost. The direct cost is the cost of the substance itself and treatment. The indirect cost is the cost of the years lost from productivity at work and life. The intangible cost is the cost of pain and suffering. How much the cost of a single year lost from life of our sons? How much the family pays to protect these years of life. How much the countries overall pay to protect the people from the dangerousness of substance. All these points and more will be discussed during this presentation.

On our inpatient detoxification unit, we ask patients to complete the Cumming’s Fifth Edition of the Comprehensive Quality of Life Scale (COM Q O1-A5) ,patients followed every 6 months while they are in rehabilitation program with the Scale to study how much sobriety and rehabilitation could affect their Quality of life This a self administered scale it contains both objective and subjective section, each objective and subjective axis is composed of 7 domains. these are: Material well being, Health, Productivity, Intimacy, Safety, Place in the Community and Emotional well being we use the specific information learned from the scale with motivational interviewing and intervention to help facilitate the patient going directly from our detoxification to long term rehabilitation program. To date we have information from 110 patients Thirty seven percent of these patients had psychiatric comorbidities and 55% were positive for Hepatitis C and 4% were HIV positive. we aggressively treat both psychiatric and medical comorbidities while the patients are on the unit. There were significant changes on both the subjective and the objective section of the Quality of Life Scale. After a 12-18 month rehabilitation, on the subjective scale, there was significant increase on all seven domains and on the objective scale, the results were most significant on Safety where the score changed from 13% to 65% The quality of life scale indicates that after 12 to 18 months in a rehabilitation following treatment on a medically managed detoxification unit, patients subjectively perceive the quality of their life as improved in addition to their being objective evidence of improvement.

Introduction: The psychoactive substance use is thought to be related to a more promiscuous sexual behavior; therefore, with a great risk of contamination by the HIV. This statement; however, has not been adequately investigated.

Objective: To compare sexual behavior of a group of adolescents on treatment for problems related to the use of drugs and of a control group.

Method: Forty-one adolescents on treatment at PROAD of UNIFESP, Brazil, have been evaluated in 2003, in comparison to a group of 43 adolescents from the general population.

Results: In the comparison of groups it has been observed that men under treatment presented a significant higher average number of partners and a higher mean of sexual intercourses and on the 30 days that preceded the research (p=0.05). No statistic difference was found for the frequency of condom use in the 6-month period preceding data collection. The same absence of significance was observed for sexual intercourses under the effect of psychoactive substances. Finally, 83.9% of interviewed men at PROAD and 94.7% of the general population declared they consider themselves out of risk for getting infected by HIV (p>0.05). Between the women groups these values were 70.0% and 100.0%, respectively (p=0.03).

Conclusion: Drug use is related to increased risk for HIV and STD and distinct types of risky behavior could be identified. Low self-risk perception reinforces the need of specific targeted strategies directed towards these adolescents.

PSYCHIATRY COMORBIDITY RELATED TO ALCOHOL USE AMONG ADOLESCENTS

INSTITUTIONS
1. Federal University of São Paulo, Department of Psychiatry, São Paulo, Brazil

AUTHORS
1. Thiago M Fidalgo¹, Mr., marquesfidalgo@yahoo.com.br
2. Evelyn D da Silveira¹, Mrs.
3. Dartiu X Silveira¹, Dr., PhD, dartiu@psiquiatria.epm.br

Introduction: Alcohol use is apparently related to a higher prevalence of psychiatry comorbidity, although scientific studies focusing the problem among adolescents are still lacking.

Objective: To evaluate the performance of adolescents with different patterns of alcohol use on screening instruments for psychiatry disorders.

Method: Forty-one adolescents seeking assistance for alcohol-related problems at PROAD of UNIFESP, Brazil, were compared to a non-clinical sample of 43 adolescents. These 84 users were divided in three sub-groups according to pattern of alcohol intake: non-users; mild users and heavy users. Groups were compared by means of ANOVA.

Results: The first part of SRQ aims to evaluate the presence of mental disorders. Heavy users presented significantly higher scores than the other groups (p<0.05) and, taking 7/8 as cut-off, 50.0% of them had higher risk of presenting a psychiatry diagnosis. The second part of the same instrument focuses on psychotic symptoms. Also in this case heavy users showed a higher average score (p<0.05). The same was observed for the scores on CES-D, a depression scale. Using 15/16 as cut-off, 76.9% of daily users of alcohol scored positively for depressive symptoms. In the Beck Anxiety Inventory the same was observed and 50.0% of those adolescents who drink daily could be considered at a higher risk of presenting anxiety disorders (cut-off 15/16).

Conclusion: We detected higher frequencies of mental disorders, psychotic, depressive, and anxious symptoms among adolescents who were heavy alcohol users. This data reinforces the importance of detailed diagnostic investigation among patients with substance use disorders.

Introduction: Drug use is apparently related to higher prevalence of psychiatry comorbidity, although scientific studies focusing the problem among adolescents are still lacking.

Objective: To evaluate the performance of adolescents with different patterns of alcohol use on screening instruments for psychiatry disorders.

Method: Forty-one adolescents seeking assistance for alcohol-related problems at PROAD of UNIFESP, Brazil, were compared to a non-clinical sample of 43 adolescents.

Results: The first part of self-report Questionnaire aims to evaluate the presence of mental disorders and adolescents from PROAD presented significantly higher scores than the control group (p<0.001). Taking 7/8 as cut-off, 38.5% of them had higher risk of presenting a psychiatry diagnosis. The second part of the same instrument focuses on psychotic symptoms. Also in this case the clinical population showed a higher average score (p<0.001). The same was observed for the scores on the Center for Epidemiologic Studies - Depression scale. Using 15/16 as cut-off, 74.2% of drug users scored positively for depressive symptoms. In the Beck Anxiety Inventory the same was observed and 37.8% of those adolescents under treatment could be considered at a higher risk of presenting anxiety disorders (cut-off 15/16).

Conclusion: We detected higher frequencies of mental disorders, psychotic, depressive, and anxious symptoms among adolescents who were under treatment for drug abuse. This data reinforces the importance of detailed diagnostic investigation among patients with substance use disorders.

AUTHORS
1. Thiago M Fidalgo, Mr., marquesfidalgo@yahoo.com.br
2. Evelyn D da Silveira, Mrs.
3. Dartiu X da Silveira, Dr., PhD, dartiu@psiquiatria.epm.br

Background: The Drug Use Screening Inventory (DUSI) is a questionnaire devised to identify use of alcohol and other drugs among adolescents. The psychometric properties of the instrument when used among clinical and non-clinical populations of teenagers have not yet been fully understood. The objective of the present study is to evaluate the performance of the DUSI Brazilian version in two distinct groups of adolescents.

Method: This was a cross-sectional study, developed at the Addiction Unit of the Psychiatric Department at the Federal University of São Paulo, Brazil (PROAD). Forty-one adolescent outpatients receiving treatment for problems related to drug misuse at PROAD were compared with a group of 43 adolescents from the general population. DUSI scores of both groups were compared through Student test.

Results: The mean DUSI score among the adolescents from the clinical group was 6.68 ± 3.8 whereas in the comparison group the average DUSI score was 1.88 ± 2.5 (t=6.8; p<0.001). The instrument achieved its best performance when a cut-off of 2/3 points was used, corresponding to 85% of the dependents and 70% of the non-cases being correctly identified (sensitivity = 0.85; specificity = 0.70, respectively).

Conclusions: The study of the psychometric properties of the DUSI revealed that the instrument was effective in terms of discriminating drug use among adolescents.

Acknowledgments: This research could be realized with the support of CNPq (National Council of Scientific and Technological Development).

AUTHORS
1. Thiago M Fidalgo¹, Dr., marquesfidalgo@yahoo.com.br
2. Dartiu X da Silveira¹, Dr., PhD, dartiu@psiquiatria.epm.br

Introduction: According to previous research, physicians present higher prevalence of substance use disorders when compared to general population. In our country, nevertheless, scientific studies focusing the problem are still lacking.

Objective: To evaluate the opinions and attitudes about substance use among clinical physicians.

Method: A hundred physicians of clinical areas were selected in a public hospital of São Paulo. All of them were asked to answer a questionnaire with some questions about drug use. 83% completed the research protocol properly.

Results: 60.2% of the interviewed clinicians think that physicians are more likely to develop substance use disorders than general population. 67.5% of them stated they knew a colleague presenting a substance use problem and in that in 41.0% of the cases the abused substance was a psychotropic available on the surgery facilities. However, 96.4% of the participants denied they could have a substance use problem, although 16.9% declared they had already used non prescribed psychotropics. Benzodiazepines were the most frequently used substances. In addition, 88.0% of them consider it was difficult to search for medical help. They added that a service exclusive for physicians would make this search easier. Nevertheless, 56.6% are not aware of the existence of such a service.

Conclusion: Non-prescribed psychotropic use was high. However, most part of the clinicians does not consider this a problem. Most of the professionals do not know programs on substance use disorders specific for physicians, what would be a very positive initiative according to great part of them.

The influence of social factors plays a very important part in nervous anorexia. There are many clues and data that lead us to this conclusion. Nervous anorexia can't be understood without noticing determined facts that begin and develop in society, surrounding the patients. The genetic, biological and endocrine facts, the secondary effects of the non-eating process, as well as the social factors, are gathered in this bio-axiological perspective that defines itself as integrative. This bio-axiological integration acquires significance in societies where success implies the adaptation of certain standards, almost forced by the media on the population.

CANNABINOIDS AND MONOAMINE OXIDASE ACTIVITY

INSTITUTIONS
1. Charles University in Prague, 1st Faculty of Medicine, Department of Psychiatry, Prague, Czech Republic

AUTHORS
1. Zdeněk Fišar, Dr., CSc, zfsar@lf1.cuni.cz

Aims: Mitochondrial monoamine oxidase (MAO) metabolises monoamine neurotransmitters which participate in the development of affective disorders, as well as in the side or therapeutic effects of cannabinoids. Therefore, we studied the effects of cannabinoids on MAO activity in synaptosomes.

Methods: The effects of Δ⁹-tetrahydrocannabinol (THC), anandamide (endogenous cannabinoid) and synthetic agonist of cannabinoid receptors WIN 55,212, on the activity of MAO (type-A or type-B) were measured in synaptosomes isolated from pig brains by means of ¹⁴C-labelled substrates (serotonin or phenylethylamine).

Results: Significant inhibitory in vitro effects of cannabinoids on the activity of MAO-A and MAO-B were observed at concentrations exceeding 10 μmol/l, while THC was a more effective inhibitor than anandamide and the inhibition was a competitive one. The inhibition caused by WIN 55,212 was significantly lower than that caused by THC and anandamide.

Conclusion: MAO activity is acutely influenced by cannabinoids only at relatively high concentrations of the drug. Our previous results indicate that such concentrations also cause the inhibition of serotonin uptake (1). The results support the hypothesis that direct action on monoaminergic neurotransmission can be involved in the effects of high doses of cannabinoids. The sensitivity of MAO to antidepressants, but also to nicotine and personality traits (2), makes it possible to consider the hypothesis that MAO activity can also be related to the interindividual differences in several effects of cannabinoids.

This research was supported by MSM0021620849 grant.

2. University of Lausanne, Faculty Of Psychology, Lausanne, Switzerland

AUTHORS
1. Pascal Gache, Mr., MD, pascal.gache@hcuge.ch
2. Brigitte Favre, Mrs.
3. Jérôme Rossier, Mr., PhD

Aims: The aim of this study was to evaluate alcohol addicts' emotional experience, and to identify which feelings they endure most during detoxification.

Methods: We interviewed 69 subjects: 38 alcohol addicts (ADs) of an inpatient program, and 31 matched controls. Each patient answered a selection of questionnaires twice, once at the beginning and once at the end of their hospital stay. The questionnaires were the Toronto Alexithymia Scales (TAS-20); the Positive and Negative Affect Schedule (PANAS); the State-Trait Anger Expression Inventory-2 (STAXI-2).

Results: After a week abstinence patients were less emotionally confused, less subject to intense angry feelings, less sensitive to criticism and were less likely to express their anger through aggressive behavior. Their general level of distress, improved considerably (1.3 times less intense), replaced by a high state of energy, concentration and positive engagements. Patients (76%) declared they drank to avoid their emotions (“anaesthetic function”). At the beginning of the stay, AD patients displayed high levels of anxiety and hostility, as well as strong feelings of guilt and shame. At the end of their stay, they were still sensitive to criticism (high tendency) and experienced superior levels of guilt and shame linked to events preceding their decision to go into care. It would be appropriate to help these patients tolerate frustration, increase their self-esteem, and, in order to decrease their feelings of guilt, undertake reparative actions.

Conclusion: The emotions of alcoholic patients are modified during detoxification with a decrease in anger and distressing feelings.

5. José Carlos Fernandes Galduróz, Dr., PhD, galduroz@psicobio.epm.br

INTRODUCTION: Goldstein (1987) showed that alcohol alters the environment of the membranes, mainly by modifying their permeability through the lipidic fraction. Ethanol changes the absorption and metabolism of polyunsaturated fatty acids (PUFAs).

OBJECTIVE: to assess a possible reduction of alcohol consumption through the association between naltrexone and PUFAs.

METHODOLOGY: This double-blind, double-dummy, randomized, placebo-controlled study involved 80 severe alcohol dependent male patients (DSM-IV). They were divided into 4 groups (20 patients/group) treated for 30 days as follows:

I - 50mg placebo (morning) and 2 capsules of liquid parafine (night).
II - 50mg naltrexone (morning) and 2 capsules of liquid parafine (night).
III - 50mg placebo (morning) and 1 capsule of Ω-6 and 1 of Ω-3 (night).
IV - 50mg naltrexone (morning) and 1 capsule of Ω-6 and 1 of Ω-3 (night).

We evaluated their amount of alcohol intake pre- and post-treatment.

RESULTS: The mean age ± sd was 42 ± 8; 30% were married. Their mean schooling was 8 years. Valid n was 18 (group I); 15 (II); 17 (III); 16 (group IV). The ANOVA showed significant differences when comparing themselves the baseline and after one month of treatment in three groups II, III and IV (p<0.0001). In the placebo group (I) there were no statistical differences.

DISCUSSION: PUFAs seem to be possible coadjutants in the treatment of alcoholism, since they can stabilize neuron membranes and act on the neural systems that were altered by the chronic use of this drug. However, further studies are necessary before one can reach more consistent conclusions.

ACKNOWLEDGEMENTS: This work was supported by FAPESP - Fundação de Amparo a Pesquisa do Estado de São Paulo.

5. Nelson Adami Andreollo, Dr.

Introduction
There are several reports of idiopathic achalasia misdiagnosed as anorexia nervosa (AN) in the literature

Case Report
We report a case of a 21-year-old woman, referred to the Eating Disorders Outpatient Program at the Universidade Estadual de Campinas, with diagnostic hypothesis of AN and weight loss of 22-kg in 11 months. Organic etiology had been previously excluded. The early symptoms were regurgitation during sleep, worsening to involuntary vomiting. She described that the vomits got worse when she was anxious. She demonstrated ambivalence on the perspective of nutritional recovery and affective dissociation when considering the consequences and risks of malnutrition. She was referred to another upper digestive endoscopy, an esophagogram and an esophageal manometry that confirmed the diagnosis of idiopathic achalasia. She was submitted to surgical intervention and postoperative recovery was very satisfactory without symptoms of AN.

Discussion
Differential diagnosis between AN and achalasia is not invariably so evident. Esophageal motility disorders have been reported in patients with diagnosis of AN, and the gastrointestinal symptoms frequently improve with refeeding. Besides, eating avoidance and self-induced vomiting have also been reported in patients with esophageal achalasia. In the case reported here, the absence of intention to lose weight and body-image distortion was initially neglected. Psychological and psychiatric were overestimated at the expense of clinical history and vomiting characteristics, leading to the initial misdiagnosis.

INTERNET ADDICTION, PREVALENCE AND EPIDEMIOLOGICAL FEATURES: FIRST STUDY IN IRAN

INSTITUTIONS
1. Babol Medical University, Department of Psychiatry, Babol, Iran (Islamic Republic of)

AUTHORS
1. Ali Ghabeli Juibary, Dr., MD, alighabeli@yahoo.com
2. Farzan Kheirkhah, Dr., MD, drfarzankh@yahoo.com
3. Arman Gouran, Mr., medicine82b@yahoo.com

Background and aims: The concept of Internet addiction, also called Internet addictive disorder or pathological Internet use, entered the medical lexicon in 1995. To investigate the prevalence of Internet addiction among northern Iranian Internet users and to explore the epidemiological features associated with Internet addiction, for the first time in Iran, this study performed.

Methods: A total of 1856 Internet user volunteers from Mazandaran province cities were surveyed using Farsi version of Young’s Internet Addiction Questionnaire during 2005-2006. Data analysis was done using the SPSS 13.0 Win Program for descriptive and correlational statistics.

Results: Total of 424 dependents was in our sample. The incidence rate of Internet addiction was 22.8%. Dependents spent an M = 14.42, SD = 13.74 hours per week compared to non-dependents who spent M = 9, SD = 10.37 hours per week (P < 0.001). The sample of Dependents included 256 males and 165 females (P < 0.001). Mean±SD of Income Used for On-line Service Fees was 30.11±25.27 percent in Dependent group and 18.90±20.79 in Non-Dependent group (P < 0.001). Dependents predominantly used the two-way communication functions available on the Internet like chat rooms (P < 0.001).

Conclusions: The present study suggests that Internet addiction is frequent among northern Iranian Internet users. In addition, chat rooms are most addictive web environment in this population. The results have important implications for further studies of prevalence, implementation of preventive measures, and the development of treatment approaches for Internet addiction.

BUPRENORPHINE (SUBUTEX®) SUBSTITUTION TREATMENT IN AUSTRIA: GUIDELINES FROM A PRACTICAL POINT OF VIEW

INSTITUTIONS
1. Medical University Innsbruck, Psychiatry, Innsbruck, Austria
2. Medical University Vienna, Psychiatry, Vienna, Austria

AUTHORS
1. Salvatore Giacomuzzi, Mr, salvatore.giacomuzzi@i-med.ac.at
2. Erika Jung, Dr, MD
3. Yvonne Riemer, Mrs, MD
4. Gabriele Fischer, Mrs, MD

Objectives: Substitution treatment has become a major intervention in the care and treatment of drug dependence in Europe. Buprenorphine has been proposed as a new therapy that could help those who are not already receiving treatment, help to stem the incidence of HIV and other diseases, and help alleviate other problems resulting from opioid abuse. In several studies buprenorphine was found to be nearly as effective as methadone and a useful alternative for maintenance therapy of opioid-dependent subjects. The presented work aims to introduce some guidelines for buprenorphine from a practical point of view within maintenance treatment.

Methods and results:
To calculate estimated dosages the following conversion factors could be used:

Methadone dosage = Subutex® dosage x 4.166
Methadone dosage = SROM dosage x 0.166

After a treatment period over 8 years we can present starting dosages and medication transfer guidelines which differ a bit from calculated conversion factors from a practical point of view could be established as follows:

General starting dosages
Methadone 20-40 mg

Buprenorphine 2-8 mg
SROM (slow-release oral morphine) 200 mg

Methadone to Subutex®
40 mg 8-14 mg
60 mg 14-20 mg
70 mg 16-24 mg
80 mg 24-30 mg

SROM to Subutex®
200 mg 16 mg
400 mg 24 mg

Heroin to Subutex®
0.5g/d 4-8 mg
1.0g/d 8-16 mg

Conclusions: According to these practical transition guidelines the appropriate buprenorphine (Subutex®) dosage can be estimated more easily and the maintenance phase can be reached when the patient is doing well on a steady dose of buprenorphine. The length of time of the maintenance phase is individualized for each patient and may be indefinite.

3. Selin Demir, Mrs.

Objective: The use of alcohol leads to various nutrition problems. Youngsters constitute the risk group for nutrition disorders based on alcohol use (1, 2). This study was conducted to analyze the state of alcohol use of Turkish university students according to their body mass index.

Method: The sample of the research consisted of 284 students who studied in Ege University in Turkey. Data was collected with the questionnaire form developed by researchers.

Results: 71.1% of the students were normal weight while 58% consumed the highest amount of carbohydrates, 51.1% had breakfast regularly, 53.9% dined three or more times a day and 78.9% did sports regularly. 65.5% of students consume alcohol and 39.4% consume 1-10 units of alcohol a week. 39.1% of students first consumed alcohol at the age of 16-19 and 51.4% consumed it first with friends. No meaningful difference has been determined between the body mass indices of students and their state of alcohol use (X² = 7.291, p>0.05).

Conclusion: The majority of students are consuming alcohol. The students' states of alcohol use do not differ according to their body mass indices.

CONTROLLED DRINKING PROGRAMS FOR AN IMPAIRED CONTROL DISEASE - AN APPARENT DILEMMA?

INSTITUTIONS
1. Hôpitaux Universitaires de Genève, Department of Community Medicine, Switzerland

AUTHORS
1. Sophie Haaz, Mrs., MD, sophie.haaz@hcuge.ch
2. Pascal Gache, Mr., MD

Aims - Impaired control is a central element in disease model of alcoholism. Some studies documented that a little percentage of alcoholics may live within the context of a controlled drinking pattern without an absolute abstinence necessity. Our objective is to investigate how established disease concepts question these empirical observations.

Methods - We describe and explore the diagnosis of dependence syndrome and its underlying disease concepts. We analyse recent studies on drinking behaviour control ability, described as a binary component - maintained versus lost, or on a linear scale. With reference to Rawls's reflexive equilibrium we attempt to dialogue between theory and practical focus.

Results - We support a model of addiction disease which allows a comprehensive integration of concepts and empirical observations. We analyze in parallel the lost of ability to control drinking and the theory of a psycho-social training model for regaining lost competences. The binary model of dependence syndrome seems reductive. It describes a severe disease, in which adverse consequences may already coexist and brings together a large inhomogeneous population. The treatment goals are also often ambiguous, in regard with the fact that abstinence or controlled drinking are a direct target or one of the way of obtaining a secondary main benefit - a better health.

Conclusion - We emphasize that continuing clinical and ethical research needs improving efforts in precision of disease concept reference, accurate treatment objectives and precise sub-population description. Better context referencing would help solving apparent conflicts and visibility problems.

HOW CAREGIVERS FAIL TO RECOGNISE AND COUNSEL DRINKING PROBLEMS AMONG HOSPITALISED PATIENTS

INSTITUTIONS
1. Hôpitaux Universitaires de Genève, Switzerland

AUTHORS
1. Sophie Haaz, Mrs., MD, sophie.haaz@hcuge.ch
2. Nicolas Wermelille, Mr, MD, nicolas.wermelille@hcuge.ch
3. Frederic Guillou, Mr, frederic.guillo@hcuge.ch
4. Richard Beauverd, Mr, MD
5. Pascal Gache, Mr, MD, pascal.gache@hcuge.ch

Aims - Despite high prevalence of alcohol use disorders in hospitalised patients, caregivers often fail to recognise and help. Our study's goal is to give an objective measure of how caregivers identify and help patients with alcohol problems.

Methods - We conducted a prospective observational study in general medicine wards. Patients were screened with the AUDIT questionnaire - a ten-item standardised screening tool for excessive drinking and dependence. Each patient's physician and nursing team were asked if they thought their patient had alcohol problem. In the case of a positive response, the caregivers were asked to describe the ways they used to identify and manage the problem.

Results - On a total of 680 hospitalised patients, 458 (67.4%) fulfilled inclusion criteria and gave consent to the study (231 males, 227 females). Mean age was 64.7 years. An "alcohol problem" was mentioned only in 2% as a reason for admission. Results from AUDIT confirm the high prevalence of alcohol problems (19.6%). Among all the patients detected with the AUDIT, doctors only detect 64.5% alcoholics and 28.8% excessive drinkers. Excessive drinkers without obvious clinical problems are rarely identified. The caregivers counselled 28% patients and referred 11% to a specialised consultation. They never used standardised questionnaires for screening alcohol problems and keep in mind some stereotypes of alcoholic patients as diagnostic criteria.

Conclusions - Caregivers may improve screening efficacy with using specific well validated questionnaires. They need to be trained to diagnose alcohol use disorders (especially excessive drinkers) and to propose specific interventions.

5. Dartiu Xavier da Silveira, Dr, PhD, dartiu@psiquiatria.epm.br

Aims/Objectives: On 90's decade, 50% of the notified cases of AIDS in the city of Santos were indicated as contamination form the sharing of the needles. Of the AIDS's cases in Brazil, 38% are women that catched the HIV virus because of the injectable drugs use or through sexual partnership of injectable drugs users (health ministry, 2000). This study aims to understand the use of injectable drugs among women that use injectable drugs in the city of Santos, Brazil.

Method: Qualitative study with assessment on two focal groups. Twenty usuary women participated being active or ex usuary of injectable drugs, that lived in the region.

Results: The women that were assessed are more than one drug's usuary. The syringes are obtained by their partners attached to the harm reducers. The women are not linked at the program, because the partners do not authorize them to participate of the program. This relationship makes abstinence attempt behave almost impossible. When they change sex for drugs, the sexual relationship is almost ever without protection.

Conclusions: The drugs reduction programs need to be developed with counseling techniques to practice protected sex and that the culture and gender questions like gerenators of vulnerability to sexual disease transmission and for AIDS.

Aims/objectives: The use of the internet has increased considerably over the last few years. With this soaring number of internet users, the problem of internet addiction has attracted high attention from psychiatrists, psychologists, educators, and the public. The purpose of this research is a study of internet addiction and mental health among students as new challenge in health psychology.

Methods: Research method is descriptive. Statistical population is all of students of Islamic Azad university- Sari- Branch. Statistical sample is 261 college students that were selected by using the random sampling method. Sample size estimate with use kerejci and Morgan table. In this research for gathering data questionnaire were used. In present study six hypotheses was tested. To analyze data, coefficient of correlation and, t-test have been used.

Results: Results of research showed that: 1) Students of university suffer to internet addiction (t=28.456, p<0.05). 2) Students of university uses from internet due to different reasons (14 reasons). 3) There is significant difference between internet addiction in male and female (t=4.267, p<0.05). 4) There isn’t significant difference between internet addiction in students of university with different ages (F=1.054, p>0.05).

Conclusion: Based on Results of research, Internet addiction is currently becoming a serious mental health problem among college students. Internet addiction as new challenge in health psychology needed to prevention and cure considerations.

Key words: Internet addiction, mental health, college students, health psychology.

Aims/Objectives: This study assesses whether everyday prospective memory (PM: memory for future events) is impaired by ‘binge drinking’ in a teenage cohort.

Methods: 100 students aged 16-19 years was accessed for the study. 40 were omitted from because they were using other illicit drugs (e.g. ecstasy) alongside alcohol. Of the remaining sixty, 26 were categorized as ‘binge drinkers’ - defined as someone who drank above 6 units for females and 8 units for males on 2 or more occasions per week. The other 34 participants were categorised as non-binge drinkers. Each participant completed the self-report Prospective and Retrospective Memory Questionnaire (PRMQ) - measuring everyday PM lapses (eg how often one forgets to post a letter on time), an objective video-based PM task - which requires the person to remember to carry out particular actions at particular locations when viewing the video clip of a city shopping area, a mood questionnaire - measuring anxiety and depression, and a Substance Use Questionnaire - which measured weekly alcohol use and other substance use.

Results: A MANCOVA comparing the binge drinkers and non-binge drinkers, incorporating age, anxiety and depression scores as covariates, was applied to the self-report and video PM data. After controlling for age, anxiety and depression, there were no significant group differences on self-reported PM lapses, but binge drinkers did recall significantly fewer location-action combinations on the video-based task, than non-binge drinkers.

Conclusion: The findings from the objective measure of PM indicate that deficits in everyday PM are associated with ‘binge drinking’ in teenagers.

**DOES PROLONGED USE OF MDMA OR ‘ECSTASY’ AFFECT EVERYDAY PROSPECTIVE MEMORY?**

**INSTITUTIONS**
1. Northumbria University, Psychology, Newcastle-Upon-Tyne, United Kingdom
2. Northumbria University, Psychology, Newcastle upon Tyne, United Kingdom

**AUTHORS**
1. Thomas M Heffernan¹, Dr., PhD, tom.heffernan@unn.ac.uk
2. Clive Bellis², Mr., BSc (Hons).

**Background:** Regular use of MDMA (“ecstasy”) is associated with self-reported long-term prospective memory errors (PM: memory for future events/actions) when compared to non-users (Heffernan et al., 2001; Rodgers et al., 2003). However, self-reports of memory are susceptible to a range of biases and need to be used alongside objective PM measures.

**Aims:** To compare ecstasy-users and non-users on both self-reported and objective measures of PM.

**Methods:** A quasi-experimental design was used, accessing 11 ecstasy-users and 9 non-users. Each participant completed the following: self-reported Long-Term Prospective Memory Scale and Strategy Scale measured by the Prospective Memory Questionnaire (PMQ) - which measures everyday PM lapses, an objective measure of PM was achieved using the Cambridge Test of Prospective Memory (CAMPROMT) - an objective and standardized clinical instrument that measures a person’s PM on time/event-based PM tasks, a self-reported Recreational Drug Use Questionnaire - measuring weekly use of ecstasy and other substances, and the Hospital Anxiety and Depression Scale (HADS) - which was used to measure mood.

**Results:** An ANOVA applied to the non-memory data revealed no significant group-differences on age, other drug use (alcohol was approaching significance), memory strategies, or mood. A MANCOVA, incorporating alcohol use as a covariate, was applied to the self-reported Long-Term PM and CAMPROMT data comparing ecstasy-users and non-users. The results revealed no significant group differences on self-reported long-term PM lapses. However, ecstasy-users did recall significantly fewer tasks on the CAMPROMT.

**Conclusion:** The results suggest ecstasy-users have impairments in everyday PM activities, but lack self-awareness of their memory problems.

**AUTHORS**
1. Thomas M Heffernan¹, Dr., PhD, tom.heffernan@unn.ac.uk
2. Terence O’Neill¹, Mr
3. Janice Bartholomew¹, Miss
4. Jon Ling², Dr., PhD

**Aims/Objectives:** Prolonged smoking has been associated with a variety of cognitive deficits, including impairments in memory. This study assesses whether smoking in teenagers impairs their everyday prospective memory (PM: memory for future events).

**Methods:** A non-experimental design was used. Thirty-eight smokers and 38 non-smokers were tested, all of whom were college/university students aged 17-19 years studying in the north-east of England. Each participant was asked to complete 3 tasks: a Prospective Memory Questionnaire (PMQ) - which is a self-rating scale used to gauge the number of everyday PM lapses experienced (e.g. forgetting to lock one’s door as one leaves the house), as well as measuring strategy-use, an objective video-based PM task - which requires the person to remember to carry out particular actions at particular locations when viewing a 10 minute video clip of a busy city shopping area, and a Substance Use Questionnaire - which measured weekly alcohol use and other substance use.

**Results:** A series of one-way ANOVAs revealed that the smokers were older, drank more alcohol and used more cannabis, than the non-smokers, with no difference on strategy use. A MANCOVA revealed that, after controlling for age, alcohol use and cannabis use, the smokers reported more lapses in their long-term PM and recalled less on the video-based PM task, than the non-smokers.

**Conclusion:** Self-reported and objective deficits in everyday PM are associated with smoking in teenagers.

Aims: It is known that dopaminergic neurotransmission is of crucial importance in the neurobiology of alcohol craving. Recent studies showed that the promoter-specific methylation of alpha-synuclein, which is important for dopaminergic neurotransmission, is altered in alcohol dependence. Aim of the present study was to investigate a possible association between promoter-specific DNA methylation of the dopamine transporter gene (DAT) and alcohol craving in patients with alcohol dependence.

Methods: Blood samples of 76 patients admitted for in-patient detoxification treatment were included in the study. We measured promoter-specific DNA methylation of the dopamine transporter using methylation specific quantitative real-time PCR. The extent of alcohol craving was assessed using the Obsessive Compulsive Drinking Scale (OCDS) which was administered at admission.

Results: As DAT promoter methylation was not normally distributed we ln-transformed the values to achieve normal distribution. Ln-transformed methylation of the DAT-promoter was negatively associated with the OCDS (linear regression: Beta=-0.275, p=0.016), particularly with the obsessive subscale (Beta=-0.300, p=0.008). Compulsive Craving was not associated with DAT promoter methylation.

Conclusion: Findings of the present study show that DNA-specific hypermethylation of the DAT-promoter may play a role in the neurobiology of alcohol craving. It can be hypothesized that hypermethylation of the DAT-promoter inhibits transcription and therefore expression of DAT and leads to elevated dopamine levels in the synaptic gap which seems to be associated with lower craving.

Aims/Objectives: The objective of this study was to assess differences between subjects dependent on methamphetamine (MAMP) and healthy volunteers in event related potentials (ERPs). We tested the hypothesis that subjects dependent on methamphetamine significantly differ from age- and gender-matched healthy volunteers in the visual mismatch negativity generation. Methods: We recorded ERPs in MAMP dependent individuals and a group of healthy controls in the visual mismatch negativity paradigm (vMMN). Results: The 17 studied subjects did not significantly differ from the 17 healthy volunteers in age, gender distribution or vMMN (P = N.S.; Wilcoxon Matched Pairs Test). The vMMN component of ERP in MAMP dependent individuals significantly degraded accordingly to the duration of abuse (Pearson correlation coefficient r = 0.59-0.62; p<0.05). Conclusion: Due to neurotoxicity of methamphetamine, MAMP dependent subjects are gradually becoming similar to patients with schizophrenia in psychopathology (psychotic symptoms) as well as ERP changes (MMN deficit).

Aims/Objectives: The risk of occurrence of psychotic symptoms in methamphetamine dependent subjects is eleven times higher than in the total population. Dopamine, one of the key neurotransmitters in etiopathogenesis of psychosis, is metabolized by catechol-O-methyltransferase (COMT). The Val158Met polymorphism of the COMT gene (22q11.21) changes the activity of the enzyme up to fourfold, thus influencing the dopamine activity in the human brain. We tested the hypothesis that individuals dependent on methamphetamine with psychotic symptoms differ from subjects dependent on the same substance without psychosis in genotype or allele frequency of the COMT gene Val158Met polymorphism.

Methods: Methamphetamine dependent patients treated at the Substance Dependence Treatment Unit in Nechanice who signed the informed consent were enrolled into the study. Psychosis was diagnosed according to the ICD-10 Classification of Mental Disorders (diagnoses F15.50 to F15.53). We assessed the COMT genotype using the polymerase chain reaction. Results: Eighty-three patients (25 women) at the age 18-38 years (median 22 years) dependent on methamphetamine for 1-13 years (median 5 years) entered the study. We detected psychotic symptoms in 18 patients (8 women). We did not find a significant association between the COMT genotype or individual COMT Val158Met alleles and occurrence of psychotic symptoms in methamphetamine dependent subjects (p=n.s.; Fisher’s exact test).

Conclusion: Our results may have been biased by assessment of males and females together, hidden ethnic stratification of the study sample, or gene-gene/environment interactions.

5. Richard Rokyta, Prof., MD, PhD

Our previous studies demonstrated that methamphetamine (MA) administered during gestation and lactation periods impair maternal behavior as well as the postnatal development of rat pups. Prenatal MA exposure affects behavior in rats even in adulthood. The aim of our study was to distinguish the extent of the drug-induced effect and the extent of the effect induced by impaired maternal care. Mothers were or were not daily exposed to injection of MA (5 mg/kg): prior to impregnation and throughout gestation and lactation periods. On postnatal day 1, pups were cross-fostered so that each mother received some of her own and some of the pups of mother with opposite treatment. Male offspring were tested for sensorimotor development in preweaning period by using tests: negative geotaxis, tail pull, righting reflex on surface, righting reflex in mid-air and rotarod. In adulthood, animals were tested for behavior in Open field and Elevated plus-maze. Our results demonstrated that prenatal as well as postnatal MA exposures impair sensorimotor development in all tests. In adulthood, prenatal MA exposure decreases locomotor and exploratory behavior tested in Open field. In some cases postnatal care of control mothers at least partially suppressed the negative effect of prenatal MA exposure. Thus, it seems that not only the drug per se but also the postnatal care may play a role in long-term consequences of drug abuse.

2. physician & psychoanalyst, Russian Federation

AUTHORS
1. Marina G. Chukhrova¹, mba3@sibmail.ru
2. Anton N. Savushkin²

Painful therapy into the corporally-focused psychotherapy has shown the efficiency at treatment addictions and other avitality (Chukhrova M.G. and al., 2005, 2006, and 2007). Have been revealed following mechanisms of a positive effect of painful influence:

1. There is activation of endorphins device.
2. The patient is trained to test and recognize the emotions during the moment of painful influence.
3. There is a switching an existing stereotype of functioning on more complex level caused by sharp short-term painful stress, thus the metabolism is transformed.

Painful stimulation destroys pathological programs in a brain, breaks off pathological conditioned-reflex communications, activates the central nervous system, especially emotions zone, and forms a new physiological condition with a new dominant - a sharp pain. Besides at painful therapy there is a restoration of mutual relations between hemispheres. During therapy the left hemisphere is activated, and inversion of reflection between hemispheres is restored. The pain is the stress factor, and it includes nonlinear multivariate mutual relations, interrupts braking reserve genes and connects not used resources of a brain. In reply to threat of a body damage there is an activation of a protective instinct. The physical pain dissolves a spiritual pain. The pain renders positive influence in depression. By us it is developed and is put into practice algorithm of carrying out of sessions of painful stimulation within the limits of the corporally-focused psychotherapy. We have developed and we put into practice algorithm of carrying out of sessions of painful stimulation within the corporally-focused psychotherapy.

Aim: Nicotine addiction is an important health problem increasing medical morbidity and mortality. There are three possibility related the mood disorder with smoking. Firstly, some have suggested that such persons use cigarette as means of self-medication of affective symptoms. The alternative possibility that regular nicotine use increases the likelihood of subsequent mood disorder. We investigated prevalence of smoking in bipolar patients.

Method: This case-control study carried out in Ilsanpaik Hospital, Korea included patients with a DSM-IV diagnosis of bipolar I disorder (N = 40) and a representative sample of the normal population (N = 130). Smoking history of bipolar patients was assessed with the Fagerstrom Test for Nicotine Dependence.

Results: The frequencies of ever smoking and current daily smoking were, respectively, 75% (30/40) and 53% (21/40) for the bipolar patients and 43% (65/150) and 33% (50/150) for the control group (respectively odds ratios [ORs] and 95% confidence intervals [CIs] were OR = 3.9, 95% CI = 1.8 to 8.6 and OR = 2.2, 95% CI = 1.1 to 4.5). The differences were significant (p = .01 and p = .029, respectively).

Conclusion: Although small sample size, this study suggests that smoking may be more prevalent in bipolar patients than in the normal population. In future, the additional studies related the epidemiology of smoking with mood disorder and other psychiatric illness is needed.

8. Vasiliki Basogianni\textsuperscript{1}, Mrs, ssknni@otenet.gr

Objectives
This presentation concerns the advantages resulting from the model of a Counselling Center providing prevention as well as treatment services.

Method
The Center was established in 1994 and was the first service in town providing prevention and treatment services through an outpatient drug counselling psychotherapeutic programme on an individual basis. Prevention interventions for students, parents, and groups from the community constitute the first phase of the contact between this population and the scientific team.

Results
Individuals who belong to high risk groups or have been involved in drug use, and parents who detect problematic behaviours or drug use in their children, have the opportunity to look for further individual interventions. The involvement of one Center and the same specialists in the prevention and treatment process facilitates immediacy and the possibility of approaching people without referrals. This ensures confidentiality, absence of competitiveness among services, detection of high risk groups and drug abuse behaviours, and participation of citizens in the preventive interventions, which results in the acceptance of the Center. The involvement of specialists in different activities increases their motive, has an educational function, and reduces the danger of “burn out”.

Conclusion
The shifting of the staff in different fields of interest gives them the opportunity to have a global perception of the drug abuse phenomenon, its causes and the changes which occur in the course of time. The use of this model reduces costs, since different services which cover big part of the community needs are offered by one service.

AN INSIGHT INTO THE TREATMENT OF ELDERLY ALCOHOLICS

INSTITUTIONS
1. Special Hospital for Addictions, Belgrade, Serbia and Montenegro

AUTHORS
1. Vesna Jovanovic-Cupic\textsuperscript{1}, Dr, MD, cupic@drenik.net

As a part of low-demand programmes of the Belgrade Special Hospital for Addiction, a programme for treating elderly alcoholics has been developed, within a greater goal of harm reduction. With a global trend of longer life expectancy, elderly alcoholics increasingly become a more numerous category of patients. Due to the lack of social control, neglect by the family, and a mixture of alcohol-related health problems and age-related problems, this category of patients are not easy to diagnose, and therefore they persist as invisible alcoholics for longer periods of time. Moreover, even their own children often do not properly realise the seriousness of their parents’ condition. The programme is therefore based on: educating the elderly alcoholics’ children on the problem of alcoholism, support to patients’ abstinence, support in overcoming the hardness of getting retired, helping them to structure their free time, developing their diet, and supporting them in taking over their family roles and responsibilities.

Objective: To compare drug use among anesthesiologists and general practitioners in a Brazilian University Hospital. Methods: This is a cross-sectional study with the application of a social-demographic and drug use pattern questionnaire in the last 30 days and last 12 months. Interviewees were 178 anesthesiologists and general practitioners in the university hospital of the Federal University of São Paulo, Brazil. Only one physician has refused to participate of the interview. Statistical-descriptive analysis was conducted and comparison with qui-squared test and p<0.5 was considered for significant differences. Results: From the 178 physicians, 53.4% were anesthesiologists (n=95) and 46.6% (n=83) were general practitioners. There were no significant differences in relation to gender, age and marital status. There were no significant differences in relation to use of alcohol, hallucinogens, anticholinergics, tranquilizers, opioids, barbiturates, anabolizants in life, last 30 days and last 12 months. Anesthesiologists have higher prevalences of life use of tobacco, cannabis, cocaine, amphetamines, solvents, halogens and designer drugs. Conclusion: In this study, Brazilian anesthesiologists have higher prevalences of drug use when compared to general practitioners, such as international references.

6. David A Mrazek1, Dr., MD
7. John L Black1, Dr., MD

Objective: This study investigated effects of genetic variations and clinical characteristics of alcohol dependence on the development of alcohol withdrawal seizures (AWS) and delirium tremens (DT). Methods: Clinical and demographic information was collected in 116 alcohol dependent subjects with a history of AWS and/or DT (cases) and 101 alcohol dependent subjects with a history of alcohol withdrawal without AWS and/or DT (controls). Genotypes at 12 candidate loci were analyzed in 204 DNA samples (112 cases and 92 controls). Main effects of the genomic and clinical characteristics and interaction effects were investigated using logistic regression models. Results: Study groups were similar in demographic characteristics. The case group reported higher intensity of alcohol withdrawal, higher alcohol consumption and greater tolerance compared to the control group. We found a significant interaction effect of SLC6A4 promoter polymorphism and DRD2 Ex8+246 SNP on AWS and/or DT history (p=0.009), but no strong main effects of these variations. Since maximum drinking tolerance was related to the history of AWS and/or DT, we adjusted for this covariate in analyses of genetic effects. Post-hoc analysis adjusted for maximum drinking tolerance revealed an even stronger association of the SLC6A4-DRD2 interaction with DT (p=2.8×10^-5), but no association with AWS. Conclusion: This is the first study revealing decreased likelihood of DT in alcoholics that carry at least one DRD2 Ex8+246 G allele and have the SLC6A4 LL genotype. It also provides direct evidence to support the search for gene-gene interactions even when strong main effects are absent.

5. Won-Ho Kim⁵, Dr., PhD

Dopamine reward pathway projecting from ventral tegmental area to nucleus accumbens is well known as playing an important role in alcohol dependence. It is supposed that this dopamine pathway is modulated by 5-HT, nervous system, and it was reported that ondansetron (OND), 5-HT₃ receptor antagonist, reduced drinking amount and increased abstinence rate in alcohol-dependent patients. The purpose of this study is to investigate the effect of combination of OND and naltrexone (NTX), non-specific opioid receptor antagonist, on alcohol intake in C57BL/6 mice. In 40 C57BL/6 mice in the state of alcohol dependence, vehicle, while OND 0.01 mg/kg, or NTX 1.0 mg/kg administrated respectively, or OND 0.01 mg/kg and NTX 1.0 mg/kg administrated simultaneously for ten days, medication effects on 2-hours alcohol, 22-hour water, 24-hour food intake and body weight were studied. When vehicle group was compared with 3 medication groups respectively, using a repeated measure ANOVA, NTX alone and vehicle groups showed a significant medication by time interaction (p=0.042) in 2-hour alcohol intake, but in the other 2 groups, OND and NTX combination group and OND alone group, there was no significant interaction with vehicle group in 2-hour alcohol intake. From these results, it is suggested that there is no effect on alcohol intake in mice treating with OND, and naltrexone’s suppression effect on alcohol intake in mice is attenuated when treating with OND and NTX simultaneously. It is supposed that a further study looking at the interactions of serotonin, dopamine and opioid nerves systems will be needed.

1. Levent Kirisci¹, Dr., Ph.D., levent@pitt.edu
2. Ralph Tarter¹, Dr., Ph.D., tarter@pitt.edu
3. Ada Mezzich¹, Dr., Ph.D.
4. Michael Vanyukov¹, Dr., Ph.D., mmv@pitt.edu

Objective: Employing a prospective paradigm, this investigation derived the childhood phenotype and the environtype associated with risk for cannabis use disorder.

Methods: Two hundred and sixteen boys were evaluated at age 10-12 on a comprehensive protocol using self, mother, and teacher reports and followed up at age 19 and 22 to determine the presence of cannabis use disorder. The transmissible liability index (TLI) and non-transmissible environment index (NTEI) were derived using item response theory. Logistic regression was conducted to evaluate the accuracy of the indexes, singly and in combination, to predict cannabis use disorder.

Results: The TLI and NTEI together predicted with 70% and 75% accuracy cannabis use disorder manifest by age 19 and age 22. Sensitivity was respectively 75% and 75% at ages 19 and 22.

Conclusion: The TLI and NTEI, capturing the individual and environment components of risk, provide the framework to screen the population from which youths having high susceptibility can be targeted to receive interventions to prevent cannabis use disorder.

DUAL DIAGNOSIS. COINCIDENCE OF ADDICTIONS AND PERSONALITY DISORDERS IN RUSSIAN CULTURE

INSTITUTIONS
1. Novosibirsk Medical University, Psychiatry, Novosibirsk, Russian Federation

AUTHORS
1. Tsezar P. Korolenko†, Mr., Prof., MD, PhD, lengyel@irs.ru
2. Inna A. Zrazhevskaya†, Mrs., MD, PhD, lengyel@irs.ru

The goal of this study was to provide the psychodynamic analysis of the patients with dual diagnosis consisted in the simultaneous coincidence of addiction and personality disorder. This category of patients is observed more and more often by psychiatrists and clinical psychologists in the large cities in Russia. They are recruited from the areas of postmodern culture. The enclaves of postmodern culture coexist with the structures of traditional and modern society. The challenge of postmodern psychology express itself in the “no time” phenomenon, in the high mobility of people, the mobility of such symbols as words and visual images; cultural pluralism and cultural changes. The relationships between people become multiple, and at the same time superficial. The dual diagnosis in patients was presented by the coincidence of different personality disorders and various addictions. The personality disorders (according to DSM-IV-TR) included borderline, antisocial, narcissistic (cluster B), and avoidant (cluster C). Addictions were represented both by chemical and non-chemical forms. Chemical forms included alcohol and drug addictions. Non-chemical forms included pathological gambling, sexual addiction, overeating, self-injury, and workaholism. The psychodynamic analysis revealed that psychological structure of observed patients contained the common to all addictions psychological addictive mechanisms. The emotional detachment and the absence of spirituality was typical. Established psychological dysfunctions were combined with the symptoms of the personality disorder. Psychodynamic therapy oriented on enhancing of the mentalization, creating the awareness of others’ mental states and strengthen the impulse control is proposed.

TREATMENT OF OFFENDERS WITH SUBSTANCE USE DISORDERS - LESSONS LEARNED IN CALIFORNIA IN THE LAST DECADE

INSTITUTIONS
1. University of California San Diego, Psychiatry, La Jolla, United States

AUTHORS
1. Igor Koutsenok†, Dr., ikoutzenok@ucsd.edu

Over the last decade, California has been a leader in implementing a variety of treatment programs for offenders with substance use disorders in prisons and community settings. Evaluation studies of prison based therapeutic communities followed by community-based continuum of care have consistently demonstrated their effectiveness at reducing recidivism and relapse to drug use. The lecture will focus on existing policies and strategies to treat substance use disorders in offenders, most common challenges in developing effective treatment strategies for this population, as well as the most recent treatment outcomes. The lecture will also review the successful strategies to integrate treatment intervention into criminal justice environment.

PSYCHOSOCIAL CONTEXT OF MARIJUANA USE IN CZECH ADOLESCENT POPULATION

INSTITUTIONS
1. Charles University, Psychiatric Clinic, Prague, Czech Republic
2. Prague Psychiatric Center, Prague, Czech Republic

AUTHORS
1. Frantisek David Krch
2. Ladislav Csémy

Authors refer on risks of using cannabis among pupils of 8th and 9th grade of basic schools and students of 3rd and 4th grades of eight-year grammar schools in Prague and České Budějovice. 17.3% of 1431 adolescents in an average age of 14.5 years reported an experience with marijuana or hashish during last year. Between the age of 14 and 15, an experience with cannabis increased from 12% to 22%. 7.7% reported regular (once a month and more often) use of cannabis. A higher prevalence of cannabis use was found among Prague adolescents; no significant difference was found between boys and girls. In comparison with their peers users of cannabis spent more often their leisure time in a bunch, they went out for entertainment in the evening more often, they had higher pocket money, they spent less time with their parents, they had conflicting relationship with one of their parents, more often they reported that one of their parents had problems with alcohol. They smoked, drank alcohol and had an experience with other drugs more often. In Windle’s questionnaire they showed higher score in a scale of attention disorder and hyperactivity, opposing disorder and behaviour disorders. Also a higher score of anomie and depression was found.

Supported by MZ001C2005.

Aim: Young generation spends more and more time using internet and addiction to it seems to be an increasing problem. In the context of social life each addiction, including internet addiction is a destructive attachment, which leads to functional disturbance in relationships with other people, strengthens suffering and loneliness.

The objective of this study was to show influence of the internet overuse on human relationships and displaying network addiction features in young generations. Out of the group of 100 students 68 daily internet users aged 19 to 24 were examined. An anonymous inquiry containing 28 questions was used. The inquiry was constructed basing on available tests checking internet addiction and authors’ observations. Age, sex and place of residence were taken into account as the characteristics of the examined group. The examined population included 10 males and 58 females, 57 of them lived in the cities, 11 of them in the villages.

Results: The results showed that internet overuse is a reason for family conflicts in 50% examinees, due to long term stay on-line young people have problems in learning, work, and family duties, on-line stay above 5 hours a day may be followed by an increased risk of addiction.

Conclusion: Prolonged internet use influences reduction of contacts with real friends.

4. Woong Cho¹, Dr., MD
5. Young-Bok Ahn², Dr., MD
6. Han-Cheol Yoon¹, Dr., MD

OBJECTIVE: Methamphetamine has been well known to cause mainly mental problems in humans, but only little is known about physical problems. In clinical settings, methamphetamine abusers often complain that their bones are brittle and broken easily. But there hasn’t been substantial data to back this up. We evaluated the frequency of osteoporosis in a group of hospitalized Korean men with methamphetamine abuse.

METHOD: The subjects were hospitalized male patients in Bugok National Hospital who met the DSM-IV criteria for methamphetamine abuse or dependence (n = 46, ages 41.33 ± 7.61, duration of use (years) 14.35 ± 7.35). Bone mineral density (BMD) was measured at lumbar spine by dual x-ray absorptiometry (DEXXUM3). Osteoporosis was a T-score ≤-2.5 SD and osteopenia was a T-score ≤-1, which were defined according to the criteria of the World Health Organization (WHO).

RESULTS: Mean BMD (g/cm², 0.71 ± 0.07) was lower in methamphetamine abuser group than in the general Korean population [Z score -1.96 ± 0.45]. When the WHO threshold was applied, frequency of osteoporosis was 21.74%, and osteopenia was 76.09% at lumbar spine.

CONCLUSION: There was considerable loss in bone mineral density in methamphetamine abusers. Our research shows that methamphetamine abuse has chronic effects on bone mineral density. The results may be meaningful in that it is the first clinical study to determine frequency of osteoporosis in male patients with methamphetamine abuse. An additional case-control study that includes important background variables for BMD such as height and weight is required.

OPIOID DEPENDENCE IN ABORIGINAL PEOPLES OF NORTH CHINA AND FAR EAST OF RUSSIA

INSTITUTIONS
1. Khabarovsk Medical Academy, Chair, Khabarovsk, Russian Federation

AUTHORS
1. I. P. Loginov¹

Objective of present investigation is to analyze of influence of socio-cultural factors on formation of opioid dependence in representatives of aboriginal subpopulations of Far East and North China with opioid dependence. 388 patients with opioid dependence were examined; from them 219 persons were ethnic Chinese living in North-Chine province Khaylunzyan and 169 patients with opioid dependence, inhabitants of Far East of Russia. Aboriginal Chinese group living in Russia was characterized by weakening influence of cultural factors. Informal observing of religious and national traditions in microsocial environment has been noticed in 60.9% of inhabitants of China and 30.8% Chinese-inhabitants of Russia, formal - in 16.3 and 6.8%, respectively; absence of religious and national traditions - in 22.8 and 62.4% of ethnic Chinese living in different countries. In both samples in groups where any observance of ethnocultural traditions was absent, antisocial actions have constituted 24.6 and 56.0%; convictions with compulsory treatment - 14.7 and 8.5%, respectively. Observance of national traditions is a constraint in relation to formation of opioid dependence in both ethnic samples but was not a factor conditioning motivation for refusal from drug consumption. Upbringing in the atmosphere of informal observance of religious traditions of Buddhism and Confucianism has an ambiguous influence on dynamic of opioid consumption and more seldom preceded to opioid consumption and opioid dependence formation.

PROMISING FUTURE WITH HIGH DOSES OF BACLOFEN IN SEVERE ALCOHOLISM

INSTITUTIONS
1. University Hospital of Geneva, Community and Primary Care Medicine, Geneva, Switzerland

AUTHORS
1. Dionysios Makris1, DR, Dionysios.Makris@hcuge.ch
2. Sophie Haaz2, DR, Sophie.Haaz@hcuge.ch
3. Carole Frei-Paris1, DR, Carole.Frei@hcuge.ch
4. Pascal Gache1, DR, Pascal.Gache@hcuge.ch

Objectives of the study: Baclofen is a potent GABAB receptor agonist. At the low-dose of 30mg/day (approximately 0.5mg/kg), oral baclofen has been shown to promote abstinence, reduce alcohol craving and consumption. In rats, high-doses of baclofen (3mg/kg) suppress alcohol craving. Our hypothesis lies on that high-dose of baclofen could help alcohol dependent patients with multiple failure therapeutic attempts to achieve abstinence.

Method: We performed an open-labeled study with high doses of baclofen (3mg/kg) for a period of 26 weeks. We included patients with long history of alcohol dependence and numerous attempts of treatment without significant improvement. Baclofen was given progressively to patients until the optimal steady dose (maximum of 3mg/kg). In case of adverse effect, progression was stopped temporarily or definitively.

Results: 12 patients participated to this open labeled study, they were 7 females, the mean age was 49.83 (± 5.9). The longest period of alcohol abstinence during the year previous to the study was 8.58 weeks (±12.7). The average alcohol intake at time of inclusion was 115g pure ethanol/ day. The maximum average dose of baclofen was 2.41mg/kg/patient (± 0.98) and the maintained dose was 2.10mg/kg/patient (±1.1). After 6 months, the number of consecutive days without drinking since the beginning of baclofen was 138.0 days (±117.0) and the number of excessive drinking during the follow-up period was 2.2 days (±4.4).

Conclusion: High doses of baclofen are globally well tolerated and seem to be an effective treatment of alcohol dependence for patients non presenting sedation as a baclofen's side effect.

NEW INSIGHTS ON THE USE OF BENZODIAZEPINES IN THE TREATMENT OF ALCOHOL WITHDRAWAL

INSTITUTIONS
1. Stanford University, Psychiatry & Behavioral Sciences, Stanford, CA, United States
2. Cornell University, Psychiatry & Behavioral Sciences, New York, NY, United States

AUTHORS
1. John O Brooks3, Dr, MD, johnbrooks@stanford.edu
2. Jose R Maldonado1, Dr, MD, jrm@stanford.edu
3. Long H Nguyen1, Dr, MD, jlhnguyen@gmail.com

Objective: Despite the frequent use of benzodiazepines for the treatment of alcohol withdrawal, studies comparing the efficacy of long and short half-life benzodiazepines in the treatment of alcohol withdrawal have shown mixed results. This study compared the effects of lorazepam to those of diazepam in vital signs and the Revised Clinical Institute Withdrawal Assessment for Alcohol scale.

Method: Patients (n=47) presenting with alcohol withdrawal symptoms were randomly assigned to either a lorazepam (n=24) or diazepam (n=23) treatment protocol at the time of admission. Primary outcome measures consisted of the Revised Clinical Institute Withdrawal Assessment for Alcohol scale, administered three times per day, and corresponding vital signs recorded throughout the length of their hospital stay.

Results: The average rates of change of CIWA-Ar scores and systolic blood pressure measurements and total benzodiazepine use were computed for each patient. There was no significant difference between the rates of change for either group on either measure (P>0.05). Similarly, there was no significant difference in the total benzodiazepine usage between groups (P>0.05).

Conclusions: This study did not reveal any evidence of a clinical advantage for choosing benzodiazepines according to their half lives. Our findings suggest that the choice of benzodiazepine in the management of alcohol withdrawal is not as critical as has been anecdotally assumed. Even though the findings of this study do not suggest a difference between class of benzodiazepine, it does highlights the benefits of close symptom monitoring and early intervention of patients at risk or undergoing alcohol withdrawal.

Background: DSM or ICD categorical classifications of alcohol use disorders have clinical convenience. However, alcohol dependence remains heterogeneous and probably encompasses a number of disorders of varying causes. Numerous multi-dimensional typologies of alcoholism have been suggested.

Method and sample: As a contribution to the categorical-dimensional debate, we aggregated descriptive data of almost 2000 DSM-III-R alcohol-dependent patients involved in clinical trials in six European countries (UK, Belgium, Switzerland, Austria, Portugal and Germany). Fourteen cluster internal criteria were selected among five domains considered useful in typologies: alcohol consumption, pattern of drinking, medical condition, physical consequences, and social consequences.

Results: Two subtypes were identified and nine criteria were shown to have the strongest discriminant validity. They mostly correspond to alcoholological and clinical characteristics of severity. Validity was confirmed with external criteria as well as outcome measurement.

Discussion: Our results are consistent with the intention to consider at least severity in the dimensional approach in the revision of the DSM classification. On the contrary of typologies in general population, subtypes in clinical samples can’t pretend to any etiopathogenic purpose. However, this axe of research in patients in care has immediate interest for better treatment matching.

Background: Chronic misuse of alcohol is associated with impairment of cognitive functioning. Decreased performance in alcoholics may be related to biological and psychological stress in early abstinence.

Objective: The effect of four-week abstinence on global cognitive functioning and depression among alcoholics were examined.

Methods: A total group of non-cirrhotic male primary alcoholics, without malnutrition, (N=86) aged from 20-60 (mean 43,4) years was consecutive recruited during inpatient treatment. They meet ICD-10 criteria for alcohol dependence and were compared with 30 matched healthy male controls (mean 43,3 years). Assessment of depression (HAMD, Hamilton, 1960) and cognition (Mini Mental Scale-MMSE, Folstein, 1975) were performed for alcoholics average three days after admission (HAMD-1, MMSE-1) and compared with controls (HAMD-c, MMSE-c). After four weeks assessment was repeated for alcoholics (HAMD-2, MMSE-2). Differences between groups were tested by Student t-test.

Results: There was significant difference between MMSE-1 and MMSE-c score, and MMSE-1 vs. MMSE-2, without difference between MMSE-2 and MMSE-c. All values were between normal ranges. Score on HAMD-1 was 15,37 vs. 7,35 on HAMD-2 and 1,43 on HAMD-c with significant differences.

Conclusions: In early four-week abstinence alcoholics showed non-clinical, but significant improvement of cognition functioning. Depression was mild, but more prominent in comparing with healthy controls. Cognitive and depressive symptom may be transient and may resolve at alcoholics. They need repeated assessment after early abstinence.

6. S. Martínez-Formoso
7. M. Arrojo-Romero

Objectives: Several studies have shown temperament and character profile of women with bulimia nervosa to be different from those of women with other eating disorders or healthy control women. The aim of this preliminary study is to assess the personality characteristics of a sample of bulimic outpatients seen at an Eating Disorders Unit.

Method: The revised version of the Temperament and Character Inventory was administered to 27 bulimic women and to 38 healthy controls. Both groups were matched by age and instruction.

Results: Compared to healthy controls, bulimics show higher mean scores in the areas of harm avoidance (116.96 vs. 103.21; p < 0.01) and self-transcendence (69.07 vs. 57.50, p < 0.01), and lower mean scores in self-directedness (117.37 vs. 148.18; p < 0.01).

Conclusions: As in other studies of women with bulimia nervosa, we have found higher levels of harm avoidance and lower self-directedness in these patients than in healthy control women. In contrast with previous reports, there were no significant differences with the global score of novelty seeking in our sample. These characteristics could be relevant towards prognosis because of their relationship with the response to pharmacologic and psychotherapeutic treatment.

MINNESOTA MODEL AND ALCOHOL DEPENDENCE: WHICH PERSONALITY TRAIT IS ASSOCIATED TO RETENTION IN TREATMENT?

INSTITUTIONS
1. Catholic University of Rome, Psychiatry, Italy

AUTHORS
1. Giovanni Martinotti
2. Marco Di Nicola
3. Daniela Tedeschi
4. Laura Monti
5. Marianna Mazza
6. Gino Pozzi
7. Luigi Janiri

Aims. Aims of our study were to evaluate the temperamental and character traits predictive of retention in a type of treatment performed with the Minnesota Model and to investigate the outcome of subjects after a self-help group treatment in relation to temperamental and character dimensions in order to highlight the presence of factors predictive of treatment outcome.

Methods. 104 detoxified patients with diagnosis of Alcohol Use Disorder (DSM-IV) were consecutively recruited. After detoxification, all the patients were included in a group treatment according to the Minnesota Model. Temperament and Character Inventory Personality Profile; abstinence from alcohol was regularly evaluated during the study.

Results. The temperamental dimension of Persistence (P) was found to be higher (p< .05) in the "alcohol free" group whereas the character dimension of Self Transcendence (ST) resulted to be lower. (p< .05) with respect to the group of relapsed subjects. P was found to be positively correlated to the number of accesses to the group treatment.

Conclusion. This is the first study to evaluate the personality dimensions involved in the decision of taking part to a psychosocial group treatment and the retention degree in treatment. The presence of a significantly higher level of Persistence reflects the importance of motivation and determination to remain sober and to continue to attend the group; Self Trascendence, significantly lower in the group with negative outcome, is probably a factor of lower adherence to a project such as the maintenance of sobriety.
P-01-077
HOSPITAL PSYCHIATRIC MORBIDITY ASSOCIATED WITH DRUG USE [ICD-9, Cod.292, 304, 305]. A DESCRIPTIVE LONGITUDINAL STUDY (SPAIN, 1979-2004)

INSTITUTIONS
1. Agency for Health Technology Assessment, Institute of Health Carlos III, Madrid, Spain
2. University of Alcalá Faculty of Medicine, Health Sciences and Social Medicine Department, Madrid, Spain

AUTHORS
1. Alvaro Medel-Herrero¹, Mr., alvaro.medel@isciii.es
2. Antonio Sarria-Santamera¹,², Dr., asarria@isciii.es

AIMS/OBJECTIVES: Longitudinal description of hospital psychiatric morbidity associated with drug use (drug-psychoses [ICD-9, Cod.292], drug-dependence [ICD-9, Cod.304], nondependent abuse-of-drugs [ICD-9, Cod.305]) in Spain, 1979-2004. Spain shows one of the highest drug use indicators in the world. Morbidity evolution reflects worrying trends in order to deal with mental health problems in the immediate future.

METHODS: A descriptive study, 26-year time (1979-2004). Assessment of national hospital utilization databases: CMBD-EMH. Age and sex adjusted hospital indicators were obtained and analysed. Hospital morbidity indicators obtained: admission, readmissions, total stays, averages stays, time intervals during the hospital stay, timely assisted prevalence and cause for discharge. Analysis of time cycles and the age distribution of admission and stays.

RESULTS: Rates were much higher for males than for females. Until 1992 the admission rate for drug-dependence [ICD-9, Cod.304] suffers a major increase. Since 1992 that rate start a decrease. In 1992 the admission rate per 10,000 inhabitants for Drug-psychoses [ICD-9, Cod.292] begins an extraordinary increase. Nondependent-abuse-of-drugs [ICD-9, Cod.305] follows a moderate increasing trend. In 2004 the admission rates of male patients reach the following values: Drug-psychoses (0.933); Drug-dependence (1.433); Nondependent-abuse-of-drugs (0.752). All of them account for 11% of hospital admission and 5% of stays for all psychiatric disorders. The average stays suffer a moderate decrease in the first half of the study period and keep stable in the second half. The average age of admissions shows a strong increasing trend. The rate of readmissions per calendar-year is one of the highest values occurring in mental health. Analysis of time cycles and age distribution of admission over the time series show relevant patterns of drug use.

CONCLUSION: Those conditions show a high hospital utilization in Spain. It is remarkable that although a decrease in admissions for Drug-dependence [ICD-9, Cod.304], admissions for Drug psychoses [ICD-9, Cod.292] are increasing.

The goal of research is factor estimation which has influence on the length of abstinence in psychoactive substance-dependents. Research method: We used the following techniques and tests: interview, test of basic outstanding leans (BOL), TCI-9 and NEO-PI-R. The results of this research are pointed on factors which have influence on the length of abstinence: family support, motivation for treatment, personal structure, efficiency and kind of defense mechanism. At the beginning of a treatment, family support and motivation for treatment have a special significance for treatment efficiency. After beginning of abstinence, a particular significance for its length has personal structure, efficiency and kind of defense mechanism. In this case, advanced level of psychological personal organization and presence of rationalization as defense mechanism cause length of abstinence. According to that, rationalization allows abstinent because its represents fair of losing an object. In actual moment that fair is real. Its manifestation is in form: „If I take drugs, he (she) will leave me and I will stay alone.” This rationalization we called positive rationalization. Based on our results a husband is on the top of positive rationalizations. Conclusion: Family support and motivation for treatment are necessary for succeed in dependents treatment. Special importance has positive rationalizations as defense mechanism, because these actualize fair of losing an object and on that way contribute the length of abstinence. Key words: dependent, abstinence, fear.

SOCIAL-DEMOGRAPHIC CHARACTERISTICS OF ALCOHOLIC AND NON-ALCOHOLIC FAMILIES - COMPARATIVE ANALYSES

INSTITUTIONS
1. Institute of Mental Health, Serbia and Montenegro

AUTHORS
1. Ivica R Mladenovic¹, Mr, MD, dr_im@verat.net

Background: Alcoholism is a social medical illness with consequences to all members of alcoholic family and all spheres of family life. We have choose family with adolescent (age 15-18), having in mind that adolescence is most vulnerable, but at the same time one of the most important periods in psychosexual development of personality.

Aim: The aim of our research is to find out whether there is a statistically relevant difference between alcoholic and non-alcoholic family in relation to particular social demographic variables.

Method: Sample is made out of 186 informants (62 whole families with adolescent) who are based on discriminative variable - alcoholism in family- divided in experimental and control group. In our research we have used following instruments: social demographic questionnaire, AUDIT, KOG-3 (Cybernetic IQ tests battery), as well as adequate statistical methodology for data processing.

Results: Some of the most important results are: lower level of religiosity (p<0,01 between alcoholic and men from control group); members of alcoholic families consider their parents marriage to be worst then control group (p<0,001 between adolescents from two groups). Members of non-alcoholic families are satisfied with their jobs and are in a better financial situation then members of alcoholic families (p<0,01).

Conclusion: We can conclude we got lower scores in alcoholic families in almost all examined variables. Destructivity of alcoholism in family could be seen also in social demographic sphere, in the case of alcoholic as well as in the cases of other family members.

Keywords: alcoholism, alcoholic family, adolescence, social demographic characteristics

2. Wlodzimierz Samborski², Prof., MD, PhD, ewamojs@amp.edu.pl

Simplex obesity is the most often kind of obesity which appears in group of children and adolescents. Lower physical activity coexists to obesity in this group of patients. The main reasons of the obesity are: environmental factors, genes, and psychological connected to schema of reaction for stress, quality of processes of coping, learning abilities, stage of personality development, self-esteem etc.

The aim of the study was to estimates types of coping with stress, level of fear and health habits in adolescents with obesity. 60 patients aged 13-16 yrs of age with obesity - BMI over 27 participated in the study.

Results: The results show significant correlation of negative health behaviors and the results of CISS. There was also the correlation on p. 0,05 between fear as a state and obesity. Adolescents with obesity had lower health behaviors in comparison to norms in population. Results show the necessity of psychotherapy oriented to improvement of coping and education toward good health habits and behaviors.

SEVERE LIFE EVENTS AND POST-TRAUMATIC STRESS DISORDER AMONG OPIATE DEPENDENT PATIENTS

INSTITUTIONS
1. Faculty of Medicine and Health Sciences, UAE University, Psychiatry, Al Ain, United Arab Emirates

AUTHORS
1. Hamdy Fouad Moselhy¹, Dr, MD, MRCPsych, hamdy.fouad@uaeu.ac.ae

Objective: The aim of this study was to find the prevalence of PTSD in opioid dependence patients and the relationship of post-traumatic stress disorder to the severity of dependence on opioid in patients attending the out patient clinic of drug treatment service.

Method: An interview with the Maudsley Addiction Profile (MAP), the Severity of Dependence Scale (SDS), Impact of Events Scale (IES) and ICD 10 clinical criteria was conducted in a substance-misuse outpatient clinic in Birmingham. Seventy patients with opioid dependence syndrome were interviewed.

Results: On interview, 30% of the patients’ sample met ICD 10 criteria for posttraumatic stress disorder. The mean number of traumatic events was 1.3, SD=1.5 (0-5 events). The number of patients who were exposed to sexual abuse in childhood was 17 (24.3%). The number of patients exposed to physical abuse was 19 (27.1%). The number of patients who witnessed parental physical fights was 20 (28.6%). The mean age of first exposure to trauma was 8.5 years. The main traumatic experiences in adulthood were mainly rape (5.7%) and severe physical injuries to self, (road traffic accident or physical assault) 20 (28.6%). The average age of second exposure to trauma was 19.6 years. Clinically significant levels of intrusive (45.7%) and avoidant (65.7%) symptoms were reported.

Conclusions: As in other samples the co-morbidity of PTSD and opiate use is much more common and warrant further study in the area of aetiology and management.

THE ABUSE OF CORTICOSTEROIDS AMONG IRAQI FOR WEIGHT GAIN PURPOSE IN BABYLON, IRAQ: A UNIQUE EXPERIENCE

INSTITUTIONS
1. Faculty of Medicine and Health Sciences, UAE University, Psychiatry, Al Ain, United Arab Emirates

AUTHORS
1. Ali Aburahman Younis¹, Dr, FRCPsych, aryonnis@hotmail.com
2. Hamdy Fouad Moselhy¹, Dr, MD, MRCPsych, hamdy.fouad@uaeu.ac.ae

Objective: The abuse of corticosteroids, among Iraqi women, in the Babylon governance and some parts of Iraq was noted during the last two decades. This inspired our group to research into the existence of this problem among Iraqi in Al Hilla city. Our objective of this study was to test the hypothesis that there is an abuse of corticosteroids among this target group for weight gain purposes.

Method: The patients included in the study were recruited from all subjects who had been consecutively visited the 3 primary health centres in Al-Hilla city, Babylon Governorate, Iraq, during a 150 days period (September 2001 to January 2002). A pre-designed questionnaire was used to extract socio-demographic information, and detailed clinical history, mental status examination and drug use histories from patients.

Results: A 120 patients out of 7309 used corticosteroid for weight gain purposes. Female were over represented (80.8%). The average age of the sample was 29 years. Eighty percent felt satisfied with the effect of the drug and 90% were not motivated to stop it. Majority of the patients experienced mood changes but no clear psychiatric syndromes. Doctors were significantly the main source of information about the weight gain effects of corticosteroids.

Conclusions: There are a significant number of patients who routinely misuse dexamethasone. The main original reason for starting it is gaining weight and improves their physical appearance. This issue raises the need for awareness by both general public and medical practitioners of the potential adverse effects of corticosteroids and its devastating consequences.

A NEW QUESTIONNAIRE FOR THE EARLY DETECTION OF ALCOHOL ABUSE AND ADDICTION (AUDIT): GREEK DATA ON RELIABILITY AND VALIDITY

INSTITUTIONS:
1. Athens University Medical School, 2nd Psychiatry Department, Athens, Greece
2. Athens Psychiatric Hospital, Short Term Unit for Alcoholic Addiction Treatment, Athens, Greece
3. General Hospital Sotiria, Psychiatric Department, Athens, Greece

AUTHORS:
1. George I Moussas, Prof, MD, PhD, gmps@vodafone.net
2. Georgia Ntantouti, Dr, MD
3. E Poulis
4. D Mpratis, Mr
5. N Tselebis, Dr
6. A Douzenis, Prof, MD, PhD
7. C Christodoulou, MD, PhD
8. L Lykouras, Prof, MD, FICPM, PhD

Aim
To validate AUDIT in a Greek population.

Material-Method
AUDIT was translated and back translated by two bilingual Greek psychiatrists. 218 individuals took part in the study (128 men and 90 women). 109 (75 M and 34 F) fulfilled the DSM IV criteria for alcohol addiction and presented themselves in alcohol treatment units. The remaining 109 (53 M, 56 F) were healthy controls. Average age of the sample was 40.71 (±11.34). 39.1% were single, 44.6% married, and 14.7% were divorced.

Results
Internal reliability (Cronbach’s a) was 0.80 for the controls and 0.80 for the alcoholics. Controls presented statistically significant lower scores 3.80 (±3.61) (t test p<0.001) from the average score of the alcoholics 26.69 (±8.39). From the alcohol addicted individuals 3% scored 10 or less (the average score plus one standard deviation of the controls). There were 1.8% false positives in the control group. Age was inversely correlated with AUDIT scores only within the alcoholic group (person’s r=-0.05, r=-221).

Conclusions
AUDIT presents a high internal reliability and high validity. Detects 97% of the patients and shows high sensitivity and specificity. Early detection is one of the main issues concerning prevention and treatment, in this respect AUDIT can be of substantial help. AUDIT is a reliable and easy to use instrument for the detection of alcohol problems in vulnerable populations and patients with psychiatric comorbidity.

P-01-084

ANESTHESIOLOGISTS AND DRUG USE: A QUALITATIVE STUDY

INSTITUTIONS
1. Federal University of Sao Paulo, Department of Psychiatry, Sao Paulo, Brazil

AUTHORS
1. Marcelo Niel, DR., MD,MSC, marceloniellmac.com
2. Denise Martin, PHD
3. Dartiu Xavier da Silveira

Objective: The aim of this study is to comprehend drug use among anesthesiologists, focusing on a work-related context.

Method: A qualitative study divided in two principal parts: (1) field observation (2) in-depth interviews: fifteen anesthesiologists participated in this research.

Results: The analysis of the interviews demonstrated, from the empirical data, the context of drug use among anesthesiologists. With the interviews and ethnographic observation, it was possible to describe the context and how the professionals comprehend this behavior.

Discussion: Some paradoxes in the anesthesiologist's routine: the first one was related to the contact with patients and death; the second one was related the control of work rhythm and the search for a specialty with more autonomy. Other subjects were touched, like the negative aspects of the profession as a predisponent to drug abuse, the anesthesiologist's view of use of drugs, the presence of depressive states and the facilitated access to drugs.

Conclusion: This study, despite having found an illustrative description for the quantitative data, looked at the phenomenon in a very specific way. Therefore, it has found the logic inside the anesthesia practice, with the day-by-day contradictions and its coping strategies. It can be assumed that the drug use phenomenon is present on the anesthesiologists' professional horizon; so, dislocating the analysis to the professional practice is the best way to comprehend the several responses to it, since it is not independent from the judgment of society.

Studies show that children diagnosed with Attention Deficit Hyperactivity Disorder (ADHD) maintain the symptoms in adulthood, interfering in the academic, professional, affective and social life. Early diagnosis and appropriate treatment can significantly reduce symptoms. This review is focused on treatment of individuals who present with concomitant ADHD and Substance Use Disorders (SUD), from Medline, Pubmed, Psycinfo, Lilacs and books published in the last 17 years (1990-2007).

INTRODUCTION: This study comes from the interest of professionals of two drug treatment community centers, both located at São Paulo, Brazil, on understanding chemical dependence among women.

OBJECTIVE: The main objective to compare the social-demographic and comorbidity profiles of chemical dependent women.

METHOD: It was a cross-sectional study, based on registered data of the women in treatment between June 1st, 2006 and June 30th, 2007. The data-collecting was done through a social-demographic and diagnosis questionnaire, elaborated and applied by professionals. The studied sample was composed by 130 women.

RESULTS: Comparisons were made from age, instruction, housing, profession, origin, civil status, religion, number of children, diagnosis of dependence, beginning of use, psychiatric diagnosis, psychiatric internments, time of treatment before the abandonment, clinical-surgical diseases, repetitions of diagnosis, clinical tests for hepatitis B and C and for HIV, story of violence, negligence and abandonment in childhood and story of current violence of the patients.

DISCUSSION: some similarities were in the two centers, in terms of age of beginning of treatment, professional status, housing, instruction, civil status, index of unemployment, dependence and spontaneous arriving at treatment. Depression was the most prevalent illness among the psychiatric diagnosis.

CONCLUSION: Through this work, many similarities between the women of the two centers were found, although these services are located in regions with different social-economic profiles.

KEYWORDS: woman; chemical dependence; violence; social stigma; prejudice; treatment of dependents; alcohol; drug

THE COMPREHENSION OF BRAZILIAN HEALTH PROFESSIONALS CONCERNING SPECIALIZED CENTERS FOR DRUG DEPENDENCE TREATMENT

INSTITUTIONS
1. Federal University of Sao Paulo, Department of Psychiatry, Sao Paulo, Brazil

AUTHORS
1. Marcelo Niël1, DR, MD, MSC, marceloniel@mac.com
2. Kamila Helena Prior Carvalho1, DR, MD
3. Reinaldo Antonio Carvalho1

Introduction: The creation of specialized centers for drug dependence treatment is intimately related to psychiatric reform in Brazil. In the eighties a dehospitalization movement was born in Brazil, with a multiprofessional treatment concept. These changes were the “nest” for the creation of specialized centers for drug dependence treatment.

Objective: To comprehend different thought patterns among health professionals concerning the existence of these specialized centers and its relation with the premises of Health Ministry.

Method: This was a qualitative-exploratory study with semi-structured interviews with eleven health professionals.

Results: It was possible to understand the difficulties among health professionals in these specialized centers, such as problems with the government structure and the comprehension about the importance of this type of specialized structures.

CHILDHOOD BULLYING BEHAVIOURS AND SUBSTANCE USE IN LATE ADOLESCENCE

INSTITUTIONS
1. University of Turku, Department of Psychiatry, Turku, Finland
2. University of Turku, Department of Child Psychiatry, Turku, Finland

AUTHORS
1. Sanna Niemelä1, Dr, MD, solnie@utu.fi
2. André Sourander2, Dr, MD, PhD, andsou@utu.fi

Objective: To study the prospective associations between childhood bullying behaviours and substance use in late adolescence among males in a nationwide longitudinal birth cohort study.

Methods: A general population sample of 2946 8-year-old Finnish boys was followed up from age 8 to 18. In 1989, information about bullying and victimization, and childhood psychopathology (Rutter scales and Child Depression Inventory) was collected. At age 18, information about self-reported smoking, drunkenness frequency, use of illicit drugs, and psychopathology (Young Adult Self-Report) was collected from 79% of the boys attending the study in 1989.

Results: After controlling for childhood and late-adolescent psychopathology, family background, and substance use, bullying others frequently predicted illicit drug use (OR=3.0, 95%CI 1.3-6.7). Bullying others occasionally predicted independently for daily smoking (OR=1.7, 95%CI 1.2-2.3). Victimization to bullying at age eight independently predicted daily smoking (OR=1.7, 95%CI 1.02 - 2.7), and lower occurrence of illicit drug use (OR=0.3, 95%CI 0.1-0.8) at age 18.

Conclusions: Among males, childhood victimization is an independent risk factor for smoking, supporting the self-medication hypothesis. Bullying others should be considered as a marker of risk for later substance use. These results further increase our knowledge of long-term consequences of bullying, and highlight the efforts to prevent childhood bullying.
P-01-089

STUDY OF THE M.M.P.I OF ALCOHOLIC PATIENTS

INSTITUTIONS
1. Psychiatric Hospital Of Attiki, Short Term Unit For Alcohol Addiction Treatment, Athens, Greece

AUTHORS
1. Georgia M Ntantouti, Mrs, Md, gmntps@gmail.com
2. Kiki Therapou, Mrs
3. Christos Chombas, Mr
4. Evaggelos Poulis, Mr
5. Georgios Moussas

Objectives
Clinical profile of alcoholic patients as derived from the M.M.P.I subscales.

Method
247 alcoholic patients (194 men and 53 women), completed the M.M.P.I, their demographic details were recorded, as well as type of alcoholism

Results
The average age was 42.2 years ± 6.96, and the years of education 12±3.376. Marital status: 29.1% were single, 36.4% married and 32.8% divorced. Type of alcoholism: 78.5% was type I and 21.5% type II.

M.M.P.I results: highest was the scale 8 (Sc) with an average t-score value 82±19.643, scale 4 (Pd) with an average 76±5.651 and 2 (D) with an average 74 ±6.513. Women presented higher values in the Pd scale in comparison with men (79±5.818 vs 74±5.528, ANOVA F=6,278 p<0.05) and men higher values in the D scale in comparison with women (75±6.335 vs 73±6.331, ANOVA F=15.082 p<0.01).

The age group 20-35 presents higher values in the Pd scale as compared with the age group 46-60 (79±6.269 vs 71±5.812, ANOVA F=4.240 p<0.05) as well as singles and divorced in the same scale as compared with married (76±5.583 and 79±5.774 vs 71±4.905 ANOVA F=4.266 p<0.01). Finally alcoholics of type II present higher values in the Pd scale as compared with the ones of type I ((81±6.237 vs 74±5.405 ANOVA F=7.789 p<0.01)

Conclusions
The scales of Pd, D and Sc is high, even if the last one should be interpreted mainly as an expression of anxiety rather than an expression of pure psychotic characteristics. Women have higher scores in the Pd scale than men and the alcoholics of type II have increased values in the Pd scale, which is expected, based on the clinical characteristics of this type of alcoholism.

YOUNG PEOPLE’S ALCOHOL OUTBREAK

INSTITUTIONS
1. Apsa, Cap. Fed, Buenos Aires, Argentina

AUTHORS
1. Gallego lluesma O.G.II, Octavio, Dr., MD, cppba@yahoo.com

"An uncertain future, the feeling of inner emptiness, the lack of a crucial projects and the absence of important values have been more than a decade inducing the young to pursue pleasure derived from an object rather than a subject" (Miguez H. 2007)

In modern times, men put emphasis on hope, progress and future but in postmodernism the mass media form a new subjectivity and vulnerability. Anywhere, “everything is ok”, immediacy, lack of reflection and spending time with friends were replaced by “the meeting taste” (slogan from a well know beer advertisement), a glass of beer, two...and then drunkenness became a synonym of fun and a challenge of traditional norms of society.

The absence of family and school institutions as germs of society should transmit values and educate under the principle of personal effort in order to achieve improvement and gain satisfaction of the job done. They also should set limits to transgressive behaviour. With this absence, addictions develop as the result of a social conflict unable to prepare young people to use freedom in a responsible way and to aim at their so desired happiness.

Field work: In Argentina, between 2005 and 2006, there were carried out eight hundred surveys to young people between 14 and 17 years old belonging to public and private secondary schools in Capital Federal and Gran Buenos Aires. The result, as it was previously stated, showed that 40 % of young people from both sexes drank every weekend and started with their drinking habit.

Several lines of evidence showed that the endocannabinoid system is involved in vulnerability to development of addiction and other psychiatric disorders. There are two well-characterized cannabinoid receptors, CB1 and CB2. The CB1 but not CB2 receptor might mediate the psychoactive effects of cannabinoids and marijuana use, because the CB1 receptor is highly expressed in the brain and the CB2 receptor is expressed predominantly in immune and hematopoietic cells. However, recent studies demonstrated that the CB2 receptor is also expressed in some region of the brain observed in brain and supposed to be associated with addiction vulnerability as a modulator of the reward system. A previous study showed that the association between the CB2 gene and Japanese alcoholics. Therefore, we investigated the association between the CB2 gene and methamphetamine dependence/psychosis. Subjects were comprised of 223 patients and 221 age- and gender-matched healthy controls. We genotyped a nonsynonymous polymorphism, Q63R, in the CB2 gene. There were no significant differences between controls and patients with methamphetamine dependence/psychosis. In the clinical feature analyses, in respect with age of first use, latency of psychosis, spontaneous relapse of psychotic symptoms, and poly-substance abuse, we found no significant association with the Q63R polymorphisms in the CB2 gene. This study did not support the proposition that the CB2 gene play a major role in methamphetamine dependence liability and/or the development of methamphetamine induced psychosis, at least in a Japanese population.

The psychiatric morbidity —endogenous and exogenous psychoses, neurosis and abnormal personalities, psychosomatic diseases, addictions, sociopathies and so on— is studied mainly on first grade relatives in 6 cases of female patients affected with anorexia nervosa, 2 monozygotic twins; 2 dizygotic twin and 2 cases of anorexia nervosa on non-twin sisters. On both patients and their families, cathaminic study has been made and syndrome-shift or psychiatric polysyndrome coincidences-alterations have been estimated. Finally, results and genetical and clinical findings are discussed in the scope of etiological theory of anorexia nervosa.

The motivation is directed to resolve the following problems: anxiety reduction, depression; diminish a sense of inferiority, revive self-confident, a lifestyle changing, as well as improve a whole life quality. On the analysis basis of abundance interventions to dependence sickness, it's confirmed that motivation is a significant for dependent persons. The motivation was present in 56% of patients, which are included in accidental specimen of 150 patients. Some of the most common individual interventions in aim to accomplish standards-motivations are: motivation for cooperation, motivation for treatment, correcting wrong statements and ideas which are in relation with sickness, motivation in achieving life habits, motivation for companion and realizing the social contacts, motivation for joining a group work. The motivation is a treatment segment that stimulates personal activity of patient and enables their defending from outside and of negative contents that sickness has.

Key words: motivation, standards, norms.

The research is included group of 40 patients, dependents of PAS which are hospitalized in a ward for dependents treating. The first control group of 20 patients, further a usual detoxifying therapy, has been treated by therapy that includes usage of anxioylitics and hypnotics in aim to trim the symptoms of abstinence crisis. The second group, along with detoxifying therapy, daily has been on occupational-recreational therapy, while adjuvant therapy has been included just in case of need. The goal of research: comparative analysis of adjuvant therapy consumption /anxiolytics and hypnotics/, in reference to pointing an importance of occupational-recreational therapy to dependents. The expected result is saving adjuvant pharma-cotherapy and easier abstinence establish in the second dependents group. As parameter of success, in research will be used anxious scale /MMPI/, which is done on the beginning, during, and at the end of a treatment.

Key words: dependent, abstinence, occupational therapy.

ADULT ATTACHMENT STYLE AND ADDICTIVE DISORDERS

INSTITUTIONS
1. Magalhães Lemos Hospital, Psychiatry, Oporto, Portugal

AUTHORS
1. Isabel Santos Rocha1, Ms, MD, mroca@sapo.pt
2. Sandra Carvalho Guimarães1, Dr, MD, saguima@portugalmail.com

Objectives: There are few studies reminding the pattern of adult attachment style and addictive disorders. With this study we propose to clarify this relation.

Methods: This is a prospective study, involving a sample of 18 patients that attend to a centre of addictive disorders. We applied two psychometric scales (Adult attachment scale - EVA), validated to the Portuguese population, and the Brief Symptoms Inventory - BSI). Also a questionnaire with some clinical and socio-demographical data was applied. We compare this data with 18 healthy controls assigned to the study.

Results: The mean age of the group of patients was 35.5 years old (min=21; max =52) and in the controls 33.2 (min=19; max=55); the sex distribution was, respectively, 11:7 and 12:6 (M:F). In concern to the adult attachment style (secure vs. insecure) we found a significative statistical difference between the groups (p<0.001), with major prevalence of insecure attachment style in the group of patients. In this group there was a prevalence of the Fearful - avoidant (38.9%) and Preoccupied (22.2%) Type. The Index of general symptoms (IGS) in the BSI was superior in the group of patients (0.944 vs. 0.632). We found a statistical difference (p<0.01) in Depression and Anxiety items, in the group of patients. The sample will be enlarged to 30 patients.

Conclusion: In this study we find a strong relation between the insecure (Fearful - Avoidant, Preoccupied) Attachment style and addictive behaviour, stating the importance of psychotherapy in this population of patients.

ASSOCIATED FACTORS WITH ILLICIT DRUG USE AMONG COLOMBIAN ADOLESCENT STUDENTS

INSTITUTIONS
1. Universidad Autonoma de Bucaramanga, Grupo de Investigación de Neuropsiquiatria, Bucaramanga, Colombia

AUTHORS
1. German Eduardo Rueda-Jaimes1, Dr., MD, gredu@unab.edu.co
2. Paul Anthony Camacho1, Dr., MD, paulanthony.camacho@gmail.com
3. Andres Mauricio Rangel-Martinez-Villalba1, Dr., MD, andresmauricio.rangel@gmail.com

Background: The abuse of illicit drugs is established during early adolescence. Furthermore, a lot of variables in Colombian adolescents have not been studied yet.

Objective: To establish the prevalence and associated factors of illicit drug use among adolescent students in Bucaramanga, Colombia.

Methods: A random sample of adolescent students completed an anonymous questionnaire asking about illegal and legal substance use, CAGE questionnaire, CES-D Scale, Francis Scale, Rosenberg Self-Esteem Scale, the module for antisocial personality of the questionnaire of the structured clinical interview for DSM-IV axis II diagnosis, and family APGAR. Logistical regression was used to control confounding variables.

Results: 2916 students participated in this research. Mean age was 14.4 years; 51.1% was female. The prevalence of illicit drug use during the last year was 6.48% (95%CI; 5.59-7.38). Illicit drug use in men was associated with antisocial behavior (OR=2.07; 95%CI 1.09-3.92), smoking everyday during the last month (OR=5.24; 95%CI; 2.33-11.82), alcohol dependence pattern (OR=1.56; 95%CI; 1.22-2.01), having a friend who uses illicit drugs (OR=5.76; 95%CI; 2.96-11.21) and having a brother or sister who uses illicit drugs (OR=2.27; 95%CI; 1.14-4.52). In women was associated with antisocial behavior (OR=4.27; 95%CI 2.41-7.57), having a friend who uses illicit drugs (OR=1.31; 95%CI; 1.04-1.66), having a brother or sister who uses illicit drugs (OR=2.43; 95%CI; 1.31-4.61) and smoking everyday during the last month (OR=5.24; 95%CI; 2.33-11.82).

Conclusions: One in 15 adolescent students from Bucaramanga has used illicit drugs during the last year. Women and men showed similar associated factors but statistical different.
P-01-097

VALIDITY AND RELIABILITY OF TWO SILHOUETTE SCALES IN COLOMBIAN ADOLESCENTS

INSTITUTIONS
1. Universidad Autónoma de Bucaramanga, Salud Mental, Bucaramanga, Colombia
2. Universidad Autónoma de Bucaramanga, Epidemiología e investigación, Bucaramanga, Colombia

AUTHORS
1. German Eduardo Rueda-Jaimes¹, Dr., MD, gredu@unab.edu.co
2. Paul Anthony Camacho², Dr., Msc, pancalo@hotmail.com
3. Silvia Milena Florez³, Dr., MD, simiflopy@hotmail.com

Background. The “silhouette scales” are the most useful tools to assess Body-Image Dissatisfaction, however in Latin-America there is no validity tools.

Objective. To determine the validity and reliability of the 13-card scales and Standard Figural Stimuli to evaluate the body.

Methods. A validity study with a probabilistic sample in 189 Colombian student adolescents was designed. The students fill out the 13-card scales and Standard Figural stimuli and after two weeks they fill out these scales again, as well as, the SCOFF questionnaire, the Rosenberg Self-Esteem Scale. The fat body percentage, weight and size were evaluated. Convergent validity was determined through the Spearman coefficient. The test-retest reliability was evaluated through Lin's coefficient.

Results. Mean age was 14.1±1.3 years; 67.2% were female. The correlation of the perceived size assessed through the Standard Figural stimuli with body mass index, weight and fat body percentage was 0.71, 0.55 and 0.46; with the 13-Card scales was 0.60, 0.50, and 0.40 respectively. The Body-Image Dissatisfaction with Standard Figural Stimuli was correlated with the SCOFF questionnaire (0.43) and Rosenberg Self-Esteem Scale (0.26) and with the 13-Card scales the correlation was 0.50 and 0.22, respectively. The test-retest reliability of the perceived and ideal size with the Standard Figural stimuli was 0.85 and 0.78; with the 13-Card scales was 0.93 and 0.9 respectively.

Conclusion. Convergent validity is good for both scales. The reliability of the Standard figural stimuli is good; the reliability of the 13-Card scales is excellent.

VALIDATION AND COMPARISON OF SCREENING TOOLS FOR MENTAL DISORDERS IN SUBSTANCE ABUSERS

INSTITUTIONS
1. Centre for Addiction and Mental Health, Health Systems, Toronto, Canada
2. Whitby Mental Health Centre, Oshawa, Canada
3. Health Canada, Ottawa, Canada

AUTHORS
1. Brian R Rush¹, Dr., PhD, brian_rush@camh.net
2. Saulo Castel², Dr., MD, saulo@rogers.com
3. Bruna Brands³, Dr., PhD, bruna_brands@camh.net
4. Tony Toneatto¹, Dr., PhD, tony_toneatto@camh.net

Aims: Few screening tools for mental disorders have been properly validated in substance abuse clients. They also differ widely in comprehensiveness and administration time. We sought to validate and compare the performance of three screening tools for mental disorders (PDSQ, K10, and GAIN-SS), in a heterogeneous substance abuse treatment population.

Methods: 164 clients were recruited from three large multimodal treatment centres in Ontario Canada (67.1% male; 32.9% female). Clients completed the selected screening tools followed by independent same-day structured clinical interview (SCID) to verify research diagnosis. Breathalyzer, urine screen and self-reported use were used to control for possible effects of intoxication and withdrawal. Performance of each measure against the gold standard SCID was compared using ROC curves.

Results: The sample was heterogeneous in terms of lifetime drug dependence, for example, alcohol 56.1%; cocaine, 55.5%; cannabis 32.9% and opioids 17.7%. The prevalence of depressive disorder was 53.7% and for anxiety disorder 43.2%. For anxiety disorder, ROC's were .787, .701, and .682, for the PDSQ, GAIN-SS and the K10, respectively. The ROC's for depressive disorder were .599, .523, and .622, respectively. For depression, the ROC's were .599, .523, and .622.

Conclusions: All three screening measures fell short of validation data derived from non-treatment populations. The PDSQ performed best for anxiety disorders but no measure was a top performer for depression. Heavy drug use may result in mild symptoms, or sub-threshold groups of symptoms, thus blurring the boundaries across disorders. In other words, as the distinction between cases and non-cases is less clear, the accuracy of any screening tool tends to decrease.

3. Nithikorn - Sorncha3, Mr., MD, dr_nitikorn@hotmail.com
4. Karoon - Hongka1, Miss., -, hkaroon2000@yahoo.com

Objective: This study was to examine the difference of motivation to reduce alcohol consumption in alcohol dependence patient who were treated with MET with and without media.

Methods: This was a randomized controlled trial which 46 alcohol dependent patients were treated with MET at psychiatric out-patient department, Khon Kaen Hospital. They were randomly allocated by computer generated urn randomization to 2 groups; (i) with media group (effect of alcohol to the body by power point presentation initially and 1 week after were presented to them) and (ii) without media as a control group. All subjects were treated by 4 sessions of MET in 12-week period (week 0, 1, 6 and 12). Stages of Change of Readiness and Treatment Eagerness Scale and Drinker Inventory of Consequences were used to measure motivation to reduce drinking and consequence of drinking respectively (Cronbach = 0.82 and 0.88 respectively). Data were analyzed using descriptive statistics, independent t-test and repeated measure ANOVA.

Results: Twenty four participants were completed at the end of the study (13 subjects in media group and 11 subjects in control group). No differences in relation to baseline characteristics between 2 groups were detected. Percent heavy drinking, amount of alcohol and Drinker Inventory of Consequences were significant decreased in both groups. Motivation to reduce alcohol consumption was also similar between these 2 groups.

Conclusion: Media which exhibited the effects of alcohol on human health showed no consequences to the motivation to quit drinking in the alcohol-dependents who treated with MET as the out patients.

3. Sang-Soo Lee1, Mr, MD, easymp@paran.com
4. Beom-Woo Nam1, Mr, MD, PhD
5. Seok Woo Moon1, Mr, MD, PhD

Aims/Objectives: Smoking has been shown to be associated with dyslipidemia that is characterized by an atherogenic lipoprotein phenotype, with increased triglyceride (TG) and low high density lipoprotein cholesterol (HDL) concentrations and a preponderance of low density lipoprotein cholesterol (LDL). We examined changes in lipid profile between before and after smoking cessation in Korean male smokers.

Methods: The urine cotinine levels of all subjects were monitored three times, before cessation, after 1 month, and after 2 months. Blood sampling was withdrawn from the participants twice, at the baseline and after 2 months. At 7:00 a.m. after overnight fast, a sample of blood taken from all subjects to measure levels of HDL, LDL, and TG.

Results: LDL level decreased significantly (p=0.023) after smoking cessation, however change of HDL and TG was not significantly. The level of albumin and total protein were significantly lower after smoking cessation than before.

Conclusion: We hypothesized the smoking cessation would make a higher level of HDL and lowering LDL and TG, but the result was not same as expected. Smoking is the most important preventable risk factor in various disease, so we should take into account the beneficial effects of cigarette smoking cessation in educating smoker to help stop smoking.

Background: This study aimed to investigate the association of alcohol dependence with some candidate genes related to alcohol metabolism and reactions in the central nervous system [aldehyde dehydrogenase 2 (ALDH2), brain derived neurotrophic factor (BDNF), 5-hydroxytriptamine transporter gene linked polymorphic region (5-HTTLPR), Methylenetetrahydrofolate reductase (MTHF)] in older korean men.

Methods: Study subjects consisted of community dwelling 300 men aged 65 or over. They were categorized into 68 subjects with alcohol dependence and 232 controls according to DSM-IV criteria. Genotypic polymorphisms were tested using polymerase chain reaction and restriction fragment length polymorphism. Genotypes were classified into three groups that 5-HTTLPR genotype was to to s/s, s/L, l/l; BDNF to Val/Val, Val/Met, Met/Met; MTHFR to C/C, C/T, T/T; and ALDH2 to 2*1/1, 2*1/2, 2*2/2 respectively. Genotype distribution and allele frequency were compared between the subjects with and without alcohol dependence.

Results: The subjects with alcohol dependence had significantly higher frequencies of ALDH2*1 allele, and BDNF Met/Met genotype and Met allele compared to the controls (all P-value < 0.05), however, there were no significant differences in the genotype distribution and allele frequencies of the 5-HTTLPR and MTHFR genes between the two groups (all P-value > 0.3).

Conclusions: Alcohol dependence was associated with ALDH2*1 and BDNF Met alleles in older Korean men. These results might contribute to understand the pathogenesis of alcohol dependence to some extent.

Because alcohol dependence is a multifactorial condition, involving not only physiological factors, a strategy of biopsychosocial approach is frequently used. A pharmacological manner to support the treatment of alcohol dependence is the administration of disulfiram, a drug that inhibits aldehyde dehydrogenase, which increases acetaldehyde concentration and produces an aversive reaction to alcohol intake. Disulfiram is currently used by oral route, with the inconvenience of the high abandonment of therapy and patient adherence. In this work we evaluated of a new parenteral formulation of disulfiram to support the rehabilitation of alcohol abusers. We proposed that an inclusion complex of disulfiram-cyclodextrin allows obtaining a sustained release of disulfiram to maintain stable therapeutic levels. The patients received 6 months i.m. treatment with the complex (15 mg/kg of disulfiram). The pharmacokinetic-profile was established by measuring disulfiram and its metabolites in blood by means of HPLC/UV. This innovation allowed maintaining stable therapeutic drug levels during one month without pain or injury in the injected area which increased patient adherence to the treatment. From the clinical viewpoint, this formulation, as support to the biopsychosocial treatment of alcohol dependence, represents a new option of therapy employing a multimodal intervention.

Background: This study aimed to investigate the association of alcohol dependence with some candidate genes related to alcohol Metabolism and reactions in the central nervous system [aldehyde dehydrogenase 2 (ALDH2), brain derived neurotrophic factor (BDNF), 5-hydroxytryptamine transporter gene linked polymorphic region (5-HTTLPR), Methylenetetrahydrofolate reductase (MTHFR)] in older Korean men.

Methods: The subjects were categorized into 68 subjects with alcohol dependence and 232 controls according to DSM-IV criteria. Genotypic polymorphisms were tested using polymerase chain reaction and restriction fragment length polymorphism. Genotypes were classified into three groups that 5-HTTLPR genotype was to to s/s, s/L, l/l; BDNF to Val/Val, Val/Met, Met/Met; MTHFR to C/C, C/T, T/T; and ALDH2 to 2*1/1, 2*1/2, 2*2/2 respectively. Genotype distribution and allele frequency were compared between the subjects with and without alcohol dependence.

Results: The subjects with alcohol dependence had significantly higher frequencies of ALDH2*1/1 and ALDH2*1 allele, and BDNF Met/Met genotype and Met allele compared to the controls (all P-value < 0.05), however, there were no significant differences in the genotype distribution and allele frequencies of the 5-HTTLPR and MTHFR genes between the two groups (all P-value > 0.3).

Conclusions: Alcohol dependence was associated with ALDH2*1 and BDNF Met alleles in older Korean men. These results might contribute to understand the pathogenesis of alcohol dependence to some extent.

The objectives of this study are 1) to estimate the rate of cigarette and alcohol use in female adolescents, and 2) to invest the association of substance use, eating pattern, and the related psychopathology. We conducted a survey of 864 girls at one junior high school (n=405) and one high school (n=459) with questionnaires of the general information related to smoking and drinking behaviors, the Three Factor Eating Questionnaire (TFEQ) for eating pattern and the Strengths and Difficulties Questionnaire (SDQ) for psychopathology. In addition, the BMI and the discrepancy of perceived and ideal body image were calculated. The prevalence of cigarette and alcohol use were 35.1% and 11.5%, respectively. Hyperactivity and conduct problems were found in smoking and drinking female adolescents. Smoking girls at high school got a low disinhibition score of TFEQ and high BMI, and showed considerable discrepancy between perceived and ideal body image. Drinking girls at high school got a high score in both disinhibition and hunger patterns and a low score in dietary restraint. For the junior high schoolgirls, the lower disinhibition score is, the higher the risk of smoking and drinking is, but for the high schoolgirls, the lower dietary restraint score is, the higher the risk of drinking is. And, disinhibition/hunger measures and psychopathology are positively correlated. We conclude that substance use in female adolescents is closely associated with externalizing behavioral problems, and eating pattern is mainly related to drinking rather than smoking.

5. Takehiko Okamura¹, Dr, MD, PhD

BACKGROUND: Ministry of Health, Labor and Welfare of Japan estimated that there are almost 810,000 patients with alcohol dependence in Japan. However, it also reported only 51,000 patients received treatment. On the other hand, it is reported that the number of prescriptions of benzodiazepines in Japan is high. We supposed that many alcohol dependent patients with psychiatric symptom have treatment with benzodiazepines without the diagnosis of alcohol dependence. We suspected that most of their psychiatric symptoms are caused by alcohol and the patients need less benzodiazepines when they are abstinent.

OBJECTIVE: To confirm that the patients with alcohol dependence require less benzodiazepines for insomnia and anxiety after hospitalization for detoxification.

METHODS: At Shin-Abuyama hospital, we offer one month treatment program, including detoxification and rehabilitation, for in-patients with alcohol dependence. We reviewed the chart of all 67 female patients who received the treatment for alcohol dependence and discharged from Shin-Abuyama hospital between October 2006 and September 2007. We compared the amount of benzodiazepines they took for insomnia and anxiety, before and after hospitalization.

RESULT: 26 patients (39%) were prescribed some benzodiazepines as hypnotics before admission, and 13 (20%) patients took more than one. When they are discharged, 17 patients (25%) needed benzodiazepines for sleep, only 4(6%) of them took more than one type. 18 patients (27%) took anxiolytics before admission. However, 5 (7%) patients in anxiolytics at discharge.

CONCLUSION: Most of the symptoms alcohol-dependents complaining were relieved after detoxification. The patients did not need as much benzodiazepines as they were drinking.

Aim: To assess and compare the short term treatment outcome among group of smokers and smokeless tobacco (SLT) users.

Method: A prospective, observational study with six months follow-up period using step ladder treatment pattern. Step I- behavioural counseling (BC), StepII- BC with medications, StepIII- BC with Nicotine replacement therapy (NRT), Step IV- BC, NRT and medications. The final step of treatment was decided by use pattern, patient preference and clinical assessment. Total 194 adult smokers and 203 SLT users studied (n= 397).

Results: Of 216 patients on regular follow up (92 smokers and 124 SLT users), Step I had 6 patients (3 in each group), Step II had 5 smokers and 3 SLT users, 18 smokers and 29 SLT users were at step III, 62 smokers and 90 SLT users required step IV. The change rate (reduced consumption and complete abstinence) was 79.7% in smokers as compared to 45.9% in SLT users, with 36.9% smokers and 37% SLT users showing complete abstinence. The change rate at step III in SLT users was 17.9%, with complete abstinence in 7.2% while in smokers it was noted to be 16.35 % and 4.8% respectively. At step IV the change rate for smokers was 59.8%, with abstinence rate of 29.3% and in SLT users it was 55.6% and 27.4% respectively.

Conclusion: No significant difference found in the response pattern to the type of treatment, though the change rate was more in smokers. Both groups required intensive treatment options for better adherence and outcome.

The peripheral-type benzodiazepine receptor (PBR) is a transmembrane spanning protein, pharmacologically, structurally and functionally distinct from the central-type benzodiazepine receptor. PBR is expressed in almost all the peripheral mammalian tissues, including blood cells, as well as within the brain glial cells. A wide spectrum of putative functions has been attributed to PBR, such as steroid biosynthesis, immune responses et al. The present study is the observation of modifications in the binding of [3H]PK11195, a specific PBR ligand, on the membranes of platelets from patients with alcoholism. Using specific radioligand, [3H]PK11195, the kinetic binding parameters of PBR were determined on platelet membranes of 36 adult alcoholic patients and of 19 healthy volunteers. The patients were drug-free at the time of evaluation and blood sampling. Each point represents an individual subject. Bmax and Kd values from controls and analyzed patients were obtained by Scatchard analysis of saturation isotherm. A significant increase in mean platelet PBR density value was observed in the overall sample of alcoholic patients as compared to controls (3398±242 fmol/mg proteins vs 4733±379, P<0.005). In addition, the Kd values, which are in the nanomolar range, were not significantly changed in patients group. Considering the primary mitochondrial localization of PBR, its role in regulating some mitochondrial functions, question of PBR role appears therefore relevant in those neurodegenerative and neuropsychiatric pathologies, where mitochondrial dysfunction has been considered to play a pathogenic role. Our findings may provide new insights into the pathogenesis of alcoholism and form the basis of future studies on function of PBR.

Psychostimulants have been shown to induce extreme changes in aggressive and social interactions: intense and sudden acts of aggression as well as total withdrawal from any social intercourse. The aim of the present study was to assess the effect of 3 different low doses of methamphetamine (MA) on social interaction and locomotion in adult male rats. Test of social interaction (SIT) was used as a test of anxiety in three types of stress environments. Habituation in Open field prior to testing and intensity of lighting were the environmental factors. Thirty minutes prior to SIT animals were or were not injected with MA (0.5; 1.0; 1.5 mg/kg). Animals of the same treatment and weight were assigned to one pair. Each pair was assessed as a unit. Frequency and time spent by social interaction (SII), locomotion and exploratory behavior were examined. Our results showed that acute MA administration decreased time spent by SII in dose-and environment-specific manner, while it did not change the frequency of SII. High doses of MA and stress conditions also increased locomotion in the open field test. Because intensity of SII is often associated with anxiety in rats, our results showing decreased time spent by SII might suggest that MA has anxiogenic effect. On the other hand, no changes in SII frequency dispute this hypothesis. Elevated plus-maze as a test of anxiety will be used in future studies to assess this question.

Introduction: Craving for cocaine seems to play an important role in the continued use of and dependence on the substance. Aims: to describe characteristics of the craving phenomenon in a sample of cocaine users and to identify those that could predict the appearance of the phenomenon. Method: 205 cocaine users attending an outpatient clinic were interviewed to assess patterns of drug consumption and characteristics of craving for the drug. Findings: Subjects were mostly young (24.8 + 12.8 years) and male (86.2%). One hundred and two subjects (49.8 %) were addicted to cocaine and the remainders (50.2 %) were non-addicted occasional cocaine users. The majority of subjects (60.5%) reported having had craving episodes during the previous week. Frequency of cocaine use during the previous month correlated with the number of reported craving fits (r = 0.425; p < 0.001) and with the duration of the craving fits (r = 0.351; p < 0.001). Users of crack reported more craving episodes than did the users of snorted cocaine (p < 0.001) and the frequency of craving fits was inversely proportional to the duration of abstinence from the drug (r = -0.405; p< 0.001). Conclusion: Both the method of drug consumption and the abstinence period elapsed since previous drug intake were identified as predictive parameters of craving.

Recent use of psychoactive substances among 456 medical students throughout the six grades was surveyed by way of a self-report questionnaire using World Health Organisation criteria. Considering gender differences, among male medical students, the most frequently used substances were alcohol (80.5 %), cannabis (25.3 %), solvents (25.2 %), and tobacco (25.2 %), whereas among female students the most frequently used drugs were alcohol (72.6 %), tobacco (14.6 %), solvents (10.5 %), and tranquillisers (7.5 %). Among medical students, after alcohol and tobacco, cannabis and solvents were the most frequently used psychoactive substances. Factors associated with the recent use of cannabis and solvents were established by logistic regression. Living with parents or a companion appeared as a protective factor for the use of cannabis. However, being male and regularly participating the Athletic Department activities showed as risk factors for the use of both cannabis and solvents. Examining patterns of substance consumption throughout the medical course showed that switch from illegal to legal drugs were observed only among female students, whereas male students tended to alternate cannabis and solvents throughout college years. Interventions aiming to influence patterns of drug consumption among medical students must consider both gender differences and evolutional patterns of substance use throughout medical course.

PREDICTIVE FACTORS OF COMPUTER ADDICTION IN A GREEK SAMPLE OF ADOLESCENT STUDENTS

INSTITUTIONS
1. University of Thessaly, Medical School, Larissa, Greece
2. University of Thessaly, Psychiatric clinic, Larissa, Greece

AUTHORS
1. Kostas E Siomos1, Mr., MD, ksiomos@med.uth.gr
2. Penelope Avagianou2, Dr., PhD, penavagia@yahoo.gr
3. O D Mouzas1, Dr., PhD
4. N V Angelopoulos1, Professor, PhD

Objective: The objective of the present study was to create a predictive factor model regarding computer addiction in Greek adolescent students.

Method: The sample is constituted of 2200 Greek students. A representative sample selected randomly. All participants were given to complete: Computer addiction test (CAT), a 20-item internet addiction test, where the word internet was replaced by the word computer, a questionnaire regarding demographic characteristics, the Athens Insomnia Scale (AIS), the Symptom Checklist SCL-90-R, and the Yang Diagnostic Questionnaire (YDQ), by Young K.S, a test which is based on the guidelines regarding internet addiction. All tests were translated into Greek.

Results: Data was analyzed using stepwise multiple regression analysis, for finding out which factors have a predictive value for computer addiction, in Greek adolescent students. A six-factor model emerged, which can explain 77% of the variance of the independent variable (CAT score). The internet addiction score, hours per week of computer use, number of years of computer use and the sex of the user, seem to be predictive factors for 59% of the cases with computer addiction.

Conclusions: Computer addiction is strongly associated with internet addiction. Many hours of use, frequent use and increased number of years of computer use seem to be the most important predictive factors of computer addiction. Insomnia symptoms and male sex have also a predictive value. Mental health professionals should bare in mind the above factors when dealing with cases of computer addiction, since this six-factor model can predict six out of ten cases.

BDNF-GENE POLYMORPHISMS AND EATING DISORDERS SYMPTOMS IN BELARUSIAN SAMPLE (PRELIMINARY RESULTS)

INSTITUTIONS
1. Belarusian State Medical University, Psychiatry & Medical Psychology, Minsk, Belarus
2. Institute of Genetics and Cytology, Belarus National Academy of Sciences, Minsk, Belarus

AUTHORS
1. Oleg A. Skugarevsky¹, Dr., MD, PhD, skugarevsky@tut.by
2. Nina G. Danilenko², Mrs., PhD, cytoplasmic@mail.ru

Objective: to determine the interrelation between single nucleotide polymorphisms (-270 C/t and G196a (Val66Met)) of brain-derived neurotrophic factor gene and peculiarities of eating disorders symptoms (anorexia nervosa (AN), bulimia nervosa (BN), DSM-IV) at the initial examination.

Methods: Reference to the frequency determination of two SNPs of BDNF gene in positions -C270T and G196A in Belarusian population, we used case-control study. In control group (age- and sex-matched, n=30) clinically healthy persons with current disordered eating phenomenon (observed or assumed) had been detected and excluded from subsequent investigations. The main group includes 38 in-patient women suffering from eating disorders (AN, n=22; BN, n=16). The following characteristics were under assessment: BMI and its fluctuation within 5 years prior to assessment, current motivation for weight change, the Eating Attitude Test (EAT-26), The eating disorder examination (EDE), Body image satisfaction scale (BISS), Symptom Check List-90-Revised (SCL-90-R), Personal Orientation Inventory (POI) (adopted Russian version). For both SNP genotyping we used PCR-REFP analysis.

Results: The presence of BDNF-gene polymorphisms (mainly G196A) revealed statistically significant correlations with clinical features of eating disorders (severity of bulimic symptoms, self-control over eating, body image dissatisfaction, somatisation, obsessive-compulsive and phobic anxiety phenomena, as well as behavior flexibility and self-expression spontaneity).

Conclusions: Reference to the study results obtained, the consequences of BDNF-gene expression due to SNP of -C270T and G196A is hypothetically suggested to correspond to the eating disorder symptoms peculiarities.

WHO’S AT THE RISK OF BECOMING A PATHOLOGICAL GAMBLER? A NEURO-VISUALIZATION APPROACH TO THE PROBLEM

INSTITUTIONS
1. Scientific Center for Care and Rehabilitation Phoenix, Rostov-on-Don, Russian Federation

AUTHORS
1. Alexander O. Bukhanovsky¹, Prof., MD, PhD, bux@jeo.ru
2. Victor A. Soldatkin¹, Dr., MD, PhD, sva-rostov@mail.ru

Objectives. To study the morpho-cerebral predisposition towards pathological gambling (PG) through neuro-visualization (MRI) of those patients suffering from this disorder.

Methods. Visual and quantitative analysis of the cerebrum tomo-grams of 75 PG patients. Tomography was carried out by the Philips Gyroscan Intera (1.0 T) device. The compare (intact) group representatives had the same age and sex parameters.

Results. MRI finds could be systematized as follows:
1. Signs of dysontogenesis. 29.3% of the patients had cysts: of the speculum (6; 8.0%), retrocerebellar (5; 6.7%), of the pineal area (3; 4.0%), of the arachnoid (3; 4.0%); sinus cysts in 5 (6.7%) patients. 19 (25.3%) patients showed other signs of dysontogenesis, predominantly of the brain vascular system.
2. The signs of reduced (against the control group) volume of the frontal brain areas were:
A) high frequency of expanded subarachnoid chinks of the frontal region; this manifested itself much lesser in other brain areas;
B) the frontal horns index was by 19.8% higher than in the control group. In respect that the width of the frontal horns equaled the control value, one might assume some frontal lobe decrease;
C) expanded frontal areas of the Sylvian fissure is an indirect indication of peculiarities of the frontotemporal area.

Conclusion. We consider the above neuro-visual peculiarities as manifestations of the perinatal brain injury and/or a dysontogenic consequence. These are in our opinion an anatomic component of PG predisposition. Organic brain ‘inadequacy’ allows lesser stress-resistance and greater imprinting-accessibility, which raises the risk of non-chemical dependence progression.

A new approach is suggested to examine and cure smokers. It was clinically tested and verified on more than 2000 smokers with smoking period 15-25 years and established that tobacco addiction syndrome has 3 main components: somato-vegetative, neurotic and mental.

Three forms of smoking dependence also were clinically described: mental, dissociative and psychosomatic. Each of them has its own combination and representational level of addiction syndrome components.

With the usage of special testing scale a psychiatrist can create different therapeutic ways to cure different forms of tobacco dependence. The result of this approach is more than 70% patients with high therapeutic effect compared to 30-40% with other approaches. Tobacco free period is longer, too.

Definite personality and hereditary-constitutional way of visual one/and verbal recollection of memories and ideas of smoking link with each form of smoking dependency. For example, people with mental form of tobacco dependency are more likely to have schizoid personality features and visual way of recollection memories. The addiction syndrome is mostly mental.

Dissociative form is preferable for people with neurotic one depressive features. The way to recollect memories of smoking is most commonly combined: visual/verbal or verbal/visual. Addiction syndrome has somato-vegetative component of high level and other components of lower levels.

People with psychosomatic form of tobacco dependence are definitely to have at least some epileptoid character features and to recollect smoking mostly by using verbal memories. The addiction syndrome is represented by all the 3 components with high level of them.

5. Agnieszka Grzywa-Bilkiewicz⁴, Mrs., PhD

Aims: The aim of the paper was to analyze stress burden, to assess the level of anxiety and depression and some health factors among addicts, (ACoAs) and controls.

Methods: There were 129 subjects studied [30 alcoholics (AA), 42 drug addicts (N), 26 ACoAs and 31 non-addicts controls (K)]. 70 subjects were females (54,3%) and 59 males (45,7%). The average subjects age was 29,3 (SD 8,07). The burden of stress was measured by means of Readjustment Scale and ETI. To assess emotional state of subject HADS and STAI as well as CECS were used. SOC, SWLS and LOT-R were used in the study as measures to determine coping abilities.

Results: The differences of the burden of traumatic events in childhood (ETI) between the groups were statistically significant (p<0.005) in range of following subscales: ETI I (general trauma), ETI II (physical abuse) and ETI III (emotional abuse) and was the higher result was observed in group of ACoAs (454,2 point in total). The level of stressful events with last 12 months was statistically different as well (p<0,02) and the higher among AAs. The level of anxiety (STAI, HADS A) and depression (HADS D) was significantly lower in controls than in other studied groups. LOT-R revealed no differences between groups. Satisfaction with life was higher in ACoAs than in AAs (p<0,05). Health resources (SOC) were significantly higher in controls in comparison to others.

Conclusions: Alcoholics, drug-addicts and ACoAs are characterized by significantly heavier burden of stress, higher emotional distress and lower health resources than controls.

4. Anna Kurzeja3, Mrs.
5. Agnieszka Grzywa-Bilkiewicz4, Mrs., PhD

Aims: The aim of the paper was to determine psychosocial differences between female alcoholics and female drug-addicts and ACoAs and healthy females.

Methods: There were 70 females in the study included [13 alcoholics (AAs), 9 drug-addicts (N), 17 ACoAs and 31 healthy controls (K)]. The average subjects age was 20.3 (SD 8.5).

The burden of stress was measured by means of Readjustment Scale for current stressors and Early Trauma Inventory for childhood stressors. To assess emotional state of subjects Hospital Anxiety and Depression Scale, State and Trait Anxiety Inventory as well as Courtauld Emotional Control Scale were used. SOC, SWLS, LOT-R were used in the study as measures of healthy resources.

Results: Female alcoholics and drug-addicts were significantly worse educated (p<0.05), their job career was poorer and more frequently have a family history of psychiatric disorders. In the childhood drug-addict females and ACoAs were significantly more frequently exposed to abuse measured by ETI. The level of stressful situations within last 12 months was the highest in the group of alcoholics. The level of anxiety and depression was significantly higher in AA and N groups. The rate of negative emotions control, especially regarding control anger, was the highest in the group of alcoholics. Sense of coherence as the measure of health resources was significantly lowest in ACoAs.

Conclusion: Females having problems with addictions require individually tailored therapies considering psychosocial differences.

ALCOHOL ABUSE AND JEALOUS DELUSIONS DUE TO WILSON’S DISEASE

INSTITUTIONS
1. Aristotle University of Thessaloniki, 3rd Psychiatric Department, Thessaloniki, Greece

AUTHORS
1. Styliani Spyridi1, spyrridesstella@yahoo.com
2. Ioannis Diakogiannis1, diakoi@med.auth.gr
3. Apostolos Iacovides1
4. Georgios Kaprinis1, kaprinis@med.auth.gr

Aim and background: Wilson’s disease or hepatolenticular degeneration is a rare autosomal recessive disorder of copper metabolism that results in failure of biliary excretion of copper and its deposition in brain, liver, kidneys and the cornea. Due to the copper deposits in the brain, neurological and psychiatric symptoms may appear. Psychiatric symptoms can occur in approximately 50% in the early phase of the disease and commonly are found in patients presenting neurological signs. The psychiatric manifestations may vary from mood disorders, behavioral and personality disorders to cognitive impairment, while psychiatric symptoms are rarely reported. Delusions in Wilson’s disease are uncommon and only few reports are found in the literature, mainly in neurologically impaired patients with persecutory delusions. The aim of this report is to present an unusual case of Wilson’s disease presenting with alcohol abuse and jealous delusions.

Case summary: A 34-year-old male patient, without any previous psychiatric or alcohol abuse history, presented with jealous delusions and alcohol abuse when he discontinued his treatment for Wilson’s disease. Although the patient had no previous symptoms or neurological signs, he was receiving treatment for Wilson’s disease for 3 years, after being diagnosed with the disease during family precautionary examination, since his brother developed symptomatic Wilson’s disease. The patient started treatment with Risperidone and Trientine Dihydrochloride and after 3 months follow-up the psychiatric manifestations were controlled sufficiently.

Conclusions: Although Wilson’s disease is rarely associated with alcohol abuse and jealous delusions, this disease should be taken into account in the differential diagnosis of these psychiatric manifestations.

Aim and background: Heroin abuse, particularly vapor inhalation, has been associated with a rare form of leukoencephalopathy, characterized by symmetric hyperintensity on T2-weighted and FLAIR MR sequences, affecting the cerebellum and the posterior limb of the internal capsule, with sparing of the anterior limb. This radiological image is crucial for the diagnosis, especially due to the indefinite history of abusers that can often be complicated by hypoxia, toluene toxicity etc. Acute toxic leukoencephalopathy due to heroin inhalation can be reversible while delayed toxic leukoencephalopathy may have poor prognosis. The aim of this report is to illustrate the clinical picture and the neuroimaging findings of a case of toxic leukoencephalopathy caused by heroin intravenous overdose.

Case summary: A 31-year-old HIV-seronegative male heroin addict was hospitalized in our department, due to psychotic symptoms and cognitive impairment. 33 days earlier, after heroin intravenous overdose, the patient was found comatose and was admitted to the intensive care unit. No specific findings were revealed from the routine hematological and biochemical tests, while EEG was normal and MRI was typical of spongiform leukoencephalopathy. Neurological examination did not demonstrate pathological findings, but gait disturbance and instability. Extensive neuropsychological examination revealed global cognitive impairment. Clinical improvement occurred under treatment with alopiprazol 10 mg, biperiden 4 mg and naltrexone 50 mg daily.

Conclusion: Spongiform encephalopathy is a rare form of toxic encephalopathy of white matter, mostly associated with inhalation of pre-heated heroin. Although other modes of heroin intake are not related often to this entity, it is suggested to be considered after intravenous heroin injection.

4. Dragoljub Jovanovic1, Mr., stasi@beotel.net
5. Sonja Pejic1, Mrs., stasi@beotel.net

Objectives: Ecstasy (MDMA), the substance 3,4-methylenedioxy-methamphetamine is an amphetamine derivate. The effects of ecstasy can be described as those of a hallucinogenic amphetamine, combinatorily amphetamine with that of LSD. It is available as a tablet, capsule, powder and liquid. Recently, MDMA has become the recreational favourite drug for many young people. Ecstasy toxicity is unpredictable and tremendous abuse potential.

Methods: We exposed the 25-male patient who treated in Special Hospital of Addictions, Department of Multiple Drug Users in period of October to November 2007 and diagnosed according the ICD-10 like mental and behavioral disorders due to multiple drug use. MDMA urine detection sample (positive), also available medical data about defined acute myocardial infarctions (ECG, biochemical and pathologic characteristics, blood sampling for serum markers, clinical features like chest pain and discomfort, etc.), review actual related articles and studies.

Results: The exposed patient diagnosed by ICD-X like mental and behavioral disorders due to multiple drug use (MDMA, alcohol, sedatives) three years ago. Periodically he abuse alcohol and excessively consumption drinking, 6 months before the actual treatment he used 4 tablets of MDMA and develop conditions like acute myocardial infarctions and treated at coronary care unit. His conditions verified by ICD-X. It was the first time for appear such clinical features.

Conclusions: There is a poor research studies and report about the cardiac toxicity by MDMA, especially induced acute myocardial infarctions. Besides, we want to show up the link between this condition and abuse MDMA.

Aims: Technology, computers and the Internet, seem to be at best easily overused and at worst, addictive. Studies of general computer users suggest that some children may experience psychological problems such as social isolation, depression, loneliness, and time management related to their computer use and failure at school. We investigated the risk factors leading to computer addiction.

Methods: This study examined computer behavior of 450 teenagers, aged between 15 to 18 years old. All the students come from Iasi, Romania. The teenagers answered to a questionnaire comprising 34 questions related to computer activities. The questions addressed self-appreciation behavior, cognition, opinions, and the attitude toward social life of the respondents. These were aimed at highlighting: 1. Frequency of computer use by the teenagers; 2. Teenager's opinion of computer use; 3. Association between computer addiction and another mental illness. 4. The interference computer addiction with social and academic performance.

Results: There is little doubt that children can at times become captivated by the intrinsic opportunities provided by the computer technology and the Internet. The results show that the parents don't recognize computer addiction. We present a descriptive analysis of the aspects of computer addiction by teenagers and the various comorbidities.

Conclusion: Moreover, teenagers with computer addiction had comorbidities like depression, anxiety, drug or alcohol addiction.

THE NEGATIVE IMPACT OF ALCOHOLISM OVER THE HUMAN BEHAVIOR

INSTITUTIONS
1. Alba University, Alba Iulia, Romania

AUTHORS
1. Liviu Stoica¹, Dr, PhD, livius_dr@yahoo.com

Integrally spread around the world the alcoholism knows falling periods but also periods of development. In close addiction with the social and economic conditions of each society, alcoholism makes as an important element in the waste of material and human resources, through damaging goods or high social costs by maintaining millions of individuals with disabilities and problems due to alcohol abuse in hospitals and shelters. These things are just some of the negative aspects of this phenomenon because the absence of a set of general, medical, social, relational and psychological unitary criteria necessary in the communication of the diagnosis makes the exact determination of the alcoholism impossible. In this paper we try to explain that the alcoholism diagnosis does not say much about the way, cause and degree of this type of behaviour. The particularly conditions of each person with alcoholism diagnosis must be identified and analysed to make a correlation with all the possibilities of intervention.

4. Paulo Sarti, Mr., MD  
5. Carlos Pinent, Doctor, PhD

**Objective:** The purpose of this study was to examine the demographic characteristics, drug use and justice involvement in a patients that seeking treatment for substance use disorders.

**Methods:** Fifty drug-addicted men participated of this study. All the subjects were psychiatric outpatients. They completed several questionnaires. The measures were a self-report and included a self-report measure of alcohol and others drugs use. The sociodemographic instrument had questions upon the justice involvement.

**SPSS 11.5 was used by the statistical analyses.** Descriptive statistics include frequency, percents and means.

**Results:** Overall the patients had 12-month abuse or dependence some drug. Aged 18 to 63 years; low income; 46.9% were married. Sixty per cent had some member on family with alcohol or other substance abused. The most patients (39.4%) are used various psychoactive substances; 12.1% are used alcohol only. The drugs more used were: alcohol (69.7%); tobacco (63.8%); cocaine (48.5%); marijuana (45.5%); crack (39.4%). Around 30% of the sample related that was arrested due to drugs use. These related several hospitalizations and large drugs use among their family members.

**Conclusions:** Alcohol or illicit drugs abuse is associated with domestic violence, poor treatment adherence, neuropsychological impairment, arrests, criminal recidivism, unemployment and high psychiatric co-morbidities prevalence. Thus are serious personal and public health problems. Associations of alcohol dependence with others a substance use disorder is frequently and suggests common causal factors like genetic or psychological. The data can be indicative of a more severe illness in the patients that have to do with justice involvement.

**TRAUMATIC EVENTS, POSTTRAUMATIC STRESS SYMPTOMS, DEPRESSIVE SYMPTOMS AMONG DRUG USERS IN TREATMENT – PRELIMINARY DATA**

**INSTITUTIONS**  
1. Pontifícia Universidade Católica do RGS, Graduated Program, Porto Alegre, Brazil  
2. Instituto de Pesquisa e Prevenção em Álcool e Outras Dependências, Research, Porto Alegre, Brazil

**AUTHORS**  
1. Gilda Pulcherio, Mrs., MD  
2. Marlene N. Strey, Doctor, PhD  
3. Paulo Sarti, Mr., MD  
4. Daniel P. Fenserseifer, Mr.  
5. Carlos Pinent, Doctor, PhD

**Objective:** The present study is investigating traumatic events, posttraumatic stress disorder symptoms (PTSD), depressive symptoms among male with substance dependence.

**Methods:** All the subjects (n=50) were psychiatric outpatients of the Institute of Prevention and Research on Alcohol and others Dependence, Porto Alegre, Brazil. They completed the following instruments: Specific Traumatic Events Scale, Davidson Trauma Scale, Beck Depression Inventory, sociodemographic characteristics. The measures were a self-report. SPSS 11.5 was used by the statistical analyses. For the correlation between PTSD severity symptoms and severity depressive symptoms, it were applied the Chi-Square Test and Fisher Exact test.

**Results:** 96.4% of drug-addicted in treatment experienced to at least 1 traumatic event during their life. The most common event, 68.7% was the sudden and unexpected death of a close friend or relative. Depressive symptoms were related about 70%. Forty percent punctuated a total score of 40 or more in the Davidson Trauma Scale which suggests PTSD. Positive correlation between PTSD severity symptoms and severity depressive symptoms (p<0.005) were found.

**Conclusions:** These data show the importance of investigating trauma and depression in drug users, for their high co-occurrence. There is agreeing with the literature although the small sample. Due to the vulnerability of these patients to the exposure traumatic events, the trauma evaluation in the patients’ history is essentially important as a preventive factor of the chronic Posttraumatic Stress Disorder and treatment of the comorbid disorders. The depressive symptoms could be result of trauma and PTSD or due to depression disorder, independent of PTSD.

SPECIFICATIONS OF ABSTINENCE SYNDROME OF OPIUM DRUG ADDICTS WITH SCHIZOPHRENIA

INSTITUTIONS
1. Kazakh National Medical University, Kazakhstan

AUTHORS
1. A. S. Subkhanberdina
2. I. Bespalova

The aim is to study clinical peculiarities of opium narcotic abuse when it develops together with schizophrenia. The patients - 78 persons with schizophrenia (F 20.0; F 20.6; F 21.0) and opium narcotic drug abuse - demonstrated a schizophrenic process starting from the age of 14-25 years. The stage of drug abuse referred to the age of 18-25 years, and was characterized by ataractic motivation and by the drug abuse alone. The stage of trying multitude of narcotics lasted for up to 3 years. The 1st stage of drug addiction was marked by structurally incomplete pathological drug addiction, the growth of tolerance towards opiate of no more than 2-3 times, the length from two to five months. At the second stage there was a hedonistic use of opiates, lack of transformation of the clinical picture of sharp intoxication by the drugs retaining euphoria in the structure, and incomplete structure of abstinence syndrome. Severity of abstinence syndrome of schizophrenia patients was determined by its clinical structure. When abstinence syndrome was of medium and high severity, its clinical picture was dominated by somatic and neural disorders, and when the syndrome was light then marked by psychopathological disorders. The structure of abstinence syndrome varied depending on the form of combined psychological pathology. The paranoid schizophrenia was characterized by the light form of abstinence syndrome with psychopathological disorders. In simple form of schizophrenia and in patients with schizotypical disorder the abstinence syndrome of medium and heavy severity with somatic and vegetative disorders prevailed over psychopathological ones.

7. M. Arrojo-Romero

Objectives: Impulse control disorders have been frequently reported in patients with bulimia nervosa. However there are few reports measuring impulsivity traits in clinical samples. The aim of this pilot study is to determine the impulsivity traits in a sample of bulimic outpatients from an Eating Disorders Unit.

Methods: Impulsivity was assessed with the Spanish adaptation of the Barratt Impulsivity Scale (BIS-11) in 27 bulimic women and 38 healthy controls. Both groups were matched by age and educational background.

Results: Bulimic patients show higher mean scores in global (53.59 vs. 39.39; p < 0.01), cognitive (16.85 vs. 12.13; p < 0.01) and motor impulsivity (18.78 vs. 11.32; p < 0.01). There were no significant differences in non-planned impulsivity.

Conclusions: Bulimic patients were more impulsive in cognitive and motor areas than healthy controls in our sample. These findings could help us understand the neurobiological basis of bulimia nervosa and improve its pharmacological treatment.

Objective: The purpose of this qualitative study is to determine the main factors involved in alcoholics anonymous (AA) adherence after a period of hospitalization according to patients' information.

Method: This cohort involved 300 patients with alcohol dependence committed to 3 hospitals in Porto Alegre, Brazil. They were interviewed again in their homes after 6 months. The SCID-I and a questionnaire focusing on patient relationship with the AA groups were used. The responses obtained through the questionnaire were independently evaluated by two researchers.

Results: All patients fulfill criteria for alcohol dependence according to the SCID-I. AA adherence was below 20%. The main factors reported by patients as reasons for non adherence to AA were: relapse, lack of identification with the method, lack of need, and lack of credibility. The factors reported by patients as reasons for adherence were: identification with the method and a way to avoid relapse.

Conclusion: Although AA is considered an effective intervention for alcoholism (1), its adherence rate was excessively low (2, 3). The identification of these non-adherence factors could help health professionals in referring certain patients with alcohol dependence to therapeutic interventions other than AA.

9. Lucas Spanemberg1, Dr., MD, lspanemberg@yahoo.com.br
10. Dartiu Xavier Da Silveira1, Dr., PhD, dartiu@terra.com.br

Objective: This study was designed to ascertain the main factors associated with abstinence or relapse among alcoholics at a 6-month follow-up after a period of hospitalization.

Method: Three hundred alcoholic patients were interviewed at hospitalization and again 3 and 6 months thereafter, in Porto Alegre, Brazil. Assessment included the SCID-I, a questionnaire focusing on patient relationship with AA groups, and questions about participation in psychotherapy. A logistic regression analysis was performed to determine predictive variables for relapse or abstinence 6 months after discharge.

Results: Previous treatment for alcohol dependence (OR=3.65; CI:1.77-7.05) and being single (OR=2.39; CI:1.06-5.42) proved to be associated with relapse; whereas adherence to AA (OR=0.31; CI:0.15-0.66), presence of a co-morbid depressive disorder (OR=0.46; CI:0.23-0.92), and probably adherence to psychotherapy (OR=0.52; CI:0.26-1.04) could be associated with abstinence.

Conclusion: These findings reinforce the importance of psychotherapy and AA groups for alcoholics to remain abstinent for longer (1). The greater adherence to treatment observed among depressive alcohol dependents can be explained by the fact that this is a co-morbid condition that acts as a protective factor against relapse (2, 3).

ANXIOUS DEPRESSIVE DISORDERS IN ALCOHOLISM

INSTITUTIONS
1. Military Emergency Clinical Hospital “St Odobleja”, Psychiatry, Craiova, Romania

AUTHORS
1. Alexandru Tiugan1, Mr, MD, PhD, tiuganalexandru@yahoo.com
2. Claudia Radut1, Ms, MD

BACKGROUND: The neuro-biological underlayer of the anxious and depressive disorders that is the anatomic amygdale circuit with the recompense paths (ventral segment and nuclei accumbens) are intercorrelated with the alcohol use. The serotonergic and noreadrenergic dysfunctions as well as the dopaminergic deficit (especially in the recompense path) together with the disfunctions in the GABAergic and GLUTAMAT-ergic lines are found in both psychopathologic board[1].

OBJECTIVE AND METHOD: A retrospective 5-year study was carried out (2002-2007) to highlight the incidence of anxious depressive comorbidity in the addiction disorder. - 140 male patients, aged between 19 and 65 years, fulfilling the DSM IV R criteria for the ‘addiction disorder’ diagnosis.

RESULT: Only 75% of the studied patients showed anxious depressive comorbidity: out of them 15% had it from the first admittance for addiction disorder. For the rest of the patients, the anxious depressive symptomatology was apparent after at least two withdrawal episodes.

CONCLUSIONS: The anxious depressive pathology is developed from the very beginning of the addiction disorders, especially for youngsters. A relapse of alcohol abuse can be induced by an anxious depressive disorder, the patients using alcohol and anxiolitic and antidepressant. Administration of the anxiolitic and antidepressant treatment together with the orthotiming one can improve the prognosis for the addiction disorder through the decrease in relapses, maintaining a prolonged abstinence.

Key words: alcoholism, anxiety, depression, comorbidity

HEPATITIS C AS A MOTIVE OF ABSTINENCE TO DEPENDENTS OF PAS

INSTITUTIONS
1. Special psychiatric hospital Dobrota, Kotor, Serbia and Montenegro

AUTHORS
1. Aleksandar B Tomcuk, Dr.
2. Marina M Roganovic, Dr.
3. Nada I Matkovic, Ms.

The ward for drug addiction treatment, in Montenegro, is opened in 2005 as a part of a ward for alcoholism in the Special psychiatric hospital in Dobrota. At the beginning of sickness, motivation for drug addiction treatment almost doesn't exist. It usual appears with first complications appearance. The dependent is usual coming on a treatment because of family member, possibility for losing a job, healthy problems or court measurements pronounce. The presence of positive and adequate motivations for treatment is rare. Positive means conscious desire and decision for treatment, while adequate, behind that, includes conscious knowledge why patient wants a treatment and what will get with it. During 2007, at the ward are treated 32 heroin dependents which all have hepatitis C. This is a control group and we are compared it with another group of 32 patients, also dependents of heroin, which don't have Hepatitis C. The goal of research is establishing motivation during a treatment and readiness for longer abstinence. Result of research: patients with hepatitis C are represented more adequate motivation, which is proved with: better collaboration with team of therapists, respected rules of family habits, active joining in occupational and work therapy, longer hospitalization - without self-will leaving from the ward, smaller amount of hospitalizations, smaller tendency of aggressive breakdowns.

Key words: abstinence, dependent, hepatitis, motivation.

PSYCHOCULTURAL MEANINGS OF DIETARY HABITS FOR PATIENTS WITH METABOLIC SYNDROME IN A UNIVERSITY OUTPATIENT SERVICE IN BRAZIL: A QUALITATIVE STUDY

INSTITUTIONS
1. State University of Campinas (UNICAMP), Department of Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas, Brazil

AUTHORS
1. Carla Maria Vieira, Mrs., MD, carlmari@fcm.unicamp.br
2. Egberto Ribeiro Turato, Dr., PhD, erturato@uol.com.br

Objective: Knowing the Metabolic Syndrome (MS) carriers manifest often eating behaviour disorders as well as a poor long-term adherence to diets, the authors' aim was to discuss psychocultural meanings of foods and diets usually proposed for the MS patients in clinical treatment. It was hypothesized that the symbolic meanings attributed to the phenomena involved in the dietary habits organize personal ways of seeing life, especially the sense relations of the individuals with food.

Method: Qualitative. Sample was closed when composed by eight subjects, according to data saturation technique. Patients have replied to semidirected interviews with open-ended questions and the set of speeches was submitted to content analysis technique. For the discussion section, it was utilized psychodynamic theoretical framework usually applied to health field teaching.

Results: From collected narratives, it was identified distressing life experiences relative to both food privation and certain eating compulsion. Meanings on a definitive solution in obesity cases were attributed to a possible the bariatric surgery. Some psychological defense mechanisms have been suspected: isolation, negation and rationalization associates to dietary habits.

Conclusion: Determined psychological suffering and low self-esteem have been related to dietary habits, disclosing as impeditive for the self-care - a structuring element for both the quality of life promotion and the reduction of risk factors for the MS patients.

3. Vladimír Novotný, Mr., prof. MUDr. CSc.

Objective: To explore the prevalence of psychoactive substance use in medical students and to compare the current results with our previous research.

Methods: 636 medical students were included in the cross-sectional study. All respondents filled in a questionnaire concerning their use of psychoactive substances. Obtained data were compared with 2 previous waves of our (methodologically identical) research in 1997 (N = 214) and 2002 (N = 230).

Results: In the current study, the most frequent regularly used psychoactive substance was caffeine (49.8% of all respondents), followed by alcohol (12.7%) and tobacco (12.6%). 36.6% of respondents have at least one experience with any illicit psychoactive substance and the most common specific illicit drug repeatedly or regularly used was marijuana (11.7% of respondents). When comparing the 3 research waves, the prevalence of any contacts with drugs is increasing through the years; however the percent of regular users is decreasing in most of the substances, which is discussed later in the paper.

Conclusions: We have found a high prevalence of psychoactive substance use in medical students repeatedly in the three subsequent waves of our research. The spectrum of the most common used drugs remains similar, but the prevalence rates change through years.

3. Deborah Deas, MD, deasd@musc.edu
4. Gregory E Gilbert, MSPH, gilbertg@musc.edu

Objective: Contingency management (CM) is a behavioral intervention that has good evidence for substance use disorders. Recent evidence suggests that CM may reduce smoking behavior among adolescents. This study seeks to explore the effect of CM intervention and study retention and smoking cessation outcome in adolescents participating in a medication trial.

Methods: In an ongoing study of bupropion SR and a CM intervention (escalating reinforcement schedule) for smoking cessation in adolescents, 30 participants have been randomized to CM-only and 30 have been randomized to placebo-only. Retention and biologically verified (CO, cotinine) point-prevalence abstinence rates were examined.

Results: Point prevalence abstinence was higher in CM group as compared to placebo group (p<0.05). There was no significant difference in retention between groups.

Conclusion: Preliminary results indicate that among adolescent smokers, CM may improve smoking cessation and may potentially improve retention. With additional data available, further results will be presented at the meeting.

5. Christos Siotis¹, Mr., info@agiaaikaterini.gr

The preventive treatment of emergency situations and complications caused by chronic alcoholism presents psychiatrists and physicians with a great challenge. Delirium tremens is a potentially fatal form of alcohol withdrawal that usually occurs in patients with heavy and chronic alcohol abuse. The most common symptoms include: seizures, delusions, hallucinations (micropsia), reduced consciousness level, tachycardia, incoherent speech, disturbed psychomotor activity, increased activity of the autonomous nervous system, hyperthermia, dehydration and electrolyte imbalances. The mortality rate varies between 5% and 15% in patients under treatment and rises to 35% when untreated.

Our research took place in a private psychiatric clinic between August 2005 and January 2008. We focused on the effectiveness of a certain pharmacological combination administered to a sample of 20 patients in an attempt to control the alcohol withdrawal syndrome. The sample profile is the following: average age: 43 years, average years of alcohol abuse with previous hospital admissions for alcohol treatment where they developed major alcohol withdrawal symptoms: 12 years. The pharmacological combination comprised 30mg-60mg Chlordiazepoxide hydrochloride, 300mg-500mg triapride hydrochloride, 300mg-500mg hydroxyzine hydrochloride, 576mg Clometiazol, 600mg-1200mg Oxcarbazepine and B1+B2+B12 complex daily. Additionally, our sample received antidepressants and cardiovascular drugs.

None of our sample patients developed any delirium tremens symptoms. The average duration of the drug combination administration was 11 days followed by a gradually decreasing dose until the maintenance dosage was reached.

When compared to other suggested drug treatments applied to alcohol withdrawal this particular drug combination proved to be highly effective in delirium tremens prevention.

2. Snezana Z Alcaz¹, Dr., MD, s.alcaz@gmail.com
3. Ivan D Dimitrijevic², Dr., PhD, i.dimitrijevic@yahoo.com

OBJECTIVE
The substance cannabis and 3,4-methyldioxymethamphetamine (MDMA) is a popular recreational stimulant commonly referred to as club drugs. They produce maladaptive behavioral or psychological changes. Last evidence indicates increasing route for MDMA abuse in new generation. The aim of this study is to evaluate the specific groups of patients and to make the distinction between there gender rate and beginning substance abuse.

METHODS
The retrospective study includes patients treated in Special Hospital on Addictions in Belgrade diagnosed by any set of criteria during the period of last 15 years. Investigation included frequency of drug abuse cannabis, MDMA, heroin, which compare with age and duration of addiction period.

RESULTS
Total of 440 patients were separated to four different groups: main ages 40, 30, 20 and 18 year. At baseline, of the all participants, 82% had used heroin and 64.3% reported that they had injected drugs. Significant positive correlation was found between youngest patients and there first contact (14, 5 year old) with club drugs and frequency of heroin abuse. In a contrarily, in older gender (40 and 30) we found later consummation of cannabis 19,2 and 23,5 year old for MDMA. Also we notice an earlier begging for heroin abuse 16,6 year old for older groups.

CONCLUSION
Our data suggest that distribution of cannabis and ecstasy use in adolescents spread. These results indicate that chronic and frequent drug use may lead to distinct patterns of cognitive impairment in youngest patients and may be getaway drugs for latter heroin abuse.

THE AIM: The investigation was at Syrgery Clinics, in the treatment of eating disorders that refers to the increasing number of patients with bulimia-anorectic symptoms and the problem of overeating as well as the repercussions that these diseases give in psychological, corporal and social plan, not only for the individual, but also for the family and wider social environment. Concurrently, the authors notice a connection between eating disorders, actualization et re-actualization of the symptomatology and surgical intervention like a trigger factor.

MATERIALS AND METHODS: The questioned population is consisted of 36 individuals in total, of which an eating disorder was diagnosed and we can divide them in two subgroups: 5 with anorexia, other 10 with bulimia and the 21 have eating disorder in relation to overeating, accompanied by psychological difficulties i.e. obesity. By the methods used the following: MMPI - 201, PIE, 18 PF- Katel, Scales for Assessment of Obsession, Compulsiveness and Tendency for Schizophrenia. EDI Garner et al. 1983, ECQ Merhabian 1987, FILE, Hamilton, McCubbin, Patterson and Wilson 1983 and Non-standardized Structured Clinical Interview 13 items (trigger factors).

CONCLUSIONS: In the conclusions the author states multicausality of etiopathogenic mechanisms regarding eating disorders: the individual vulnerability of personality, the dysfunctional family and social relations. The author recommends a model of intervention with preventive strategies intended for the population with disfunctionalities in the behavior related to the nutrition, taking into consideration the premise “Health improvement means fight for mental health, opposite the traditional fight against the disease.”

OBJECTIVES: Substance dependency is a deviation that in many years exposed the human kind mainly youth, to the risk situation. In the recent years, young people are the main victims of this phenomenon (1). Regarding to character of our society that youth are majority of population and because this group is targeted in preventive programs of substances (2), so this research was done to describe the experiences of youth with substance dependency about causes of substance use.

METHODS: This is a qualitative- phenomenological study. Participants in this study were 12 youth with substance dependency with range of 18 to 30 years old that was selected with purposive sampling method. Data were collected with in-depth interview and analysis was done via Colaizzi method.

RESULTS: Three main concepts were derived from this study that each of these themes has any subthemes. These are including Personal factors, Family factors and Social factors.

Conclusion: The findings showed that people underlined of different factors such as personal, family and social factors refer to the consumption of opioid and finally depend to this substance. Regarding to findings of present study, in the first level of prevention, three approaches of individual centered, family centered and community centered suggested.

THE USE OF APPETITE SUPPRESSANTS AMONG HEALTH SCIENCE UNDERGRADUATE STUDENTS IN SOUTHERN BRAZIL

INSTITUTIONS
1. University of Caxias do Sul, Biomedical Sciences, Caxias do SUL, Brazil

AUTHORS
1. Carlos Zubaran¹, Prof., MD, PhD, zubaran_jr@yahoo.com

OBJECTIVE: Investigate use of appetite suppressants in Southern Brazil.

METHODS: Survey conducted via a 24-question questionnaire previously validated in Brazil, which was used to investigate a sample of 300 participants from different health science courses in the University of Caxias do Sul (UCS), Brazil.

RESULTS: Men and women were respectively 24.7% and 75.3% of the sample. Enrollment in academic courses was as follows: Biology (8%); Physical Education (25%); Nursing (16%), Pharmacy (14,66%), Physiotherapy (14%), Medicine (8,33%) and Nutrition (14%). Lifetime use of anorexigens was reported by 14.3 % of volunteers. Lifetime use of “Anfepramone” or “Fenproporex” occurred in 4,66% of the sample. The use of appetite suppressants was more common in Nursing (4%) and Nutrition (3,66%). The majority of anorexigen users were women (88,88%). An ANOVA demonstrated that anorexigen use varied significantly according to different academic courses. Furthermore, 28,88% of the volunteers revealed a self-administration modality, whereas 13,32% informed drug use recommended by someone. Finally, 57,77% of the sample used anorexigens due to medical prescription and 24,44% reported a medical consultation during the previous six months. Adverse consequences of drug use were common and from 10% to 20% of volunteers suspended drug intake due to adverse reactions.

CONCLUSION: The use of appetite suppressants is significant in the sample investigated. Women appear to be at higher risk for unsupervised use of appetite suppressants. Adverse reactions to these substances are common. Further studies at community level are needed in order to establish the magnitude of this phenomenon.

ELECTROCONVULSIVE THERAPY PROTOCOL FOR AN ACUTE PSYCHIATRIC UNIT

INSTITUTIONS
1. Centro Hospitalario Benito Menini, Acute Unit of Psychiatry, Valladolid, Spain

AUTHORS
1. Jose A Aguado, Dr., jaaguadom@gmail.com, 2. Olga M Segurado, Dr., osegurado@gmail.com

Objectives
Development of a protocolized procedure of electroconvulsive therapy (ECT) adapted to our hospital.

Method
Review and update the knowledge of ECT, complemented with the recommendations of the manufacturer of the Thymatron ® ECT machine. Conduct training on the ECT device and other necessary systems. Conducting mock application of ECT to improve coordination and sequencing of therapy.

Results
We propose the following protocol, whose headings are:
- Overview and Definitions
- Indications and Contraindications
- Side Effects
- Site and Staff
- Pre-ECT evaluation
- Treatment procedure of ECT

- Post-ECT evaluation
- Documentation and Record Sheet

We also assessed the satisfaction of the staff in a simple questionnaire and collected a list of problems that had to be dealt with.

Conclusions
1. ECT treatment still has a role in the Acute Psychiatric Units.
2. A protocolized and adapted procedure is imperative before implementing ECT treatment.
3. Staff level of satisfaction with our ECT protocol was moderate and more practical training was demanded.
4. Main problems were of an economic nature by requiring general anaesthesia, which increases the cost very much.

THE IMPLICATION OF OXIDATIVE STRESS IN A RAT MODEL OF PARKINSON’S DISEASE

INSTITUTIONS
1. Alexandru Ioan Cuza University, of Molecular and Experimental Biology, Iasi, Romania
2. Gr. T. Popa University, Iasi, Romania

AUTHORS
1. Ciobica Alin, Mr., PhD Student, alinmimi@yahoo.com, 2. Hritcu Lucian, Mr. 3. Artenie Vlad, Mr. 4. Padurariu Manuela

INTRODUCTION
The administration of 6-hydroxydopamine (6-OHDA) into the brain of the rat produces a well-established model of Parkinson’s Disease. It seems that 6-OHDA induces oxidative stress which can lead to the induction of apoptosis and cellular loss. The effects of 6-OHDA are age-dependent as there is a greater effect seen in aged animals compared with young animals, particularly with lower doses of 6-OHDA.

OBJECTIVES
The purpose of the present study was to determine the development of oxidative stress that is generated in a substantia nigra (SN) and ventral tegmental area (VTA) 6-OHDA lesion model of PD through assessing the antioxidant enzymes activities in the temporal and frontal lobes homogenates.

MATERIAL and METHODS
Male Wistar aged rats, 22-23 month-old were used for all experiments.

6-OHDA lesions: SN lesion; VTA lesion.

Biochemical estimations: determination of superoxid dismutase (SOD), glutathione peroxidase (GPX) and malondialdehyde (MDA) activities.

RESULTS
Lesioning of substantia nigra and ventral tegmental area with a low dose of 6-OHDA induced significant reduction in SOD, GPX specific activities and increase of MDA concentration in the temporal lobe rather than in the frontal lobe homogenates, comparative with sham-operated control group. Also, the role of the substantia nigra is more prominent than that of the ventral tegmental area.

CONCLUSION
Our results support that oxidative stress plays a role in the damage produced by substantia nigra and ventral tegmental area injection of 6-OHDA, and that indices of oxidative stress could potentially be important markers for evaluating therapeutic strategies and their effects on 6-OHDA-induced dopaminergic neurotoxicity.

“PSYCHOTHERAPEUTIC BENEFITS OF THE EXERCISES” A REVIEW OF LITERATURE

INSTITUTIONS
1. Masterskill College of Nursing and Health Sciences, Allied Health Sciences, Selangor, Malaysia

AUTHORS
1. Tarun Khanderao Amalnerkar¹, Mr., B.Pt., rxtarun@rediffmail.com

Aims: Psychiatric symptoms like depression, anxiety and obsessive-compulsive disorders are quite common. Several physiotherapy interventions are being used & this review is an attempt to enlighten the efficacy of physiotherapy interventions in treatment of the depressed immune system, psycho morbidity & which are being used clinically.

Methodology: A systematic review was performed by studying various relevant documentations collected from the COCHRANE library, PUBMED, and PEDRO databases. Both physiology and psychology are interrelated and interdependent. As asthma and blood pressure can be easily triggered by anxiety and stress as symptoms can be altered and moderated well with exercise. Regular exercises like jogging, slow running, pace walking, weight bearing, low impact aerobics, and muscular strengthening have been found beneficial in many a studies. Improvements mostly is caused by slow, rhythmic, aerobic exercises, using of large muscle groups with low & moderate intensity. In addition affects on limbic system & life style modification gives feeling of psychological well being.

Result: It relaxes, calms down and unruffled patients by reducing muscle spasm, stress, anxiety & regularizes blood pressure, alveolar functioning, peripheral circulation, thereby improves psychological and physiological functions.

Conclusion: Various literature, studies, and reviews strongly revels the impact of exercises in treating psychiatric disorders. Since ancient era exercises are being used successfully as a therapeutic adjunct. However this concept needs more detailed and evidence based researches, in future proper protocols and techniques with specific intensity & duration can be made.

Freud did not initially encourage psychoanalysts to analyse the elderly. Aging was often used as a contraindication for psychoanalysis. During the last five decades there have been significant advances in psychoanalytic thinking and research. Psychoanalytic authors have been deepening their knowledge about this period of life.

From this study we observed the viability of the treatment, that it depends a great deal in overcoming prejudices in relation to aging. Working through counter transferecial feelings aroused by the patient must be considered.

4. Lianna Gustafson¹, Mrs.
5. Ana Lúcia Severo Rodrigues¹, Mrs., PhD
6. Roberto Andreatini¹, Dr, PhD, randreatini@ufpr.br

Aims
Protein kinase C (PKC) may be an important cellular target for mood stabilizers (lithium and valproate) [1] and tamoxifen, another PKC inhibitor, showed antimanic effect [2]. However, the antiestrogenic effect of tamoxifen can also contribute to its antimanic effect. Thus, the present study investigated the effect of PKC inhibitors tamoxifen and chelerythrine and the antiestrogenic drug medroxyprogesterone (Mpa) in amphetamine-induced hyperlocomotion in mice, an animal model of mania.

Methods
Adult male mice were randomly allocated in the following groups: vehicle + saline; vehicle + amphetamine; lithium/or chelerythrine/or Mpa + saline; lithium/or chelerythrine/or Mpa + amphetamine. Fifteen min after drug administration (lithium or Mpa, s.c/ or chelerythrine, i.c.v.) animals received amphetamine (3.0 mg/kg, i.p.) and, 20 min later, were tested in the automated activity chamber; the number of beam interruptions was measured during 20 min.

Results
Amphetamine increased locomotor activity in vehicle-treated groups. Lithium carbonate (100 and 150 mg/kg, ip), tamoxifen (1.0 mg/kg, ip), and chelerythrine (1 mg/site, icv) completely blocked the amphetamine-induced hyperlocomotion. The intermediate medroxyprogesterone dose (3.0 mg/kg, ip) partially reduced the amphetamine-induced hyperlocomotion, whereas lower (1.0 mg/g) and higher (6.0 mg/kg) Mpa doses had no effect. These effects were seen without any drug-induced change in the basal activity (drug + saline).

Conclusions
Thus, the present results indicated a major role for PKC inhibition in the antimanic-like effect of tamoxifen.

REHAB: A CROSS-VALIDATION STUDY

INSTITUTIONS
1. Psychiatric Hospital of Petra, Olympus, Katerini, Greece

AUTHORS
1. Georgios D Giaglis¹, Dr, MD, PhD, giaglis@med.auth.gr
2. Barbara Michailidou¹, Dr, MD, MSc, barbaradocthess@hotmail.com
3. Georgios F Angelidis¹, Dr, MD, PhD, info@kepsykat.gr

Objective: Hall and Baker’s REHAB is a well-known instrument for the assessment of long-stay patients. This study attempts to evaluate the reliability of its use for chronic psychiatric patients of a Psychiatric Hospital, whose long-stay wards underwent a transformation to community-based psychiatric facilities.

Material and methods: 18 rater-pairs assessed 71 patients before and 10 different rater-pairs assessed 53 patients after the patients’ relocation to hostels and sheltered apartments. The raters were not formally trained but completed the REHAB scale by the use of a structured interview conducted by one of the investigators. For the Deviant Behaviour part of the REHAB, Cohen’s weighted kappa was calculated. For the General Behaviour part Spearman’s rho and a single-measure one-way analysis of variance intraclass correlation coefficient [ICCI(1,1)] were calculated.

Results: For the total of the General Behaviour part, Spearman’s rho was found to be 0.860 before and 0.871 after the hospital’s transformation. The rho for the 5 subscales ranged from 0.665 to 0.830 (median 0.781) before and from 0.784 to 0.904 (median 0.822) after. ICC(1,1) analysis gave similar results. For the Deviant Behaviour part, Cohen’s weighted kappa ranged from 0.633 to 0.811 (median 0.713) before and from 0.656 to 0.936 (median 0.827) after the patients’ relocation. All statistics were significant at the 0.01 level.

Conclusions: These results indicate a very high level of inter-rater reliability of the REHAB scale. It seems to be equally reliable for assessing psychiatric patients in long-stay psychiatric wards as well as after their relocation to community-based psychiatric facilities.
EVALUATION OF THERAPEUTIC INTERVENTION WITH SCHIZOPHRENIA AND SCHIZOAFFECTIVE PATIENTS IN A DAY AREA

INSTITUTIONS

4. António Gomes, Dr., MD

AIMS: To evaluate the benefits of a rehabilitation programme in the Day Area of Centro Hospitalar Psiquiátrico de Lisboa with Schizophrenic and Schizoaffective patients in terms of psychopathology and social functioning.

MATERIAL AND METHODS: We studied 27 out-patients diagnosed with Schizophrenia and Schizoaffective Disorder according to the DSM-IV TR classification, divided in two samples. One group (N=14) participated in the rehabilitation programme and the other one did not participate in any other therapeutic programme. All the patients were taking atypical antipsychotics. Both groups were interviewed, at first and at third month of the study, with the Positive and Negative Syndrome Scale (PANNS) to evaluate the psychopathology and the Multnomah Community Ability Scale to evaluate social functioning.

RESULTS: From the analysed results we verified that the patients who participated in the therapeutic Day Area programme had relevant benefits in the social functioning, but not in psychopathology.

CONCLUSION: The advantages in terms of social functioning verified in the sample submitted to the rehabilitation programme in the Day Area demonstrated that this type of intervention can be useful in the treatment of Schizophrenia to achieve rehabilitation and socio-occupational integration.

QUALITY OF LIFE AND SOCIAL FUNCTIONING IN PATIENTS WITH SCHIZOPHRENIA TREATED WITH OLANZAPINE

4. Slavica Hadzi-Angelkova
5. Ana Filipce

Introduction: Our objective is to present the impact of olanzapine treatment on quality of life and social functioning in patients with schizophrenic symptoms.

Materials and methods: The study sample consisted of 45 out-patients who met ICD-X criteria for schizophrenia, schizoaffective or schizotypal disorder. The instruments used for rating were the following: Brief Psychiatric Rating Scale (BPRS), Positive and Negative Symptoms Scale (PANSS), Schizophrenia Quality of Life Scale (SQLS) and Social Functioning Scale (SFS). The instruments were administered at baseline, after 3 and 6 months.

Results: The 30-item SQLS showed improvement in the items that refer to motivation and energy; symptoms and side-effects as well as psychosocial items. The SFS showed significant improvement in social relationships and interpersonal communication.

Conclusion: Out-patients with schizophrenic symptoms treated with olanzapine have improvement in their quality of life and social functioning.

CHANGES OF MEDICATION USAGE IN INPATIENTS OF MAJOR DEPRESSIVE DISORDER: ONE UNIVERSITY HOSPITAL BETWEEN YEAR 2001 AND 2006

INSTITUTIONS
1. Department of Psychiatry, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

AUTHORS
1. Won-Myong Bahk
2. Ho-Jun Seo
3. Young-Eun Jung
4. Jeong-Ho Chae
5. Tae-Youn Jun

Objectives: The goal of this study was to examine and compare the trend of prescription patterns for major depressive disorder at a university hospital between year 2001 and 2006.

Methods: We evaluated the medication usage of inpatients with major depressive disorder in 2001 and 2006, including antidepressants used as first choice, switching, and combination, and various augmentation agents. And we evaluated the time to switching and combination of antidepressant in 2001 and 2006.

Results: The antidepressants used as first line drug were SSRI's (49.3%), mirtazapine (24.0%), and TCA (4.8%) in 2001, and SSRI's (50.0%), mirtazapine (24.7%), and venlafaxine (19.0%) in 2006, in frequency order. The antidepressants used as switching drug were TCA (33.3%), mirtazapine (25.0%), and nefazodone (16.7%) in 2001, and SSRI's (33.3%), mirtazapine (33.3%), and venlafaxine (19.0%) in 2006. As combination treatment, SSRI's and TCA combination was used mostly by far in 2001 (87.5%), but in 2006, various combination were used including SSRI's and mirtazapine, SSRI's and TCA, mirtazapine and venlafaxine. The time to combination in 2001 and 2006 year were not different significantly, but the time to switching was significantly shorter in 2006 than in 2001. The use of atypical antipsychotics as augmentation agent decreased and the use of atypical antipsychotics increased significantly in 2006.

Conclusion: The results of the present study suggested that there were lots of change in prescription patterns for major depressive disorder between 2001 and 2006.

WEIGHT CHANGE DURING THE ACUTE TREATMENT PERIODS OF MAJOR DEPRESSIVE DISORDER IN PATIENTS ATYPICAL ANTIPSYCHOTICS USED AS AN AUGMENTED METHOD.

INSTITUTIONS
1. Department of Psychiatry, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

AUTHORS
1. Won-Myong Bahk
2. Ho-Jun Seo
3. Young-Eun Jung
4. Jeong-Ho Chae
5. Tae-Youn Jun

Objectives: In current study, we evaluate the weight change of depressive patients who admitted in a closed-ward at a university hospital and compare the weight change and other clinical variables between patients with or without antipsychotics augmentation.

Methods: Patients were included who admitted to the psychiatric inpatient unit for treatment of major depressive disorder and treated with antidepressant only (non-AAP group) or antidepressant augmented with atypical antipsychotic (AAP group) Body weight was measured on weekly basis and we calculated the maximum weight change during the admission. To evaluate substantial weight gain (SWG) of subjects, we assessed the patients who weighted more than 5 kg during the admission or 7% of their initial body weight.

Results: The mean weight gain of APP group (N=72) was 3.07±1.84 kg and that of non-AAP group (N=103) was 1.66±1.88 kg. When controlling the difference of some variables, there was significant difference between the two groups (F=13.943, P<0.001). As for BMI over 25, there was also no significant difference (F=0.014, P=0.557). But when assessed with the criteria of SWG, 20 subjects of AAP group (27.8%) and 13 subjects of non-AAP group (12.6%) met this criteria, and there was significant difference between the two groups (F= 6.362, P=0.018).

Conclusion: The results of the present study suggested that significant weight gain develops in depressive patients who treated with atypical antipsychotics, though it is used as augmented methods with relatively small dose.

AUTHORS
1. Usha Barahmand¹, Dr., PhD, usha.barahmand@gmail.com
2. Malahat Amani¹, Ms., MA, malahat_amani@yahoo.com

Aim: The purpose of the present study was to compare the short term response of symptom dimensions of schizophrenia to treatment with the atypical antipsychotic drug olanzapine and typical antipsychotic drugs. Method: The study sample comprised 86 patients diagnosed with schizophrenia. Olanzapine was prescribed to 53 patients and 33 received typical antipsychotic drugs. Baseline measures of positive and negative symptoms, extrapyramidal symptoms and body weight were compared with assessments made every week for four consecutive weeks and once again at the end of the twelfth week. Results: Findings reveal that all symptom dimensions, positive and negative symptoms as well as the five factors of thought disturbance, paranoid belligerence, depression, anergia and activation symptoms improved with olanzapine and the improvement noted was superior to that observed with typical antipsychotics. Paranoid ideation and positive symptoms were the first to show improvement, while depression and anergia showed the least improvement. Furthermore, slight but significant weight gains and increase in extrapyramidal symptoms were observed at the fourth week of treatment. Conclusions: Overall, although olanzapine appears to have mild side effects, its clinical efficacy is superior to conventional drugs.

Aims: Previous studies demonstrated predictive value of a reduction of prefrontal theta quantitative EEG cordance for fluoxetine and venlafaxine treated, non-resistant outpatients and for resistant patients, which were treated by various antidepressant interventions. We have now examined whether decrease of prefrontal cordance value after 1 week of bupropion treatment predicts clinical response to bupropion in non-responders to previous antidepressants. Methods: We analyzed 12 inpatients, who finished 4-week treatment with bupropion. EEG data were monitored at baseline and after 1 week of treatment. QEEG cordance was computed at 3 frontal electrodes in theta frequency band. Depressive symptoms were assessed using Montgomery-Åsberg Depression Rating Scale (MADRS). Results: All six remitters (achieving both a final MADRS ≤12 and reduction of MADRS ≥50%) and only 2 of 6 non-remitters decreased prefrontal QEEG cordance value after the first week of treatment. The decrease of prefrontal cordance after week 1 in remitters was significant (p=0.03) and there was no change in non-responders. Positive and negative predictive value of cordance reduction for remission was 0.75 and 1.0, respectively.

Conclusion: Preliminary results suggest that QEEG cordance may be a promising tool in the early prediction of the response to bupropion.

4. A. Simon Pickard
5. Nadine Berry
6. Christopher Bell

Introduction: The clinical benefits of pharmacotherapy for the treatment of insomnia have been studied extensively. In this analysis, the cost effectiveness (CE) of eszopiclone for the treatment of primary insomnia (PI) was assessed in the US.

Methods: A model using data from a 6-month, clinical trial (n=824), combined with data from a claims database and published literature was used to assess the quality-adjusted life years (QALY) gained and costs associated with eszopiclone versus placebo in adults with PI. Quality-of-life data were collected using the SF-36; preference-based utility scores were derived using a published algorithm. To model medical and absenteeism costs, patients were classified as remitted (Insomnia Severity Index [ISI] ≤7) or not remitted (ISI >7) from insomnia. Presenteeism costs (lost productivity at work) were based on responses to the Work Limitation Questionnaire. Differences in QALYs and costs from baseline were calculated and CE ratios derived. Uncertainty surrounding the CE ratio was addressed via various univariate and probabilistic sensitivity analyses.

Results: Eszopiclone use resulted in a net gain of 0.0137 QALYs at a net cost of $67 for the 6-month utilization period. The incremental increase in cost associated with eszopiclone was slightly less than $5,000 per QALY gained. Excluding absenteeism and presenteeism costs, the CE ratio was ~$33,000 per QALY gained, which is below the generally accepted CE threshold of $50,000. Sensitivity analyses indicate that the results are robust.

Conclusion: Eszopiclone is cost effective, especially when lost productivity costs are included, for the treatment of chronic PI in adults.

MENTAL ILLNESS: AN AUTOMATIC, LEARNED AND STYLIZED STIMULUS-RESPONSE

INSTITUTIONS
1. Centro de Investigación, Difusión y Promoción de la libertad interior (Cipli), Bahamas

AUTHORS
1. Olivo Blanco

OBJECTIVE: Demonstrate that ‘Mental Illness’ is a phenomenon initiated at home, reinforced in society and stylized internally.

METHOD: Planned introspection, and meticulous evolutionary record of all those internal conflicts unleashed after tireless search of the I, during 30 years.

RESULTS: Paternal impositions, taking implicit social aims, are stimuli that wait, of child, a response; initially they do not work in an automatic way (due to gravitational Natural Inertia of organism tending to be interrelated with the Universe), but as punishment and recompense are imposing on him, time between stimulus-response will be diminishing until reaching the automatization. Reinforced and rewarded such a process, the individual, will be suitable to generate unthinking answers before any stimulus foreign to his essence. Given these conditions any impulse, image or idea arisen in mind unconsciously it turns into stimulus, to which, man, will not be able to escape, undo or obviate having to exercise necessarily an immediate response, according to needs of social rules, avoiding this way non-adaptation or interior conflict: Conditional Inertia.

CONCLUSIONS: The dynamic mind-body, in ‘Mental Illness’, is a reply of the interrelationship father-child but stylized, in which, to less time between stimulus-response the worst it will be the forecast.

Aim: The goal of this paper is to demonstrate the importance of group psychotherapy in the rehabilitation of war victims with psychological consequences.

Method: 15 patients, who experienced war related psychological traumas were included in this research, all of them suffering from chronic consequences of trauma. Initial testing was done before beginning of group psychotherapy with following instrument: Multidimensional Instrument for assessment of psychological symptoms Brief Symptom Inventory BSI-53. The group psychotherapy lasted three months. Sessions were organized weekly and lasted for one and half hours. Group was lead by two co-therapists. Working technique was supportive-expressive psychotherapy. After three months of therapy they were retested with BSI-53 Questionnaires.

Results: After three months treatment of the group psychotherapy on BSI-53 Questionnaire there is reduction in all psychopathological symptoms, on the statistical significance p<0,05.

Conclusions: Group psychotherapy has shown efficiency in treatment of chronic psychological consequences of patients with war related trauma. Group experience helped patients to establish the better social relationships with others.

CLOZAPINE AND CARDIOTOXICITY: ECHOCARDIOGRAPHY FINDINGS

INSTITUTIONS
1. Barwon Health, Australia
2. University of Melbourne, Australia

AUTHORS
1. Joanna Fitzsimons¹,²
2. Thomas Callaly¹
3. Seetal Dodd¹,²
4. Michael Berk¹,²

Background
Despite clozapines efficacy profile, there is a risk of life threatening adverse effects associated with clozapine treatment. Both myocarditis and dilated cardiomyopathy have been reported in association with clozapine treatment. The current study aims reports echocardiographic changes in clozapine treated individuals followed up prospectively.

Methods
Transthoracic echocardiograms were done prior to commencing clozapine treatment (Time 1) and again after 6 to 12 months (Time 2), as part of routine cardiac monitoring. In addition, psychiatric and medication history were documented. Full white blood count, troponin I and creatinine kinase results were performed.

Results
A decrease in left ventricular shortening, a measure of ventricular contractility, was seen between Time 1 (pre clozapine) and Time 2. Further analyses will be presented.

Conclusion
Clozapine causes a progressive reduction in left ventricular contractility that is of potential clinical significance. The risk benefit ratio of clozapine treatment needs to be clarified in the light of these findings. Safety monitoring of clozapine may need to include serial echocardiography to detect at-risk individuals.

Objectives: Electroconvulsive therapy (ECT) remains the most effective treatment for severe depression. EEG variables such as ictal amplitude and post ictal suppression have been shown to predict clinical outcome. We wanted to evaluate the predictive value of EEG characteristics, specifically ictal amplitude, post ictal suppression, degree of synchronisation, and seizure duration, on the therapeutic outcome.

Methods: We retrospectively assessed the EEG records of 34 consecutively treated patients who received ECT for an episode of major depressive or schizoaffective (depressive) disorder. Severity of depression was rated with the 24-items version of the Hamilton Depression Rating scale (HAM-D-24). Ratings were conducted before, and in weekly intervals during the course of ECT. Remission was defined as ≤10 points on the HAM-D-24. EEG records were rated manually by two researchers blinded to the clinical outcome, and a third researcher arbitrated on discrepant rating.

Results: The only variable that reached significance was the quality of post-ictal suppression, in line with previous research. However the correlation was weak and had low predictive value. The main factor affecting EEG quality was age (poorer with older age). Duration of seizure had no predictive value.

Conclusions: EEG characteristics have some predictive value for the clinical outcome in ECT delivery and clinicians should aim at achieving EEGs with high amplitude, good synchronisation and, most importantly, a clear post-ictal suppression. However, the predictive value is modest and depends on other factors, such as age, medication and the number of previous ECT sessions. Patients can improve even with poor EEGs.

BIOCHEMICAL - CLINICAL COMPARISON OF DIFFERENT RISPERIDONE TYPES ADMINISTRATION

INSTITUTIONS
1. School of Medicine Rosario, Psychiatry, Rosario, Argentina

AUTHORS
1. Daniel Dachesky¹, Dr., MD, danieldachesky@unr.net.ar

After the selection of sixty patients with clinical diagnostic of schizophrenia (DSM IV) they were divided in two groups of thirty patients that received during ninety days equivalent doses of oral risperidone and intramuscular long acting risperidone. During the test determinations of blood levels were made, complete haematology function and differential count; glucose, insulin, estradiol, dehidroepiandrosterone, prolactin, and complete lipid profile and clinical evaluations PANSS, PBRS, DAI, SIPS, SOPS SCS, and 2-COM CHECKLIST. Such determinations threw highly suggestive data fundamentally in the intramuscular administration branch with more favorable values in the biochemical variables, being without significant differences the clinical evaluations in both groups.

2. Susanne Fischer1
3. Eckart Rüther1, Prof.Dr.
4. Udo Reulbach2, Dr.

Objectives: There is a cumulative evidence (1) to suggest that atypical antipsychotics can increase risks of metabolic disturbances. Aims of the study were to investigate metabolic blood parameters and body weight in patients under treatment with olanzapine or quetiapine and to compare these results with plasma concentrations (therapeutic drug monitoring).

Methods: In a retrospective study totally 140 charts of patients treated with olanzapine (n=70) or quetiapine (n=70) were reviewed (Department of Psychiatry, University of Göttingen, Germany). Body weight (BMI) and levels of blood glucose, total cholesterol and triglycerides were evaluated and correlated with dosages and plasma concentrations (HPLC method with UV detection). Diagnoses, age, gender and comedictions were investigated.

Results: The olanzapine group (m:39, f:31, mean age:40.5 years, range:20-83 y) was matched with the quetiapine group (m:29, f:41, mean age:46.4 y, range:19-87 y). Main diagnosis of all patients was paranoid schizophrenia. Both samples were associated with weight gain (mean BMI under olanzapine 25.8, quetiapine 25.9) and hyperlipidemia without statistical differences between the drugs. There was an increased risk of hyperglycemia in olanzapine administration. Elevated BMI and triglycerides were observed in men. We found no statistically significant correlation between laboratory parameters and plasma concentrations, but high intra-and interindividual differences.

Conclusions: There was a risk for metabolic abnormalities associated with olanzapine and quetiapine, with olanzapine having a higher risk of metabolic syndrome. A metabolic monitoring of antipsychotic-treated patients and prospective investigations (2) in long-term treatments are recommended.

Introduction: recently, atypical antipsychotic like olanzapine are effective in the treatment of acute mania. In acutely ill patients with schizophrenia, olanzapine plasma concentration ≥ 23, 2 ng/ml have been identified as a predictor of clinical response. Aim: to determine a threshold of efficacy of olanzapine in a sample of in/out patients with acute mania. Patients and Methods: patients with acute mania were included and treated with olanzapine for 6 weeks; plasma concentration of olanzapine was measured by high-performance liquid chromatography. Clinical status was assessed by Young Mania Rating Scale (Y-MRS) and Clinical Global Impression (CGI). Results: a plasma threshold was determined to be 15,9 ng/ml about receiver operating characteristic curve analysis at 3 weeks of treatment. There was no correlation between the daily dosage of olanzapine and the plasma level (p< 0.05). Olanzapine plasma levels were not significantly different between responders and non responders. Conclusion: Our threshold is lower than those reported in schizophrenia. This may be related to lower dosage used in treatment in mania than in schizophrenia and particularly to the small number of our sample. Then further research on this specific issue is urgently needed.

TRIAL-BASED THOUGHT RECORD (TBTR): PRELIMINARY DATA ON A STRATEGY TO DEAL WITH CORE BELIEFS BY COMBINING SENTENCE REVERSION AND THE USE OF ANALOGY WITH A JUDICIAL PROCESS

INSTITUTIONS
1. Federal University of Bahia, Department of Neurosciences and Mental Health, Salvador, Brazil

AUTHORS
1. Irismar Reis de-Oliveira¹, Dr., MD, PhD, irismar.oliveira@uol.com.br

Objective. To propose the Trial-Based Thought Record (TBTR) - a modified, 7-column thought record addressing core beliefs by sentence reversion and analogy with a judicial process, inspired from Kafka’s novel “The Trial”, - and to present a demonstration video of a typical session.

Methods. Clients (n=30) participated in a simulation of a trial and exhibited shifts in their adherence to core beliefs and in the intensity of corresponding emotions after each step (investigation, prosecutor, defense attorney, prosecutor's second plea, defense attorney's second plea, and juror verdict) during a session.

Results. Significant mean reductions existed between percent values after investigation (taken as baseline) and defense attorney’s plea (p<0.001), and after the juror’s verdict, either in beliefs (p<0.001) or in intensity of emotions (p<0.001). Significant differences also emerged between the defense attorney’s first and second pleas (p=0.009) and between the defense attorney’s second plea and juror’s verdict concerning core beliefs (p=0.005) and emotions (p=0.02).

Conclusion. TBTR may help patients constructively reduce attachment to negative core beliefs and corresponding emotions.

Objective: To determine the efficacy and safety of escitalopram for preventing depression induced by pegylated interferon (PegIFN) alpha2a in chronic hepatitis C (CHC) patients.

Methods: CHC patients were randomized to receive escitalopram (15 mg/day) or placebo, double-blind, starting 2 weeks before PegIFN and continuing for 12 weeks. Main variables were incidence of DSM-IV major depressive episodes, and scores of MADRS and HADS questionnaires.

Results: 133 patients were included. Eighty-three (62%) patients were male, mean age 45.5 years. Placebo and escitalopram groups did not differ significantly in any measure at baseline. Only 1 patient (2%) in placebo group and 5 (8%) in escitalopram developed a major depressive episode (Chi square = 2.67, p = 0.11). MADRS increased between baseline and week-12 in 2.2 points with placebo and 3.1 with escitalopram. Figures for HADS’ depression subscale were 0.7 and 1.0 respectively. Differences were not statistically significant.

Conclusions: In CHC patients, pretreatment with an antidepressant is not effective for reducing depression induced by PegIFN and ribavirin, at least in a population of patients with low psychiatric risk. The use of escitalopram in CHC patients is safe regarding biochemical and virological response at week 12. This study has been supported by a grant from Roche Farma S. A. Escitalopram and placebo pills were provided by H.Lundbeck A/S.

ANTIDEPRESSANT PRESCRIBING ALTERS HYPNOTIC USE IN PRIMARY CARE

INSTITUTIONS
1. Liverpool John Moores University, School of Pharmacy & Chemistry, Liverpool, United Kingdom
2. King’s College, Institute of Psychiatry, London, United Kingdom

AUTHORS
1. John Donoghue1, john@johndonoghue.orangehome.co.uk
2. Malcolm Lader2, Professor, Malcolm.Lader@iop.kcl.ac.uk

Aims
UK prescribing guidelines state that benzodiazepines should be used to treat insomnia only when it is severe and for a maximum period of 4 weeks. However, in depressed patients, antidepressants may induce or exacerbate disturbed sleep. This study investigated the impact of antidepressant prescribing on hypnotic use in primary care in the UK.

Method
Data from 1996-2005 were obtained from the DIN-Link database (over 750,000 patients). Patients (>18 years) who received a new prescription for a hypnotic (no prescriptions for any benzodiazepine in the previous year) were included and followed for 1 year. Data were obtained on gender, age, depression status, antidepressant prescribed and length of hypnotic treatment.

Results
For each year of the study, irrespective of antidepressant prescribed, the prescription of an antidepressant was associated with an increase in the length of hypnotic treatment. In 2005, the proportion of depressed patients prescribed an antidepressant who received a hypnotic for more than 3 months was nearly 6 times greater, and those who received a hypnotic for more than a year was nearly 10 times greater than those not prescribed an antidepressant.

Conclusions
In depressed patients newly prescribed a hypnotic, the prescription of an antidepressant increases the length of hypnotic treatment. Antidepressants may exacerbate disturbed sleep in depression and prescribing guidelines on the use of hypnotics do not meet the needs of these patients.

MODERN APPROACH TO THE IRRITABLE BOWEL SYNDROME TREATMENT

INSTITUTIONS
1. City psycho-neurological dispensary, Rostov-on-Don, Russian Federation

AUTHORS
1. V. N. Sokolovskiy1
2. A. A. Doubonosova1
3. A. V. Krat1
4. M. A. Doubonosov1

In its core, the irritable bowel syndrome (IBS) is one of the forms of a somatoform vegetal dysfunction (as per ICD-10 F 45.3). Along the IBS symptoms, we usually distinguish the following: 1) objectively detectable vegetal manifestations (heavy heartbeat, sweatiness, facial hyperaemia, tremor); 2) non-specific vital dysfunctions in the gastrointestinal track (GIT) like: aches, feeling of discomfort, bursting sensation, diarrhea, constipation, increased mucus secretion. A crucial point here is an exact diagnostics, and a differentiation between an affective pathology (a depressive episode, recurrent depressive dysfunction), schizophrenic dysfunction, panic dysfunction and a generalized anxious dysfunction, somatoform, dissociated, and post-traumatic stress dysfunctions. The IBS treatment is a complex process, and, alongside with the influence on the GIT (by implementing antispasmodics, laxatives, ant-diarrhea drugs), it comprises a course of psychotherapy combined with psychotropic drugs: antidepressants, antipsychotics, and nootropes.

These measures can be provided by a multi-profile medical assistance from a psychiatrist, psychotherapist and gastroenterologist. Our experience of treatment of the patients suffering from IBS (318 patients of which 41% of men and 59% of women of 34+4.7 years of age) allows us to make a proposed scheme of a complex therapy. This could be as follows: a diet + psychotropic medicines (antidepressants combined with atypical antipsychotics) + drugs to help normalize the intestine motoric dysfunctions and microflora + a course of psychotherapy.

6. Jonathan Rabinowitz³, Prof., PhD, jr827@columbia.edu

Objective - Assess use of risperidone long acting injectable (RLAI) in recent onset psychosis.

Methods - This was a 24-month open-label non-randomized, single arm, single center study of 50 adults with newly diagnosed schizophrenia or schizophreniform disorder. Oro-dispersible risperidone (1 to 3 mg/d) was given through day 21. At day 7 the first injection of 25 mg of RLAI was given and every two weeks thereafter.

Results - 72% of patients (n=36) completed the full 24 month trial. Final dose for 54% of patients was 25 mg, for 30% 37.5 mg and for 16% 50 mg. There was significant improvement from baseline to endpoint on mean PANSS total (-39.7 sd 21.1, p<.0001), positive subscale (-15.3 sd 6.7, p<.0001), negative subscale (-7.6 sd 7.5, p<.0001) and general psychopathology subscale (-16.7 SD 10.1, p<.0001). 64% (n=32) of patients remitted (maintained for at least 6 months a “mild” or lower level on 8 key PANSS items), 23 of them by month 10. Adverse events (AEs) observed in at least 10% of patients were: blood prolactin increased, headache, sedation, influenza, parkinsonism, extrapyramidal disorder, aggression, insomnia, depression, blood cholesterol increased, psychotic disorder. Two patients suffered serious AEs (cerebrovascular accident and psychotic disorder) that resulted in discontinuation from study. At endpoint mean BMI gain was 4.8 sd 3.8 from 20.6 sd 4.6 at baseline (p<.001).

Conclusions - This study allows only for some tentative conclusions. Patients showed good symptom improvement, a favorable adverse event profile and compliance. Safety and efficacy in this population warrants further investigation in a controlled manner.

3. Luciane Wagner¹,³, Dr., MD, PhD, luciane.wagner@metodistadosul.edu.br

Introduction: In the south of Brazil, as a socioeducational attitude, the justice obliges adolescent violators to study. Incarcerated adolescents have an opportunity to attend a special and specific school located inside the prison institution

Method: this pilot cross-sectional study included 29 adolescents which are attending the special school and focused on aspects as the teacher evaluations of the students performance, impact of preview schooling, parents schooling, type of law violation, family history of law violation, abuse or dependence of substances, acquired benefits, and depressive and anxious symptoms severity (measured by Beck inventories).

Results: seventeen adolescents consented to participate. Teachers gave a general school performance of 6,53(SD=1,74) and they had previously studied a mean of 4,69(SD=3,3) years. Around 30% of the mothers and 12% of the fathers had their schooling known by the adolescents. Twenty nine percent had committed murder and 70% stole. Fifty six percent of the adolescents related that the relatives had committed any kind of law violation. Around 25% used cocaine, 50% cannabis and 70% related alcohol abuse or dependence. The mean score of depression severity was 21,06(SD=12,75) and the anxiety score was 10,31(SD=10,53). Fifty two percent acquired some kind of benefits according to their performance.

Conclusion: The acquisition of some prison institution benefits, the drug use/dependence, preview schooling, the parents schooling and depressive or anxious symptoms severity don't seems to be associated to the general school performance of adolescent violators.

THE EFFECT OF PHARMACOLOGICALLY SELECTIVE ANTIDEPRESSANTS ON MONOAMINE OXIDASE ACTIVITY

INSTITUTIONS
1. Charles University in Prague, 1st Faculty of Medicine, Department of Psychiatry, Prague, Czech Republic

AUTHORS
1. Zdeněk Fišar¹, Dr., CSc, zfisar@lf1.cuni.cz
2. Jiří Raboch¹, Prof., MD, DrSc
3. Zdeněk Hanuš³, Mr.

Aims According to the advanced monoamine theory (1), the activity of type-A monoamine oxidase (MAO) and density of serotonin transporters in the brain are crucial in the pathophysiology of depression. Accordingly, we studied the influence of antidepressants with different primary biochemical effects on the MAO activity in synaptosomes.

Methods We have used radiochemical methods to monitor the in vitro effects of 11 antidepressants and mood stabilisers on the activity of MAO-A and MAO-B in synaptosomes isolated from animal brains.

Results We observed the inhibition of MAO activity by pharmacologically selective antidepressants (tricyclic antidepressants, selective serotonin reuptake inhibitors, norepinephrine reuptake inhibitors, serotonin-norepinephrine reuptake inhibitors, noradrenergic and specific serotonergic antidepressants). Desipramine, amitriptyline, citalopram, and venlafaxine were the most effective MAO inhibitors of all the drugs which were tested. Most antidepressants inhibited MAO-A more than MAO-B. The inhibition was usually non-competitive.

Conclusion MAO activity can be used as a parameter which is sensitive to the action of most antidepressants. Our results support the advanced monoamine theory of depression (1) and the hypothesis of mitochondrial dysfunction in bipolar disorder (2). We assume that it is appropriate to continue testing the action of MAO-B in blood platelets of depressive patients as one of the potential markers which can be used for characterising subgroups of depressive disorders or predicting the effects of treatment with antidepressants.

This research was supported by the company Zentiva, a.s. Prague.

Literature data support the efficacy of psychoeducational therapy associated to pharmacological intervention also during the treatment of major depressive episode.

OBJECTIVE
The aim of the present study is to describe inpatient’s form of involvement with a weekly group psychoeducational therapy and the possible role of this strategy on relapse.

METHOD
85 patients hospitalized for a major depressive episode participated to psychoeducational group session conducted weekly by the equipe of the Mood Disorder Unit of San Raffaele Hospital in Milan. Their involvement with group psychoeducational sessions was assessed by professional educators using a rating instrument created on purpose. At discharge, patients filled in a ‘satisfaction questionnaire’ and WHOQOL, and remained in continuation treatment as outpatients for 9 months.

RESULTS
Data collected from ‘satisfaction questionnaire’ indicated patient’s high satisfaction about group psychotherapy. At the end of follow-up period, 40% of the sample relapsed. All clinical and social variables as well as the scores of the above-mentioned rating instruments were analyzed with of survival analysis to identify the ones that were possibly related to the risk of relapse. Among all the analyzed variables, patient’s ‘coherence’, ‘interest’, and ‘processing of information’ during therapy group and WHOQOL scores in ‘physical’ and ‘environmental’ areas were significantly related to the risk of relapse and re-hospitalization.

CONCLUSIONS
These results are an encouraging evidence of the cognitive support role of group psychoeducational therapy also during the acute treatment of depression and patient’s form of involvement with the group therapy could be considered as a long-term normothymia predictor.

Psychotherapy as a part of psychiatric treatment is related to similar problem in different institutions - departments, clinics and institutes. This is the problem of setting, that can be described as lack of possibility to organize stability of psychotherapeutic process in frame, time and place in certain cases, in public health care system. Psychotherapeutic setting refers, as practitioners say, to the physical framework and the routine procedures of practice which form an integral part of the process. Psychotherapy exists and works only when we offer our patients stability and continuity in place, time and number of sessions. Our experience shows that psychotherapeutic work in private practice is more stable and strictly defined, but our public health care system has to be organized in the better way with acknowledgement of demands for help from various kinds of patients. Work compares our experiences and unifies plans to specify setting in public health care institutions, as an integral part of mental health care reform in Serbia, which includes therapy, research and community orientation of psychiatry and psychotherapy.

4. Judit Tolna³, dr., MD, PhD, tolna@psych.sote.hu

**Background:** The diagnostic distribution of patients treated with electroconvulsive therapy (ECT) in Hungary is significantly different from that in Western-Europe or the USA. In Hungary most of the patients treated with ECT suffer from schizophrenia.

**Aim:** To analyze the practice of referring patients to ECT in Hungary.

**Methods:** A questionnaire containing socio-demographic data and items on the experience with ECT was mailed to all Hungarian psychiatrists working in psychiatric units where ECT is used (n=34). Respondents were asked to rate how often they consider ECT in various symptoms/syndromes. The main factors contributing to referrals to ECT were examined using factor analysis. Answers given by respondents in different positions and with different ECT experiences were also compared.

**Result:** A total of 78 questionnaires were returned from 14 departments; 94.5% of the respondents have ever administered ECT, 46.4% over the last year. Altogether 89% of the respondents ever referred patients to ECT, 54.8% in the last year. Respondents most frequently recommended ECT for antipsychotic and antidepressant-resistant cases, catatonic symptoms or patients with successful previous ECT.

**Conclusion:** In view of the high Hungarian suicide rate, surprising that ECT is rarely considered by the respondents in case of high suicide risk. Respondents also rarely consider ECT for NMS, or severe depression where ECT could be the first choice of treatment. The discrepancy between current referral practices and standard recommendations could be decreased with more ECT training courses.

OCULOLOGYRIC CRISIS WITH QUETIAPINE: A CASE REPORT

INSTITUTIONS
1. Assam Medical College, Department of Psychiatry, Dibrugarh, India
2. Assam Medical College, Department of Psychiatry, Dibrugarh, India

AUTHORS
1. Soumitra Ghosh¹, Dr., MD, drsghosh640@yahoo.co.in
2. Dhrubajyoti Bhuyan², Dr., MD, dr.dhrubajyoti@gmail.com

Introduction:
Oculogyric crisis is one of the distressing neurological side effects of dopamine blocking drugs such antipsychotic medications. It is characterized by bilateral dystonic elevation of visual gaze as well as hyperextension of the neck. It is thought to be very rare with atypical antipsychotics and is rarest with quetiapine. Indeed quetiapine is still believed to be the antipsychotic of choice in patient with history of oculogyric crisis.

Case report:
Mr. S.D., a 18 year old male from Nazira, Sivasgar, Assam, India was presented to the psychiatric OPD, Assam Medical College, Dibrugarh on 15.05.07 with a diagnosis of paranoid schizophrenia and was prescribed with 6 mg of Risperidone on which he developed ocular spasm. His medication was changed and was prescribed with 100 mg of quetiapine and 2mg Trihexiphenidyl. After a month tab Trihexiphenidyl was stopped following which he developed oculogyric crisis.

Discussion:
Oculogyric crisis has been reported with typical antipsychotics and also with some of the atypical antipsychotics like Olanzapine and Risperidone in various literatures. However, report with quetiapine is quite unexpected as it was believed to be the drug of choice in patients with a history of antipsychotic induced oculogyric crisis.

Our case report suggests that oculogyric crisis may be a rare phenomenon but it does occur with other atypical antipsychotics also.

A RESEARCH STUDY ON THE TRANSFORMATIONAL NATURE OF ANGER

INSTITUTIONS
1. Northern Illinois University, Counseling, Adult and Higher Education, DeKalb, Illinois, United States

AUTHORS
1. Francesca Giordano¹, Dr., PhD, fgiordano@niu.edu

The vast majority of the empirical literature on anger and its treatment has used behavioral, cognitive, or cognitive-behavioral theoretical perspectives. This paper will examine anger from alternative theoretical perspectives. This paper will first explore the aspects of anger suggested by feminist, multicultural, existential, and contextual family therapy perspectives. These aspects include anger and its connection to the gendered and cultural nature of the self; to unmet basic human needs and meaninglessness; and to the balance of relational boundaries. A qualitative research study was conducted. The individuals that were interviewed came from a variety of life situations in which they had experienced extreme anger-generating experiences they have successfully overcome. These situations were the result of political or social oppression, experiences with personal violence or other types of relational injury, or experiences with psychological or physical impoverishment. The findings were developed by examining these individuals who had experienced extreme anger-generating situations of unmet needs, injustice or relational injury and responded to these situations, over time, with positive life changes. These individuals had experienced these situations, yet responded with continued personal growth and adaptive life experiences, rather than responding with self-destruction, bitterness, or violence. Themes were developed to suggest that there are transformational aspects to anger. The findings from this study suggest that in some therapeutic situations anger can be used to facilitate personal growth rather than lead to aggression and conflict.

CASE STUDY: EFFICACY OF COGNITIVE-BEHAVIORAL THERAPY IN A SEVERE SELF-MUTILATION CASE.

INSTITUTIONS
1. University of Sao Paulo, Psychiatry, Sao Paulo, Brazil

2. Jackeline Suzie Giusti, Mrs, MD, jsgiusti@yahoo.com.br
3. Hermano Tavares, Mr, PhD
4. Euripedes Constantino Miguel, Mr, PhD
5. Sandra Scivoletto, Mrs, PhD

A particular psychotherapy for Self-Mutilation Behavior (SMB) was not mentioned in the literature until the present. Most studies describe the Dialectical Behavior Therapy and Psychodynamic Psychotherapy as part of treatment for SMB in patients with Borderline Personality Disorder (BPD). This case report describes the efficacy of Cognitive-Behavioral Therapy (CBT) in a 24-year-old woman, with severe SMB, without BPD. The patient was admitted to the multiple impulse-control disorder outpatient unit for treatment of SMB. This patient was submitted to the SCID-I/P, SCID-II/P, Y-BOCS, DY-BOCS, and Functional Assessment of Self-Mutilation (FASM) for diagnosis of SMB as well as comorbidities. The most frequently SMB presented was skin cutting which was associated with relief of feelings of ‘numbness’, self-punishment; and stopping bad feelings. Others comorbidities presented by her were Obsessive-Compulsive Disorder (OCD), Social Phobia, Bulimia, and Depression Disorder (DD). The treatment included CBT, nutritional orientation, and psychopharmacology. The techniques of CBT used were: skills training, homework assignments, symptom rating scales, and problem-solving strategies. After ten months of treatment the patient was stabilized in terms of DD, bulimic behaviors, and anxiety. OCD symptoms were mild, and SMB became rare. At this time there was emphasis in social skills, problem-solving strategies and emotion regulation at CBT. The CBT was maintained and after three more months of treatment she had stopped cutting herself and the OCD symptoms disappeared.

Conclusion: CBT shown to be effective in this case of severe SMB without BPD. In addition, this multidisciplinary approach may serve as a guide to treat severe SMB.

Aims: β-arrestins play a pivotal role in GPCR desensitization and down-regulation. Preliminary data from our laboratory indicates that chronic treatment with antidepressant drugs (ADs) affects β-arrestin1 rat brain levels. This study concentrates on ADs mechanism of action at the post-receptor level involving 2nd messenger systems, receptor down-regulation, and regulatory elements related to receptor-G protein signalling: β-arrestin1&2, especially their interaction with MAPK cascade components. Methods: C6 glioma cells were treated acute or chronically with various classes of ADs in the presence or absence of MEK1/2 inhibitor. cAMP levels were determined using a RIA-based assay. β-adrenergic receptor down-regulation was measured by radioligand binding assay. β-arrestin1&2 function and levels were measured by confocal microscopy and western blotting (WB). Results and Conclusions: cAMP level alterations in C6 glioma cells were found to be irrelevant to ADs therapeutic mechanism of action. No change was found in [3H]CGP-12177 binding capacity. Chronic exposure to ADs results in a significant increase in activated β-arrestin1 while causing a major decrease in the levels of both β-arrestin2 and functional ERK1/2. We conclude that β-arrestin2 acts as a cytosolic scaffold for activated ERK hence reducing ERK-dependent transcription. Inhibition of MEK1/2 caused a significant decrease in β-arrestin1 in both control and AD-treated cells. Unexpectedly, β-arrestin2 levels were unaltered during MEK1/2 inhibition alone, but were significantly increased in the presence of ADs, possibly through a non ERK-dependent pathway. ERK1/2 retention by β-arrestin2 presumably prevents ERK-dependent β-arrestin1 transcription. By reducing β-arrestin2 levels ADs enable activated ERK1/2 translocation to the nucleus, thus increasing β-arrestin1 levels.

4. Nada B Djordjevic1, Dr, MD, nadadjo@ptt.yu

Objective: Atypical antipsychotics (AAP) have been widely used for the management of patients with schizophrenia and other psychotic disorders, since they were introduced, during the past decade. AAP, as class, have demonstrated a significant advantage over conventional antipsychotics (CAP) in clinical efficacy and lower incidence of extrapyramidal symptoms and tardive dyskinesia. However, our clinical practice shows that certain AAP may be associated with a greater risk of weight gain and with drug-induced obesity.

Methods: This was a 6 month multicenter, prospective trial, which was active controlled, in patients with DSM-IV schizophrenia, who were drug free before hospitalization. We use WHO criteria: overweight as body mass index (BMI) of 25.0-29.9 kg/m², nd obesity as BMI more than 30 kg/m². Body weight was performed at baseline and at regular intervals during the study.

Results: The results we receive show that a greater proportion of patients treated with AAP exhibited clinically significant weight gain, at any point during the trial, compared with those treated with CAP.

Conclusion: AAP had a greater impact on patients weight than CAP. To prevent potential complications of obesity, patients should have nutritional counseling and exercise regimen, during the first year of medication with AAP.

2. Nai-Ying Ko3, Dr., RN, PhD
3. Wei-Chiang Yeh1, Dr., MD

Aim: Partnership in a holistic psychiatric care requires mutually-agreed goals between therapists and clients. Yet, career aspects are less emphasized when therapists work with people with severe mental illness (SMI). This study aimed to investigate the outlook on career development of patients who stayed long in a hospital-based day care program.

Method: Survey research was conducted. There were 106 participants in a day care program enrolled. An anonymous 20-minute questionnaire was conducted structurally by trained interviewers.

Results: Most participants (63%) had optimistic outlook for their future. Regarding Illness outcome, 30% of them thought they would recover fully, and 59% believed they should take medication lifelong. Regarding work, 49% wanted to have a regular job and 17% to have a part-time job; yet 64% wished to be independent financially. Regarding living, 80% would like to live with their primary family; only 17% to live independently. Regarding family life, 38% would like to marry and 20% to marry and have children; while another 38% to continue single status. The chi-square analysis revealed that satisfaction with current status was not associated with optimistic outlook ($\chi^2(2, N=104)=1.282, p=.527$). However, those who thought they have optimistic future were more likely to have positive outlook on their career development ($\chi^2(2, N=92)=28.815, p=.000$).

Conclusions: Most people with SMI want to have other roles than only as a patient. Instillation of hope and support are essentials to envision career development. Services should include trainings of effective communication and employment-oriented skills for people wishing to advance.

TRANSFORMING FROM HOSPITAL-BASED TO RECOVERY-ORIENTED: A PROGRAM EXPERIENCE

INSTITUTIONS
1. Chang-Gang Memorial Hospital-- Kaohsiung Medical Center, Department of Psychiatry, Kaohsiung, Taiwan Republic of China
2. Chang-Gang University, School of Medicine, Tiao-Yuan, Taiwan Republic of China
3. National Cheng Kung University, School of Nursing, Tainan, Taiwan Republic of China

AUTHORS
1. Su-Ting Hsu¹,², Dr., MD, ScD, hsust2000@hotmail.com
2. Wei-Chiang Yeh¹, Dr., MD
3. Yu-Hwa Chin¹, RN, MS
4. Nai-Ying Ko³, Dr., RN, PhD

Objective: Day care unit in hospitals has been the major service of rehabilitation programs in Taiwan. As long run, staff mindset and program structure adopt medical model inevitably. This report shares the experience that a day hospital strives to remodel as recovery-oriented rehabilitation program.

Process: This day hospital used to introduce educational model with emphasis on disease reduction and administrative management. Beginning with two full-time psychiatrists who trained with recovery model and rehabilitation employed, and expansion of services, the program structure and environment, as well as staff training, become the two major aspects of reform. Efforts on building therapeutic milieu include (1) clarifying missions of program as health promotion, skill development, and social participation; (2) providing choices of selecting psychiatrists and classes; (3) erasing the labeling of higher/lower functioning; and (4) introducing role models of recovery to clients and families. Efforts on staff training include (1) shifting focus from disease and symptoms to client strength and functions in meetings; (2) providing frequent group supervision; and (3) including employment and education as positive outcomes. For clients and staff, fear of losing structure and anxiety of moving forward pervaded in the first year. However, people and program make progress in the failure-free and person-centered atmosphere in the second year.

Conclusion: The benefit from being a “patient” in hospital is a significant barrier; yet to have positive outlook needs information and role models. For staff, skills development for promoting recovery requires inspirations from meeting role models, therapeutic environment where respects self-growth and supports self-efficacy for everyone, and continuation of consultation/supervision.

LONG TERM USE OF RISPERIDONE IN AUTISTIC PATIENTS: TEN YEAR FOLLOW-UP

INSTITUTIONS
1. Hospital Militar Central, Psychiatry, Bogota, Colombia

AUTHORS
1. Roberto E Chaskel¹, Dr., MD, chaskel@cable.net.co

22 autistic patients who started medication on Risperidone between ages 6-14 where followed after ten years of continued treatment. All laboratory screening tests where done after 5 and 10 years. Only a slight increase in lipid readings where found in patients 18 years and older. This suggests that positive metabolic findings start in early adulthood but do not appear in infancy and adolescence.

EFFECTIVENESS OF A SELF-CARE SKILLS TRAINING GROUP WITH A TOKEN ECONOMY SYSTEM FOR PATIENTS WITH CHRONIC SCHIZOPHRENIA

INSTITUTIONS
1. Changhua Christian Hospital, Department of Psychiatry, Changhua, Taiwan Republic of China

AUTHORS
1. Mei-Chueh Chen¹, Miss, 129828@cch.org.tw
2. Nan-Ying Chiu¹, Mr., MD, 11067@cch.org.tw
3. Lih-Haw Chao¹, Miss, 21728@cch.org.tw
4. Hsiang-Yi Chang¹, Miss, 97845@cch.org.tw

The purpose of the study is to investigate whether the grooming performance of patients with chronic schizophrenia can be improved after they participate in the self-care skills training group with a token economy system designed to reinforce their grooming performance. One-group pretest-posttest design was used in this study. Six patients with chronic schizophrenia participated in the self-care skills training group. The self-care training group meeting was held four times a week and lasted for ten weeks. Each group session was 30 minutes. The patients’ grooming and hygiene were evaluated every morning from the day a week before the group meeting to the last day of group meeting. The daily rating checklist includes items of hand washing, hair combing, hair washing, teeth brushing, face washing, dressing and bathing. In order to motivate the patients to learn and perform more skillful behaviors, tokens were given to them according to their attendance at group meeting and their grooming performance. Dependent-sample t tests were used to compare the weekly average grooming performance before and at the end of the self-care skills training sessions. There was statistically significant improvement in the overall performance and performance of teeth brushing, bathing, and hair washing. There was no statistically improvement in performance of dressing. The result indicates that self-care skills training group with a token economy system may be effective for improving the grooming performance of patients with chronic schizophrenia. A large sample size study should be carried out in the future.

CAN EMPIRICAL EVIDENCE BE USED TO PROMPTLY MODIFY PSYCHIATRIC PRACTICE? THE PARADIGM OF ATYPICAL ANTIPSYCHOTICS.

INSTITUTIONS
1. Barnet Enfield and Haringey Mental Health Trust, London, United Kingdom
2. Barnet Enfield and Haringey Mental Health Trust, London, United Kingdom
3. Eginition Hospital, Department of Psychiatry, Athens, Greece

AUTHORS
1. Nikolaos G Christodoulou¹, Dr., nikoschristodoulou@gmail.com
2. Hagen Rampes², Dr.
3. Vassilis Kontaxakis³, Prof.

Background: The use of atypical antipsychotics in schizophrenia was only recently challenged by hard evidence, despite a decade since their introduction. As empirical evidence can be produced faster than hard evidence, it may be used to modify clinical practice more promptly.

Aim: To investigate and discuss the potential role of using empirical evidence as a clinical practice modifier. A naturalistic study of the use of antipsychotics in Schizophrenia is presented as an example.

Methods. We conducted an analysis of the antipsychotic prescriptions of 150 inpatients with schizophrenia. The study took place prior to the publication of recent evidence which plays down the usefulness of the atypicals. The resulting trends, particularly regarding the use of atypical and conventional antipsychotics, were compared to current evidence-based practice, following the incorporation of the latest evidence to the latter.

Results. Our comparison shows that the study’s trends correlate partly with the current clinical evidence base. In particular, atypical antipsychotics were used significantly more often than conventional antipsychotics as first line therapy (p<0.001), but the overall prescription rates did not differ significantly between the two groups.

Conclusion. We suggest that empirical evidence may be useful as a prompt practice modifier. Ethical and practical considerations are discussed.

THE INSTALLATION AND FUNCTION OF A COOPERATIVE APARTMENT FOR CHRONICALLY MENTAL ILL INSTITUTIONS
1. General Hospital of Ioannina (G. Hatzikosta), Ioannina, Greece
2. Counselling Center for Combating Drug Abuse, Ioannina, Greece

AUTHORS
1. Lygeri Iliopoulou1,2, Dr, ssknni@otenet.gr
2. Foteini Dragatsouli1, Mrs, ssknni@otenet.gr
3. Androniki Fotiadou1, Dr, ssknni@otenet.gr

Objectives
The General Hospital of Ioannina has established Units of Community residences for chronically mental ill, falling within the scope to dwindle big psychiatric hospitals. We present here the process and the difficulties of the installation of four inhabitants from a long-term supportive living community residence to a cooperative apartment located in a block of flats in the town-center.

Method
Patients were chosen according to their level of function, illness process, age and compliance to the psychopharmaceutic therapy. They were also trained in housekeeping and social rehabilitation skills. During the first period, the therapeutic team was visiting the apartment daily and later these meetings became weekly.

Results
A problem for the staff and the patients was whether the inhabitants of the other apartments would be receptive to them. We took into great account the way in which we would deal functionally with this prospect without stressing or disappointing the patients. The initial resistance from some of the neighbors was faced by the display of good intention from the staff to inform them, to get to know each other, avoiding aggressive or defensive behavior. We chose to inform neighbors on an individual basis, since the minority of them who were prejudiced against mentally ill patients could influence others.

Conclusion
The successful psychosocial rehabilitation of mentally ill patients and their acceptance from the community in a state of independent living requires work with the patients themselves as well as with the environment in which they will be located.

6. Hitoshi Miyaoka1, Dr., PhD

Aim: Communication skills (CS) are important in various interpersonal settings such as the family, school, workplace, and community. There are few studies that investigated CS in various settings for different psychiatric diseases. Thus, we determined whether there are any differences in CS among patients with different psychiatric diseases in different interpersonal settings using the communication skills questionnaire (CSQ).

Methods: A comparison was made between the CS of 127 patients (33 schizophrenia, 33 depression, 31 neurotic disorder, 31 anorexia nervosa) and the CS of 90 healthy adults (control). CSQ included two interpersonal CS: cooperative communication skills (CCS) and assertive communication skills (ACS), which were assessed in six interpersonal setting (family, best friends, friends, superiors, neighbors, and strangers). Higher scores indicated better CS.

Results: All the patients with schizophrenia and eating disorders had significantly lower scores than the control in all the interpersonal settings. The patients with depression showed no significant difference from the control in only the ACS scores in the interpersonal settings with their superiors and neighbors, however, they had significantly lower ACS scores in all the other interpersonal settings. The patients with neurotic disorder had no significantly different scores from the control in the interpersonal settings with their family and friends, but had significantly lower scores in all the other interpersonal settings.

Conclusions: The different psychiatric diseases demonstrated different impairment patterns of CS. Knowing this, we will exert effort to develop an intervention method that exploits the features of the above psychiatric disorders.

USE OF AUTOANALYTIC PSYCHOTHERAPY (AAP) IN NON-Psychotic Disorders

INSTITUTIONS
1. Azerbaijan Medical University, Psychiatry, Baku, Azerbaijan

AUTHORS
1. Nadir Ismayilov¹, Professor

The AAT is an eclectic psychotherapeutic approach for treatment of mood, anxiety, somatoform and stress-related disorders. Therapeutic strategies of AAP include analysis of causes of psychiatric problems and elaboration of new coping strategies conducted by patients themselves. The method demonstrated significant improvement of symptoms in a relatively short period of treatment. The other advantages of AAT are related to validation of a patient’s autonomy and flexibility in therapeutic techniques application. AAP assumes that recovery may be achieved by comprehensive alteration of emotional, cognitive and behavioral patterns. AAT differs from other approaches in that the role of a therapist is to assist his patient to get over the symptoms independently as far as possible.

THERAPEUTICS FACTORS IN PARTIALLY HOSPITALISED INPATIENT GROUPS

INSTITUTIONS
1. KBC“Dr D. Misovic”, Hospital of psychiatry, Belgrade, Serbia and Montenegro

AUTHORS
1. Jasminka Aleksandar Jankovic¹, Dr, MD, nadja98@infosky.net

Day hospitals frequently have as a major purpose the facilitation of transition to community life. Day hospitals provide rich opportunities for these individuals, who may be half time patients and half time citizens of society at large. The atmosphere of partially hospitalisation is similar to the psychological phenomenon of transitional object as described by Winnicott. The staff members of the day hospitals or even physical structure itself become a transitional object for the patient-a mother image without the threatening characteristics of a real mother, an object the patient may love, interject, toss around, spit out, and take in again. Group process and group therapy play a major role in developing and sustaining the treatment in a day hospital. How does group therapy help patients in day hospitals?

Therapeutic change is an enormously complex process and occurs through an intricate interplay of various guided human experiences, which Yaqalom names therapeutic factors. There are eleven factors, and these factors may represent different parts of change, whereas others may be more accurately described as conditions for change. Patients in the same group may be benefited by widely differing clusters of therapeutics factors. Even among therapists who share the same ideology and speak the same language, there may be no consensus about why patients improve. Many more inpatients than outpatients select the therapeutic factors of hope and assumption of responsibility, and catharsis.

PERFECTIONISM AND TACTICS OF OBJECTIVE SETTING AMONG DEPRESSIVE AND ANXIETY PATIENTS

INSTITUTIONS
1. Moscow psychiatry research institute, Clinical psychiatry and psychology laboratory, Moscow, Russian Federation

AUTHORS
1. Tatjana Jurievna Judeeva, Mrs, MD, psyta@yandex.ru
2. Natalija Georgievna Garanian, Mrs., MD

Objectives: tactics of objective setting research among depressive and anxiety patients and their connection with perfectionism

Methods: Perfectionism questionnaire (developed by Garanian-Cholmogorova), aspiration level of Heckhausen (adapted by Kurek, 1987), BDI, BAI, SCL-90-R. Subjects: 89 depressive patients (ICD-10: F32, F33, F34), 93 anxiety patients (ICD-10: F40, F41, F42), 73 healthy control.

Results: Correlation analysis displays reliable connection between high general perfectionism figure and both aspiration for success and avoiding failure-leading situations. According to generally accepted attitude described in achievement motivation theory this style of acting in the situation of goal choosing is a protection against suffering a failure. According to strategy of goal choosing patients are ignoring the middle zone where difficult but possible to be done tasks lay, where their aspiration for success could be realized with high probability. Patients with high level of perfectionism are led by two contradictory aspirations - to achieve maximum, but not suffering a "failure feelings" at the same time. This forms a basis for their internal conflict.

Conclusions: Tactics of objective setting among patients differ from that among healthy people. In aspiration level experiment the range of difficulties chosen by patients was dramatically wider compare to the one in a normal group. Also alternation of very difficult (when failure of not achieving the goal is suffering not much) and very easy (when success is practically guaranteed) objectives choosing was registered.

Microglia has recently been regarded to be a mediator of neuroinflammation by releasing proinflammatory cytokines, nitric oxide (NO) and reactive oxygen species in the CNS. Microglia thus plays an important role as “SOURCE of FIRE” in the pathophysiology of neurodegenerative diseases such as Alzheimer’s disease and Parkinson’s disease. An accumulating body of evidence points to the significance of neuroinflammation and immunogenetics in schizophrenia. Therefore, “The FIRE” might also occur in the brain of patients with schizophrenia. In the present study, we investigated whether or not antipsychotics have anti-inflammatory effects like “FIRE EXTINGUISHER” on interferon (IFN)-γ-activated microglia in vitro. We thus measured the effects of typical and atypical antipsychotics on the generation of nitric oxide and inflammatory cytokine, tumor necrosis factor (TNF)-α from IFN-γ-activated microglia by using Griess assay and ELISA, respectively.

Especially atypical antipsychotics significantly inhibited the generation of nitric oxide (NO) and tumor necrosis factor (TNF)-α from IFN-γ-activated microglia. Antipsychotics have been regarded to have an effect mainly on neurons or neural networks including the synapse network for a long period of time. However, our findings have demonstrated that antipsychotics have an anti-inflammatory effect via the inhibition of microglial activation like “FIRE EXTINGUISHER” in the brain. Antipsychotics may therefore have a potentially useful therapeutic effect on patients with schizophrenia by reducing microglial inflammatory reactions, which may inhibit the process of neurogenesis and oligodendrogenesis. These results might shed some new light on the therapeutic strategies for the treatment of schizophrenia.

AUTHORS
1. Chul Kwon Kim, Dr., MD, kimck@dau.ac.kr, 2. GyunG ryul Kim, Dr., MD, 3. Jae Hong Park, Dr, MD

Objectives: Primary objective was to evaluate the impact of psychoeducation and drug side effects on inpatient psychiatric satisfaction with schizophrenic patients.

Methods: A 30-item multidimensional questionnaire for good validity and reliability was administered to schizophrenic inpatients (n=116) discharged from psychiatric ward to examine the satisfaction of inpatient service. All subjects were assigned into the psychoeducation group (N=49) and a customary ward meeting group (N=67). Each subject included in the psychoeducation group received twice weekly patient education until discharge. Those in the control group received supportive group meeting. There were no significant differences in the demographic and clinical variables such as sex, age, lengths of hospital stay, number of previous hospitalization, and duration of illness between psychoeducation and non-psychoeducation group. Whether the experience of drug side effect during hospitalization was assessed subjectively (Korean-version of Liverpool University Neuroleptic Side Effect Rating Scale) and objectively (chart review).

Results
1. Total score of service satisfaction scale of psychoeducation without experiencing severe drug side effect group was significantly higher than psychoeducation with experiencing severe drug side effect group, non-psychoeducation without experiencing severe drug side effect group, and non-psychoeducation with experiencing severe drug side effect group.
2. Total score of service satisfaction scale of psychoeducation with experiencing severe drug side effect group and non-psychoeducation without experiencing severe drug side effect group were significantly higher than non-psychoeducation with experiencing severe drug side effect group respectively.

Conclusions: This result suggest psychoeducation during hospitalization seems to compensate the negative effects of adverse drug reaction on the patient satisfaction of schizophrenic inpatient treatment.

DIFFERENTIAL SLEEP EFFECTS OF ESZOPICLONE TREATMENT AND DISCONTINUATION IN PATIENTS WITH PRIMARY INSOMNIA AND INSOMNIA CO-EXISTING WITH MAJOR DEPRESSIVE DISORDER OR GENERALIZED ANXIETY DISORDER

INSTITUTIONS
1. Duke University Medical Center, Durham, NC, United States
2. Massachusetts General Hospital, Boston, MA, United States
3. Sepracor Inc, Marlborough, MA, United States
4. Henry Ford Sleep Disorders Center, Detroit, MI, United States

AUTHORS

Introduction: Insomnia comorbid with psychiatric disorders remains poorly understood compared with primary insomnia (PI). In PI, sleep improves rapidly with eszopiclone therapy, is sustained with treatment, and diminishes with treatment discontinuation. We sought to determine whether this pattern also characterizes the treatment response of insomnia occurring with Major Depressive Disorder (MDD) and Generalized Anxiety Disorder (GAD).

Methods: We compared subjective sleep data from 3 randomized double-blind, placebo-controlled studies of eszopiclone: 1) PI patients received eszopiclone 3mg or placebo for 6 months (n=830); 2) MDD patients were treated with fluoxetine along with eszopiclone 3mg or placebo for 8 weeks (n=595). All studies included a 14-day single-blind placebo run-out period (MDD subjects continued fluoxetine and GAD subjects continued escitalopram).

Results: Eszopiclone significantly improved all sleep measures vs. placebo in all 3 studies during double-blind treatment (p<0.0001). Sleep latency (SL) and wake time after sleep onset (WASO) continued to improve to a greater degree after the first week of therapy in comorbid MDD compared with comorbid GAD and PI (p<0.05) patients. Sleep improvements observed vs. placebo during the double-blind period were consistently maintained following eszopiclone discontinuation only in comorbid MDD (p<0.05).

Conclusion: The pattern of the improvement in insomnia occurring with MDD differed from GAD and PI. Improvement in insomnia with eszopiclone was more gradual and better sustained after hypnotic discontinuation in comorbid MDD than in comorbid GAD or PI.

**EFFICACY OF ESZOPICLONE IN THE TREATMENT OF INSOMNIA: A SUBSET ANALYSIS BY BASELINE WAKE TIME AFTER SLEEP ONSET (WASO)**

**INSTITUTIONS**
1. Duke University Medical Center, Durham, NC, United States
2. Imperial College, London, United Kingdom

**AUTHORS**
1. Andrew Krystal
2. Stuart Montgomery

**Objective**: Insomnia agents are often used for the long-term treatment of chronic insomnia. Eszopiclone, a single isomer non-benzodiazepine, has demonstrated statistically significant improvements in measures of sleep and daytime function vs. placebo for up to 6 months, with no evidence of tolerance. Because WASO was not an entry criterion, subset analyses were conducted to determine the effect of eszopiclone in patients with more severe sleep maintenance insomnia.

**Methods**: Patients meeting DSM-IV criteria for primary insomnia entered a 6-month, placebo-controlled study evaluating the efficacy of eszopiclone 3mg in the treatment of chronic insomnia (n=548 eszopiclone; n=280 placebo). Patients were grouped by baseline WASO into Low-WASO (≤60 min; n=254) and High-WASO (>60 min; n=475) subgroups; endpoints evaluated were sleep latency (SL), WASO, and total sleep time (TST).

**Results**: Statistically significant differences (p<0.003) in favour of eszopiclone were noted between treatment groups for each subgroup at each month in all parameters. Results were similar over the 6-month treatment period (p<0.001): median WASO in the Low-WASO (eszopiclone: 14min, placebo: 24min) and High-WASO groups (eszopiclone: 25min, placebo: 52min); median TST in the Low-WASO (eszopiclone: 402min, placebo: 352min) and High-WASO groups (eszopiclone: 388 min, placebo: 328min). Patients taking eszopiclone in the High-WASO group had larger differences between treatments than the Low-WASO group for all parameters.

**Conclusions**: Eszopiclone 3mg was effective at reducing SL, WASO, and increasing TST in patients with high and low baseline WASO. This analysis demonstrates that the efficacy of eszopiclone on sleep maintenance was preserved irrespective of baseline sleep maintenance severity.

**Objective**: Present study was designed with an aim to elucidate the neuroprotective effect of citalopram and trazodone by using mice model of chronic fatigue syndrome.

**Materials and Methods**: Male albino lac a mice (n= 6 in each group) were forced to swim for 6 minutes session each day for 7 days and immobility period was measured on every alternate day. Citalopram (5 mg/kg, 10mg/kg) and Trazodone (5mg/kg, 10mg/kg) were administered each day 30 minutes before the forced swimming test. Different behavior tests such as locomotor (actophotometer), anxiety (mirror chamber) and memory were assessed using plus maze performance test. Immediately after behavior test, biochemical parameters were assessed from animal brains.

**Results**: Present study showed that seven day forced swimming caused a chronic fatigue syndrome like condition in animals. Chronic swimmmed mice also produced sever anxiety, impaired locomotor activity. Biochemical analysis revealed that chronic fatigue-induced stress significantly increased lipid peroxidation and nitrite levels and depleted reduced glutathione and catalase activity in fatigue brain. Pretreatment with citalopram (5 mg/kg, 10mg/kg) and trazodone (5mg/kg, 10mg/kg) for 7 days significantly reversed behavioral and biochemical changes.

**Conclusion**: Present study suggests that citalopram and trazodone pretreatment produced neuroprotective effect against chronic fatigue like behavioral conditions and oxidative stress in animals.

Polydipsia may lead to impaired consciousness and can be life-threatening. We report 2 cases of long-term polydipsia that were improved approximately 1 week after starting aripiprazole.

Case 1 was a 37-year-old female who developed polydipsia at 17 years old. Pharmacotherapy including haloperidol was started due to the presence of hallucination, delusion, and excitement. These symptoms gradually resolved, but severe negative symptoms remained. Polydipsia started to occur at 35 years old. Flunitrazepam 2 mg, zotepine 50 mg, risperidone 6 mg, and biperiden 3 mg were administered, but body weight gain remained at 5 to 10 kg/day. Water intake decreased 1 week after addition of aripiprazole 6 mg, and two weeks later body weight gain decreased to 0.74 kg/day. Aripiprazole 12 mg from week 4 and discontinuation of risperidone from week 9 improved polydipsia while maintaining a stable neurologic status.

Case 2 was a 48-year-old male who developed polydipsia at 18 years old. Haloperidol and sulpiride were administered to suppress auditory hallucination and delusion. Chlorpromazine, haloperidol, thioridazine, zotepine, and oxypertine were administered, but adverse reactions occurred. Polydipsia occurred at 34 years old when risperidone 2 mg was administered. Olanzapine 20 mg and floropipamide 100 mg were administered at 46 years old. Olanzapine was decreased to 10 mg and aripiprazole 3 mg was also prescribed in order to combat a water intake of 10 to 15 l/day, but without effect. Olanzapine was discontinued and aripiprazole was increased to 6 mg, and one week later the symptom disappeared. Subsequently, polydipsia improved while maintaining a stable neurologic status.

3. Tsung-Ming Hu 2, Dr., MD
4. Chin-Hung Liu 1, Mr., PhD
5. Ying-Lung Tseng 1, Mr., PhD
6. Hsien-Jane Chiu 1,2, Dr., MD, PhD

Aims/Objectives: Therapeutic drug monitoring data is useful for elucidating the time and pattern of drug use. This study is designed to establish a reliable method by using GC-Ms to detect aripiprazole in hair.

Methods: In this preliminary study, a new procedure, gas chromatography-mass spectrometry (GC-MS), is developed and validated for detecting aripiprazole and its main metabolite, dehydroaripiprazole, in hair. Total of 12 male psychiatric patients, who have been treated with aripiprazole at fixed dose (10-15 mg/day) for at least one month, were asked to donate 300mg hair after consent form completed.

Results: The mass spectra results showed that the characteristic ions for aripiprazole and dehydroaripiprazole were m/z 306, 292, 218 and 304, 290, 218, respectively. The limits of quantification (LOQs) evaluated in 50 mg of hair were 0.76 ng/mg for aripiprazole and 0.22 ng/mg for dehydroaripiprazole. Other reference parameters including selectivity, linearity, accuracy, precision and extraction efficiency were acceptable. The mean concentrations in hair of aripiprazole and dehydroaripiprazole were 61.8 ± 46.8 ng/mg (range: 17.57-189.71) and 48.58 ± 38.64 ng/mg (range: 6.37-152.61) respectively. Correlation between concentrations in hair of aripiprazole and dehydroaripiprazole (r = 0.928, P<0.01) is good. The concentration of dehydroaripiprazole in serum correlated significantly with the daily dose (r = 0.827, P=0.01).

Conclusions: This study demonstrated that hair analysis, especially for psychiatric patients, is a convenient, non-invasive, and validated approach to monitor patients’ compliance of aripiprazole prescription.

COMPARISON OF HYponATREMIA CASES FOLLOWING TREATMENT WITH SSRI/SNRI AND MIRTAZAPINE

INSTITUTIONS
1. Heinrich Heine University Düsseldorf, Germany

AUTHORS
1. Philipp Görtz, MD
2. Andreas Gillmann
3. Tillmann Supprian, MD
4. Christian Lange-Asschenfeldt, MD

Abstract Body:
Background/Aims: Hyponatremia (HN) is a recognized and potentially deleterious psychopharmacological side effect, particularly with SSRI and SNRI. Systematic data regarding hyponatremia with mirtazapine (MIR) are lacking.

Methods: Cases of HN (Na+ < 135 mmol/L) in psychiatric inpatients during a 18-month period (July 2005 through December 2006) were identified in a laboratory database. Demographic and treatment data (drugs, doses, combinations) were obtained by a consecutive chart review.

Results: HN occurred in 347 of 7113 patients (4.9%, aged 64.4 ± 16.8 years, 66% female). Of these, 51 (14.7%) received treatment with an SSRI or SNRI and 34 (9.8%) with MIR. There was no significant difference in age (67.2±14.6 vs. 68.9±12.6 years for the SSRI/SNRI and the MIR group, respectively) and gender distribution (74.5% vs. 76.5% female). Also, serum Na+, osmolality, and proportion of cases with clinically significant HN did not differ between the two groups, nor did the number of concomitant medical and psychotropic drugs and the number of comorbid medical diagnoses. Concomitant treatment with other drugs with a risk of HN (such as ACE inhibitors, diuretics, carbamazepine etc.) was compared. Psychiatric inpatients with HN following SSRI/SNRI received significantly more such comodication than those treated with MIR (p = 0.009, Mann-Whitney test).

Conclusions: There was no significant difference between the SSRI/SNRI and the MIR group regarding medical comorbidity, medical and psychotropic comedication, and severity of HN. However, HN following MIR treatment may occur with fewer concomitant risk drugs than following SSRI/SNRI treatment.

Management of psychosis in Parkinson’s disease (PD) is complex and includes elimination of identifiable risk factors, slow reduction of anti-PD medications and/or introduction of an atypical antipsychotic drug. It appears that the prognosis has improved with atypical antipsychotic therapy. The aim of this review is to investigate the latter and results are based on a Medline search for trials involving use of all atypical antipsychotics in psychosis in PD patients.

Clozapine is the best documented atypical antipsychotic shown to be effective against psychosis in PD patients. It improves tremor, does not induce deterioration of motor function, is safe at low doses but has an increased risk of leucopenia/agranulocytosis. Quetiapine seems to be well tolerated and effective although in two placebo controlled trials failed to show efficacy. Many patients are unable to tolerate risperidone due to deterioration of motor function. Olanzapine -possibly less than risperidone- also causes extrapyramidal side effects without significantly improving psychotic symptoms. Ziprasidone may be effective but has also been reported to induce deterioration of motor function. Preliminary experience with aripiprazole is mixed but not very encouraging. We conclude that based on trial-derived evidence for psychosis in PD, only clozapine -with its known limitations- can be fully recommended and quetiapine may be considered. Cholinesterase inhibitors have also, but with no consistent results, been reported to modestly improve psychosis in PD patients without an adverse effect on motor function. Electroconvulsive treatment is reserved for the severely psychotic depressed PD patient who cannot tolerate pharmacotherapy.

Males and females differ with regards to pharmacokinetic and pharmacodynamic factors and women experience adverse effects more frequently for numerous drugs. Sex was the strongest determinant of subjective tolerability of antipsychotics in a recent study (Barbui et al., 2005) and the authors suggested that studies should no longer consider men and women as a homogenous group.

The aim of this review is to investigate whether sex differences exist for susceptibility to adverse effects of second-generation antipsychotics (SGAs). Results are based on a Medline search for controlled trials involving all atypical antipsychotics.

Significantly higher plasma levels in women have been demonstrated for olanzapine and clozapine. There is—although controversial—evidence for more pronounced prolactin levels in females. Clozapine and olanzapine have been linked to greater weight gain with low pre-treatment body mass index and young age being risk factors for it. Females appear to be at greater risk, finding this effect particularly distressing. Some studies indicate that metabolic syndrome induced by SGAs is more frequent in females. The risk of corrected QT interval prolongation is again higher in females. Lastly, there is conflicting evidence for sex differences in SGAs causing extrapyramidal symptoms.

There is evidence suggesting sex-related variations in side effects of the SGAs. However, data are obtained by posthoc analysis and clinical trials of new therapeutic drugs have been conducted, for the most part, with male participants. Studies with a primary focus on sex differences are required and will help to determine how these differences should influence clinical management.

Long-acting intramuscular risperidone injection (RLAI) is a formulation that combines the benefits of atypical antipsychotics with improvements in compliance associated with depot formulations. We systematically followed-up 33 (24 male and 9 female) -according to DSM-IV- schizophrenic patients (paranoid:20, disorganized:10 and undifferentiated type:3), with average age 39.54 years (26-55) and average duration of illness 14.96 years (5-26), for more than 18 months.

Patients demonstrated a variety of reasons for receiving a long-acting injectable antipsychotic drug, including a history of non-compliance (57%), insufficient control of symptoms with previous atypical antipsychotics (28%), and adverse events with other treatments (15%). 21 (64%) patients were hospitalized when RLAI was initiated. The average dose of RLAI was 50.75mg every two weeks. Antipsychotic, anticholinergic or benzodiazepines coprescription was infrequent.

After more than 18 months of treatment (average duration of follow-up: 25.1 months, SD: 3.9, 18-32) 73% of the patients show significant and sustained clinical improvement in their symptoms over their original condition (CGI and BPRS score). These patients had no relapse or admission during this period despite their history of frequent exacerbations of symptoms and many hospitalizations. Treatment was well tolerated as demonstrated through the adverse event profile.

Long-acting risperidone injection seems to be an important advance in the management of patients requiring continuous antipsychotic therapy for long-term maintenance treatment. It seems to have the potential to extend benefits of assured medication delivery and improved long-term outcomes. Initiating it during inpatient treatment may be an important strategy in improving long-term outcomes among patients with schizophrenia.

IMMUNE REACTIVITY AND AMINOTRANSFERASES SERUM LEVEL DURING ATYPICAL NEUROLEPTICS TREATMENT OF SCHIZOPHRENIC PATIENTS

INSTITUTIONS
1. Mental Health Research Institute, Laboratory of Psychoneuroimmunology, Tomsk, Russian Federation

AUTHORS
1. Olga A. Lobacheva, Mrs., PhD, niipz@sibmail.com
2. Tamara P. Vetlugina, Prof., niipz@sibmail.com
3. Arkady V. Semke, Dr., MD, niipz@sibmail.com
4. T. G. Burdovitsina, Mrs., niipz@sibmail.com

Objective: The investigation of therapeutic efficiency, dynamics of immune parameters and aminotransferases serum level of schizophrenic patients during 6-week therapy atypical neuroleptics.

Methods: We examined 58 schizophrenics (22 patients - quetiapine (Seroquel) treatment, 12 - olanzapine (Zyprexa) treatment, 12 - risperidon (Rispolept) treatment, 12 - amisulprid (Soli-an) treatment) in two points: first - before the prescription of atypical neuroleptics, second - in 6 weeks of treatment. The psychometric estimation on scales PANS and CGI was used at clinical examination. We defined the parameters of cellular immunity (phenotyping of surface receptors of immunocompetent cells with using of homogeneous antibodies), humoral immunity (IgG, IgA, IgM, level of circulating immune complexes in blood serum) and serum levels of aspartate (ASAT) and alanine aminotransferases (ALAT) of schizophrenics.

Results: The research has revealed positive changes of psychopathological symptomatology on a scale PANS: decrease of the total estimation on 25-36%, a total number of positive symptoms - on 20-41%, negative - on 25-32% and general psychopathological - on 25-36%. In first point of examination of schizophrenics the T-immunodeficiency was determined; authentically high ASAT and ALAT levels were observed in groups of patients treated by olanzapine and quetiapine. Immunomodulatory effect on T-cells immunity after olanzapine and risperidon treatment and immunosuppression effect on T-cells immunity after amisulprid treatment is established. ASAT and ALAT levels reduced up to control indices during of olanzapine and quetiapine treatment.

Conclusion: Atypical neuroleptics render various influence on immune parameters. Dynamics of aminotransferases level which depends on their initial level is marked.

4. David L Franklin, Psy.D, dlfrankl@uci.edu
5. Glyndon D Riley, Ph.D
6. Charles T Nguyen, Dr., MD, tuantun@uci.edu

Introduction: To our knowledge, this is the first published case report regarding the use of aripiprazole for the treatment of stuttering.

Case Report: A 38 y/o Caucasian male presented with the diagnosis of stuttering (DSM-IV 307.0) since the age of 4. He had no prior psychotropic medication treatment for stuttering. The patient’s speech was assessed with the Riley Stuttering Severity Instrument-3 (SSI-3) immediately prior to initiation of pharmacotherapy. He was then started on aripiprazole 5mg/day. The patient reported side effects of mild akathisia and early morning awakening, which resolved after the first week on aripiprazole. Two weeks after initiation of aripiprazole, the patient’s speech was again assessed with the SSI-3. The patient’s total SSI-3 score was reduced from 43 (very severe) to 18 (mild) following treatment, a change of 58%. The percentage of syllables stuttered was reduced by 75%, the duration of the three longest stuttering events was reduced by 89%, and the physical concomitants score was reduced by 73%. Over the following six months, the patient’s aripiprazole dose was gradually increased to 15mg/day. He reported a subjective improvement in speech fluency and a decrease in social anxiety, with good tolerability.

Conclusion: We postulate that aripiprazole holds promise in the treatment of persistent developmental stuttering. Future double-blind placebo-controlled studies are needed to further evaluate the safety and efficacy of aripiprazole for the treatment of stuttering.

REHABILITATION OF CHRONIC PSYCHIATRIC PATIENTS AND ITS INFLUENCE IN DEMONSTRATING NEGATIVE SYMPTOMS OF SCHIZOPHRENIA

INSTITUTIONS
1. Special psychiatric hospital Dobrota, Kotor, Serbia and Montenegro

AUTHORS
1. Milica M Maric¹, Ms
2. Olivera Markovic¹, Mrs.
3. Milka Novovic¹, Dr.

The rehabilitation of chronic psychiatric patients has been organized before 4 years in the Special psychiatric hospital. The goal of research is to establish an evaluation action of applied rehabilitation methods in aim to reduce the intensity, so-called negative symptoms of schizophrenia. We have examined the group of 55 patients during the period of one year, both male and female from the age of 35 to 56, with diagnosis of a residual schizophrenia, which is diagnosed at least 5 years ago.

The following methods of rehabilitation have been applied: stimulation, reeducation, compensation and neurophysical rehabilitation. The effect is examined with scale of CGI and PANSS once a month. It is established the significant stalemate score on negative items of PANSS scale, after already two months of work, with slowly falling by the end of the year. Key words: schizophrenia, stimulation, reeducation, neuropsychological rehabilitation.

INJECTION-RELATED ADVERSE EVENTS OBSERVED WITH OLANZAPINE LONG-ACTING INJECTION

INSTITUTIONS
1. Eli Lilly and Company, Lilly Research Laboratories, Indianapolis, United States

AUTHORS
1. David McDonnell¹, Dr., MD, zyp_sci_comm@lilly.com, 2. Sebastian Sorsaburu¹, Dr., MD, 3. Elizabeth Brunner¹, Dr., MD 4. Holland Detke¹, Dr., PhD, 5. Scott Andersen⁷, Mr., MS, 6. Richard Bergstrom¹, Dr., PhD, 7. Malcolm Mitchell¹, Mr., MBBS 8. Kristen Ogle¹, Dr., PhD, 9. Mary Stickelmeyer⁷, Dr., PhD, 10. Susan Watson¹, Dr., PhD

OBJECTIVE. With any intramuscular product, there is a potential risk of injection site reactions. Another recognized potential risk of intramuscular products is inadvertent intravascular injection, the signs and symptoms of which depend on the formulation and safety profile of the injected medication. During clinical trials of olanzapine long-acting injection (OLAI) in schizophrenia, adverse events were identified that appeared related to intravascular injection of a portion of the dose.

METHODS. Safety data from completed and ongoing trials of OLAI were pooled in order to examine injection site reactions in all patients randomized to OLAI (8 studies, N=1,918) and in a placebo-controlled study (OLAI N=306, placebo N=98). A review of all adverse events possibly related to intravascular injection was also conducted.

RESULTS. Incidence of injection site reactions was 8.4% in all OLAI patients. In the placebo-controlled study, the incidence was 3.6% for OLAI and 0.0% for placebo (p=.073). Incidence of inadvertent intravascular injection was 25 events (in 24 patients) per 34,050 injections (0.07%). The 24 patients presented with symptoms consistent with excessive systemic olanzapine levels (eg, sedation, dizziness, confusion, slurred speech, altered gait, weakness, or unconsciousness). No clinically significant decreases in vital signs were observed. All 24 patients recovered completely with no permanent sequelae after 3-72 hours.

CONCLUSION. Rate of injection site reactions was low, with the majority being of mild severity. Rate of inadvertent intravascular injection was similar to a reported rate of similar events with IM procaine penicillin G. Recommended precautions include proper injection technique and a post-injection observation period.

EFFICACY AND SAFETY OF TRITTICO RETARD (TRAZODONE PROLONGED RELEASE) WHEN ADMINISTERED ACCORDING TO THE PRESCRIBING INFORMATION; POST-MARKETING SURVEILLANCE

INSTITUTIONS
1. Institute for Mental Health, Belgrade, Serbia and Montenegro

AUTHORS
1. Cedo Miljevic¹, Dr., cesne@ptt.yu

Objectives
To confirm efficacy and tolerability of Trazodone retard form when administered according to the prescribing information.

Methods
Open label multi-center post-marketing surveillance. 242 patients in 19 centers with diagnosis of major depressive disorder with or without anxiety according ICD-10. Subjects were treated with Trazodone retard form as monotherapy over 8-week period. The dosage scheme was:
- Day 1 to 3: 50mg
- Day 4 to 6: 100mg
- Day 7 to 14: 150mg
After day 14 the dose could be further increased to 300mg if patient did not show signs of improvement according to HAMD score.

Average age of study population was 48.62 years and 68% were women. 61.4% of the patients had their diagnosis already previously established. 95.4% had unipolar disorder while mean illness duration was 4 years and 8 months.

Results
HAMD, HAMA and CGI showed steady improvement over the study period. Average improvement in HAMD score was 63.5% and average improvement in HAMA score 63.9%. Both parameters showed statistically significant improvement already on the first post-baseline assessment on day 14 and remained stable until the end of the study. 54 patients did not show expected response up to the day 14 and were switched to increased dose. Severity of Disease decreased steadily while percentage of responders increased at each study visit.

Safety
52 patients have experienced adverse events, most common being headache, nausea, vertigo and sedation. This was consistent with other clinical studies with Trazodone.

Conclusion
Over the 8-week treatment period Trazodone retard form succeeded to steadily improve the main study parameters while keeping a satisfactory safety profile.

VALPROIC ACID-ASSOCIATED NON-HYPERAMMONEMIC ENCEPHALOPATHY: A CASE REPORT FROM THE PSYCHIATRIC SETTING

INSTITUTIONS
1. Psychiatric Hospital of Attica Dafni, 4th, Haidari, Athens, Greece

AUTHORS
1. Giorgos Mitropoulos¹
2. Ioannis Sovolakis¹
3. Ersi Tsopanaki¹
4. Christos Garnetas¹
5. Konstantinos Kontis¹

BACKGROUND: Valproic acid is an effective and well tolerated anticonvulsant, also used as a mood stabilizer and augmentation to antipsychotics. However it is associated with several neurological, haematological and other side effects. Among them encephalopathy, with or without hyperammonemia, is a rare but important clinical consideration. There is still no proof of causative effect of VA in patients with encephalopathy, but only an assumed causal relation.

PRESENTATION: We report the case of a 52-year-old, otherwise healthy, male patient who was hospitalised after an attempted suicide in the context of persecutory delusions. One month after admission 1000mg of VA were added as an adjunct to his antipsychotic medication (olanzapine 20mg) on the ground that he remained psychotic and at the same time marginally euphoric. Within less than a week he presented a rapid deterioration of cognitive functioning and impaired consciousness, until he became severely confused, and he remained so for virtually two months, despite the fact that all medication, save for VA, was gradually tapered off. There were no clinical or laboratory findings of hepatic impairment or other somatic disease, serum levels of ammonia were normal, brain lesion was excluded by CT and MRI, and EEG revealed moderate diffuse dysrhythmia. The situation resolved dramatically only when VA was discontinued and the patient returned within five days to his prior condition: psychotic, yet with a clear sensorium. One month later our patient was eventually discharged after having remitted under monotherapy with sertindole 16mg.

Microglia are the intrinsic immune cells and release many factors including proinflammatory cytokines, nitric oxide (NO) and neurotrophins after the disturbance in the brain. In addition, elevation of intracellular Ca\(^{2+}\) is required for the release of cytokines and NO from activated microglia. There is increasing evidence suggests that pathophysiology of psychiatric disorders, such as schizophrenia, depression or bipolar disorder, is related to the activation of inflammatory responses in the brain. We have recently reported that antipsychotics suppressed the release of NO and cytokines from activated microglia\(^1\). Brain-derived neurotrophin (BDNF) is a neurotrophin well known for its roles in the pathophysiology of psychiatric disorders. On the other hand, alteration of intracellular Ca\(^{2+}\) signaling also underlies the pathophysiology of psychiatric illness. BDNF increases intracellular Ca\(^{2+}\) in neurons and astrocytes. However, there have been no prior reports on how BDNF affects intracellular Ca\(^{2+}\) mobilization in microglia. We observed that BDNF induced sustained elevation of intracellular Ca\(^{2+}\), using the fura-2 imaging, in murine microglial cells. BDNF increased intracellular Ca\(^{2+}\) through the truncated neurotrophin TrkB receptors, activation of phospholipase C and store-operated calcium entry. We also observed that pretreatment of BDNF suppressed the generation of NO from activated microglia, while BDNF itself did not release NO. Our results suggest that BDNF could regulate the inflammatory responses via the modulation of microglial Ca\(^{2+}\) signaling in the brain. Moreover, BDNF-induced microglial Ca\(^{2+}\) elevation might have important roles in both pathophysiology and treatment of psychiatric disorders.

The Gross Motor Function Measure (GMFM-88) consists of four-points assessment system for every performed activities in lying and rolling up to walking, running and jumping skills, where criteria and conditions are described in details. Points gained are summed, a percentage against desired age level is calculated and it shows the developmental status of the child. This scale may be used to estimate both therapeutic aims and to assess the therapy progress of children with CP.

Aim of the study: to measure GMFM score in relation to incidence of epilepsy.

As research group 90 children were investigated, in whom CP was recognized. The incidence of epilepsy was noted acc. to the medical history of each child. All children were assessed using GMFM. The estimation used consisted of panel A- lying and rolling, including 17 items, panel B- sitting (20 items), panel C- crawling and kneeling (14 items), panel D- standing (13 items) and panel E- walking, running and jumping (24 items).

Results: Children in whom epilepsy was diagnosed showed slightly higher functional fitness. It seems interesting that epilepsy may decrease intellectual abilities, as well as manual function. It could be suggested that epilepsy is a (exaggerated / non-effective) trial to restore proper communication of neurons in the damaged brain, but this requires further study. It cannot also be excluded that epilepsy was diagnosed when presented to neurologist, but under proper treatment with no attacks its influence on brain is limited. In conclusion children with epilepsy because of motor deficits coexisted to mental problems need complex rehabilitation in all presented areas.

ESZOPICLONE CO-ADMINISTERED WITH ESCITALOPRAM OXALATE FOR INSOMNIA CO-EXISTING WITH GENERALIZED ANXIETY DISORDER (GAD): A SUBGROUP ANALYSIS

INSTITUTIONS
1. Imperial College of Medicine, United Kingdom
2. Sepracor Inc, United States

AUTHORS
1. Stuart Montgomery
2. James Roach

Objective: Results of a study in patients with comorbid insomnia and GAD showed that eszopiclone+escitalopram oxalate (ESZ+EO) co-administration produced greater improvements in sleep and anxiety compared with EO alone. This analysis evaluated whether baseline anxiety and sleep severity impacts the anxiolytic response.

Methods: Patients (18-64 years) met DSM-IV criteria for GAD and insomnia, with screening HAM-A total score ≥20. All patients received EO 10 mg QHS, and were randomized to ESZ 3 mg (n=294) or placebo (PBO, n=301) QHS for 8 weeks. Changes from baseline to Week 8 in HAM-A total score were analyzed in subgroups based on anxiety (HAM-A ≥median [n=326] or 14 [n=425] and ≤14 [n=143]) severity.

Results: The median HAM-A total score in both treatment groups was ~22. In patients with more severe anxiety, ESZ+EO was associated with significantly greater improvements in HAM-A relative to PBO+EO (mean reductions of -14.3 vs -12.5, respectively, p=0.01). Similarly, patients with more severe insomnia administered ESZ+EO had greater improvements in HAM-A versus PBO+EO (-12.5 vs -10.6, respectively; p=0.001). There were no significant differences between treatment arms in patients with less severe anxiety (-9.0 vs -8.5, respectively) or less severe insomnia (-10.6 vs -11.3, respectively). Improvements in SL over the 8 weeks of treatment were observed in all subgroups (p<0.05).

Conclusions: In this analysis, ESZ+EO co-administration in patients with more severe anxiety and insomnia was associated with significant improvements in anxiety, as measured by HAM-A total score, when compared with EO monotherapy.

ESZOPICLONE CO-ADMINISTERED WITH FLUOXETINE FOR INSOMNIA CO-EXISTING WITH MAJOR DEPRESSIVE DISORDER (MDD): A SUBGROUP ANALYSIS

INSTITUTIONS
1. Massachusetts General Hospital, Boston, MA, United States
2. Wake Forest University School of Medicine, Winston-Salem, NC, United States
3. Sepracor Inc, Marlborough, MA, United States
4. Imperial College of Medicine, London, United Kingdom
5. Henry Ford Sleep Disorders Center, Detroit, MI, United States

AUTHORS

Objective: In a study of eszopiclone+fluoxetine in comorbid insomnia and depression, co-therapy produced greater improvements in sleep, including sleep maintenance, and a measure of depression (Hamilton Depression Rating Scale; HAM-D17) versus fluoxetine monotherapy. This analysis evaluated whether baseline sleep severity impacts the treatment response.

Methods: Patients met DSM-IV criteria for MDD and insomnia, with screening HAM-D17 (excluding sleep items) >14. All patients received fluoxetine QAM, and were randomized to ESZ 3mg (n=270) or placebo (n=275) QHS for 8 weeks. Changes in wake time after sleep onset (WASO) and HAM-D17 total score were analyzed in subgroups based on total sleep time (TST) >6hours (n=62) or TST≤6hours (n=467). Data were analyzed using ANCOVA.

Results: At baseline, WASO was worse in patients with TST≤6hours vs TST>6hours (80min vs 40min, respectively), but HAM-D17 total scores were similar (mean 22). Post-treatment, larger improvements with eszopiclone+fluoxetine vs placebo+fluoxetine were generally observed across endpoints. For the TST≥6hour group, there were significant differences between eszopiclone+fluoxetine and placebo+fluoxetine for WASO (average over 8 weeks: medians of 27min vs 43min, p=0.0001) and HAM-D17 (mean reductions at Week 8: 13.7 vs 11.5, p=0.004). Similar findings were noted for the TST≤6hour group (WASO: 15min for co-therapy vs 35min for monotherapy; HAM-D17 reductions: 13.0 vs 11.3, respectively), although the treatment differences were not significant due perhaps to the small sample sizes in this subgroup.

Conclusions: In this analysis, regardless of TST severity, eszopiclone+fluoxetine co-therapy provided significant improvements in sleep maintenance and HAM-D17 relative to fluoxetine monotherapy.

IMPACT OF ANTIPSYCHOTICS ON BIOLOGICAL PARAMETERS OF SCHIZOPHRENICS DURING SIX MONTHS OF USE

INSTITUTIONS
1. College of Medicine Tanta university, Psychiatry, Tanta, Egypt

AUTHORS
1. Ahmed Mubarak¹, PRof., MD, ahmed_mubarak@hotmail.com
2. Hossam El Sawy¹, Dr, MD
3. Heba Murad¹, Dr

Purpose of the study: to see the impact of the different antipsychotics on biological parameters

Methods: 161 patients who met DSM-VI-TR criteria of schizophrenia: 59 treated with haloperidol. 48 patients with clozapine 45 patients with risperidone and 9 patients on olanzapine for a period of 6 months. Blood glucose, lipid profile, liver enzymes weight gain, waist circumference and EKG were tested at the beginning, 3and 6 months of treatments. These parameters were compared with 50 healthy control.

Results: Significant increase in fasting blood glucose, blood cholesterol, triglycerides and body weight, other parameters showed non significant increase in schizophrenic than control all these increments were not reaching pathological levels. After 6 months period showed that; blood glucose is gradually increases in those treated with haloperidol and clozapine but by the end of 6 months this returns back to average level. The blood cholesterol showed significant (p<0.05) rising in all patients while TG increased significantly (p<0.05) only in those treated with clozapine and olanzapine, these changes were persistent till the end of the study (6 months). Comparing each drug, we found that, rise in blood glucose was more in those with haloperidol compared with other drugs (p<0.05) while TG showed the reverse. Blood cholesterol is relatively more in those treated with olanzapine if compared with clozapine or haloperidol. LDH is significantly elevated with clozapine and haloperidol (P<0.05), while HDL is more with risperidone.

Conclusion: From this study we concluded that the changes in studied biological parameters could not be simply attributed to the antipsychotics

EGO FUNCTIONS IN OPIOID DEPENDENT PATIENTS

INSTITUTIONS
1. University of Kentucky, Psychiatry, Lexington, United States

AUTHORS
1. Daniel D Nahum¹, Dr, MD, pshnahum@email.uky.edu

Aims:  
1. Demonstrate a novel technique of Ego Function Assessment (EFA).
2. Compare the Ego Functions of Opioid Dependent (OD) patients to the general patient population.
3. Explore the psychotherapeutic role of EFA in the treatment of OD patients.

Methods: Workshop will start with a discussion of ego functions as described by Bellak. Presenter will than illustrate a computer-assisted self-report version of the EFA. Twenty-four OD patients undergoing treatment with buprenorphine in a university outpatient clinic, completed the EFA. The ego functions of OD patients were compared with those of a general outpatient puation to explore if the OD group exhibited a unique pattern. How their responses were utilized, to explore their specific ego vulnerabilities and how these relate to their substance use and overall adaptation, will be discussed. Finally the psychotherapeutic utility of EFA will be described.

Conclusion: This computer-assisted self-report assessment of the ego functions was found to be a practical technique of evaluating and addressing specific ego difficulties in OD patients. Initial comparisons with the general outpatient population supports findings previously described in the literature, that OD population has a unique ego function profile. Exploring this profile with patients can be a useful psychotherapeutic device.

TREATMENT OF ORGANIC DELUSIONAL [SCHIZOPHRENIA-LIKE] DISORDER WITH ARIPIPRAZOLE. CASE REPORT

INSTITUTIONS
1. VMA-Sofia, Psychiatry, Sofia, Bulgaria
2. VMI-Pleven, Psychiatry, Pleven, Bulgaria

AUTHORS
1. Tony S Donchev¹, Dr, MD, PhD. tonyd@abv.bg
2. Vladimir V Nakov², Dr., MD. vnakov@gmail.com

Aims
Secondary psychotic syndromes were categorized in DSM-II as psychoses associated with organic brain syndromes. The syndromes included in that category were the dementias, deliria, and psychoses associated with other cerebral and systemic conditions. The term “psychosis” continued to be used for the sake of historic continuity, with the acknowledgment that “many patients for whom these diagnoses are clinically justified are not in fact psychotic. In DSM-IV, psychotic disorder due to a general medical condition (with its available subtypes) has been moved out of the organic group to the phenomenological cluster to which it is related.

Methods
We report a case of a 49 old woman initially presenting with psychiatric symptoms, favourably influenced by application of aripiprazole.

Results
The patient's problems had begun six months to hospital admission with symptoms of hallucinations, behavioral disturbances and cognitive symptoms. She was treated initially as a psychiatric outpatient receiving clonazepam, haloperidol, amisulpiride, levomepromazine. During the implemented examination, diagnosis was clarified and the therapy switched to aripiprazole.

Conclusion
The principles of treatment for a secondary psychotic disorder are similar to those for any secondary neuropsychiatric disorder, namely, rapid identification of the etiological agent and treatment of the underlying cause. Antipsychotics medications afford empirical symptomatic treatment for the psychotic symptoms, although secondary psychotic disorders often prove more refractory than idiopathic disorders to such treatment. Patients with primary systemic or cerebral diseases frequently are more vulnerable to the untoward adverse effects of antipsychotic drugs.

ESCITALOPRAM AND QUALITY OF LIFE

INSTITUTIONS
1. National University of Cuyo, Neuroscience and Medical Humanity Institute, Mendoza, Argentina

AUTHORS
1. Jorge Nazar¹, Dr. Emerit Professor, jorge_nazar@hotmail.com

In the last years, the appearance of selective serotonin reuptake inhibitors and specific behavior therapy have offers to the patients, better quality of life (QL) than the treatment with TCA or IMAOs. SSRIs, have became widely used in the treatment of depression and anxiety. This evaluation focuses on the improved tolerability of SSRI and the resulting improved treatment adherence.

"Patients receiving treatment with SSRI are more likely to receive an adequate dosage that is sufficient to achieve symptom remission and prevent relapse or recurrence than are patients being treated with a TCA. (Baker et al, 2001).

Now we are reporting the result of the evaluation of the Quality of Life of 205 patients with Mood Disorders and Anxiety Disorders who have received treatment with Escitalopram (SSRI), during one year.

This study determines the relation between the use of Escitalopram (SSRI), and the Quality of Life of the patients during the treatment. The Quality of life of patient was evaluated at the beginning, at middle and at the last of the treatment.

Result:
the following scale and form have been applied:

a) Diagnosis form.
b) Clinical and Psychiatric examination.
c) Hamilton Scale (Depression and Anxiety).
d) G.C.I.
e) Quality of Life Scale.
d) SAAS Scale (Social Activity Scale).

Conclusion:
1 Escitalopram gave to the patients a Maintain Remission.
2 Excellent Recovery of depressive and anxiety symptom.
3 Excellent Compliance. 195 patients concluded the treatment after one year.
4 Excellent profile of Side Effects.
5 The patient fell an excellent Quality of Life.
6 Excellent Tolerance. (Light level of Advers Effects: only three patients suffered headache)

STEVENS JOHNSON SYNDROME - TOXIC EPIDERMAL NECROLYSIS INDUCED BY COMBINATION OF LAMOTRIGINE AND VALPROAT

INSTITUTIONS
1. Bakirkoy Research and Training Hospital for Psychiatric and Neurological Diseases, Psychiatry, Istanbul, Turkey
2. Istanbul Research and Training Hospital, Dermatology, Istanbul, Turkey

AUTHORS
1. Serap Oflaz, Mrs, MD, drserapb@yahoo.com
2. Hira S. Kalkan
3. V. Kirkor Kamberyan
4. Esra Gökçe
5. M. Salih Gürel
6. Medaim Yanik, Mr, MD, myanik@gmail.com

Introduction: Stevens-Johnson syndrome (SJS) is a rare but life-threatening acute allergic reaction affecting the skin and mucous membranes. Stevens-Johnson syndrome is considered a milder form of Toxic Epidermal Necrolysis (TEN). If affected body surface is 10-30%, this condition is said to be SJS-TEN.

Aims: A case of lamotrigine and valproat induced SJS-TEN is reported

Summary: A 24-year-old woman with psychotic depression arrived at the emergency service with suicidal plans, oral mucosal lesions and generalized rash. Her treatment at admission included lithuril 900mg, valproic acid 1000mg, risperidon 6mg and lamotrigine - which was added two weeks before - 50mg p.o daily. The patient's medications were stopped except antipsychotics and additionally intravenous fluids, antibiotics, antiaggregants, and steroids was given. Dermatological symptoms resolved in 10 days. Electroconvulsive therapy was applied. After 25 days, the patient had a sufficient recovery and was discharged.

Conclusion: The present case report supports the clinical evidence that combination of lamotrigine with other psychiatric drugs increases the frequency and severity of skin reactions. Therefore in polypharmacy, lamotrigine should be used more carefully and the treatment should be discontinued if any rash appears.

Lithium has been used widely for the treatment of recurrent manic-depressive illness; however, there are some reports that long-lasting neurological sequelae could be caused by lithium intoxication. The clinical picture of sequelae is cerebellar affection: scanning speech and ataxia.

The following is a case-report of a patient who had been under high dosage lithium treatment for almost 30 years in another hospital - 1500mg lithium maximum - who presented the neurological sequelae.

For the treatment of sequelae, drug treatment is not effective but physiotherapy, speech therapy and general rehabilitation can improve overall performance. This patient had recurrent manic episodes every 3 months and we tried to control this with sodium valproate and clonazepam, with little success. Since there is no effective drug treatment, and some drugs, especially haloperidol, worsen the symptoms, it is more difficult to control recurrent, severe episodes and their sequelae. The treatment for this case will be discussed.

2. Gorkem Ugurlu, Dr, MD
3. Asena Akdemir, Dr, MD
4. Sibel Orsel, Dr, MD
5. Mustafa Ugurlu, Dr, MD

Introduction:
The etiology of the edema with risperidone could not be clearly determined in most of the cases in the literature. Some of the previous cases of edema due to risperidone involved risperidone combined with other psychotropic medications. Another mechanism that could be responsible for edema with risperidone are immunological mechanisms, especially Type I and Type IV allergic reactions (1). Edema due to risperidone may occur dose-dependently. As the dose of risperidone used in the treatment increases, the risk of edema was reported to be increased (2).

Cases:
Our report describes facial and periorbital edema with risperidone therapy in three patients that faded away with risperidone discontinuation. The patients were not using any other drug concomitantly with risperidone ruling out the possibility of a drug interaction or additive effect of another drug. In two of three cases C3, C4 and C1 esterase and Ig E levels were within normal limits. Also in our cases, the doses of risperidone were within the recommended therapeutic limits.

Conclusion:
Despite the rare occurrence of edema in patients receiving risperidone treatment, this adverse effect should be taken into account in order to avoid unnecessary complicated laboratory assessments and as it might affect patient compliance with treatment.

We have studied electroconvulsive therapy application in a 24 patient psychiatric ward during the period between 2000 and 2007.

In our sample, consistent on 70 electroconvulsive cycles applied in 53 patients applications, the measured variables were: gender, age, diagnosis, previous processes, previous administration of ECT, duration of the present episode, previous treatment before ECT including drugs used and treatment compliance, average number of ECT applications, response to the administration, treatment at discharge and evidence of the appearance of subsequent psychogenic deficit.

Average age of patients treated with ECT was 55,81 years, being mostly women (67,14%). Diagnosis in our sample were melancholic, psychotic or non psychotic (41,42%) and manic depressive psychosis or schizoaffective psychosis, most frequently in a depressive episode, although also during manic or mixed episodes. Schizophrenic psychosis only takes up a discreet percentage of the sample (11,42%)

Average of applied sessions was 5,52 sessions per patient, obtaining very successful results in most cases (92,86%). Globally, the ECT was well tolerated specially in those cases in which the process that justified ECT were not associated to previous persistent intellectual deficit. From these patients just five of them had post-ECT administration confusional symptoms. We found manic symptoms in five cases.

Electroconvulsive therapy was administrated as prophylactic intervention in several melancholic patients and as maintenance therapy.

Representation about stages of rehabilitation gives division of process into consecutive stages: regenerative treatment, readaptation and rehabilitation literally this word. At the first stage - regenerative treatment - the task will consist in a reduction of semiology, preventive maintenance of the subsequent frustration and complications; at the subsequent stages the task consists in the adaptation of an individual by a life and work, in the rational household and labour device, in creation of a favorable psychological and social microhabitat.

Objective: 112 patients with nonpsychotic mental disorders - 44 men, 68 women.

Methods: a clinical method, psychodiagnostical and psychotherapeutic methods.

Results: During treatment the sequence of 4 stages of influence has been used: 1) dezactualization neurotic semiology; 2) symptomatic psychotherapy; 3) social - psychological correction; 4) fastening psychoprofilactic skills with the help of psychotherapeutic methods depending on a psychopathological syndrome. In system of complex improvement of patients the psychotherapy is one of the basic means of treatment and preventive maintenance. At a choice of methods of psychotherapy, physiotherapy, medicamentous means features of forms of current of diseases and specificity of work, a somatic condition of the patients, surrounding them micro- and macroenvironment were taken into account.

Conclusions: Realization of the concept of rehabilitation in modern conditions demands formation of a new professional psychiatric paradigm, development and introduction of new organizational forms of rendering of medical aid and adequate change of system of the professional training, participating in rendering assistance by the patient with mental frustration.

THE SYSTEM AT ABILITATION MENTAL DISORDERS

INSTITUTIONS
1. Donetsk National Medical University by M.Gorky, Rehabilitation and Diagnostic Center Ministry of the Health of Ukraine, Donetsk, Ukraine

AUTHORS
1. Oleg A. Panchenko1, Dr., Prof., rdckonst@mail.ru

The role abilitation as new direction in development of public health services is defined first of all that in effect it assumes not restoration of the lost or broken mental or physical functions, and training of the person to methods of the decision of problems arising with health, development of new opportunities and the abilities compensating a pathology, resorting to the help of the expert. The tasks of clinical-psychological abilitation are:

1. Prevention of occurrence of disease - it’s a methods and strategy abilitation which help to warn various types of disorders. Realization of this function promotes preservation of mental, physical and social health.
2. Correction of mental disorders on a structure of disease. The purpose of this function - therapy of disorders and by that decrease in absolute number of diseases.
3. Readiness for return development. In the widest sense, the purpose of rehabilitation - to help the person to put in full anew into operation, social sphere and a society after frustration or illness has appeared or if there is a physical or intellectual insufficiency. Due to this long-term consequences of any frustration or illness should be or are prevented, or - at chronic, incurable frustration - are softened or shown to a minimum.

If now the system of rehabilitation is widely developed, abilitation it concerns to strategy to a lesser degree, especially it concerns system abilitation mental disorders. This problem demands the further theoretical analysis supported by results of practical scientific researches and technological development medico-psychological and psychophisiological of the plan.

9. Sarantos Barbagiannis¹
10. Theodoros Kostis¹

Aim: State our own experience in group music therapy among colleagues in Piraeus General Hospital, Psychiatric unit, Greece.

Method: Group size was 10 permanent participants’ doctors specializing in psychiatry. Therapy duration was 6 months, 75’ per session. Frequency: 1 session per week. The technical order of the groups was circular directed by two coordinators. The method used was Guided Imagery in Music by H. Bonny. The first 20 minute of each session include listening to music selected by group members or coordinators.

Results: Music listening functioned as an acceptable element between members in order to express transference or anti-transference feelings. According to a given questionnaire 100% of the members stated that Music listening was the basic element of the group, brought musical selection and asked for extension of the time duration of the group. 58% stated that they developed closer relationship with their colleagues and 91% that they improved the level of their self-knowledge. 75% stated that they plan to have psychotherapy in the near future. One female participant decided to get married.

Conclusion: It seems that Guided Imagery in Music (GIM) groups, help in the creation of meaningful relationships between colleagues in working environment. Music functions as a catalyst accelerating the procedures of self-knowledge. GIM groups may constitute as an introductory stage towards Dynamic Psychotherapy of those engaged in Psychiatry. GIM groups can have application on other working environments as well, improving relations among colleagues.

Aims: Standard antidepressant treatment was found to fail in 30–40% of patients with depressions. Multiple complex factors may govern individual drug response and could affect the positive outcome of therapy, resulting in lack of efficacy, often switch to another antidepressant, higher risk of adverse drug reactions (ADRs) and compromised patient compliance. This pilot study follows up the influence of different factors, such as age, gender, comorbidity, concomitant drug treatment and genetic variations on antidepressant efficacy and safety, as well as compliance with therapy.

Methods: Six-month opened prospective study was carried out in a psychiatric office by a team of psychiatrist and clinical pharmacologists. Outpatients with depression were enrolled in order of attendance, according to inclusion criteria. Hamilton Rating Scale for Depression (HRSD) was applied for rating the severity of depression. DNA analysis protocol for genotyping of drug metabolizing enzymes is currently approbated and tested in healthy controls by molecular biologists.

Results: Eighty depressive outpatients (35 male, 45 female) with HRSD ≤ 16 on day first were followed up for antidepressant efficacy, safety and patient compliance. Medication history, potential substance abuse, concomitant drug therapy and ADRs to antidepressants were documented. Analysis of detected drug metabolizing enzymes polymorphisms and their potential role in antidepressant drug response is in process.

Conclusions: Preliminary study results suggest that age, gender, comorbidity, concomitant drug use and genetic variations may have a complex influence on the treatment outcome of depressions and should be considered in optimizing the individual patient drug response.

Keywords: depression, antidepressant treatment, drug response.

ANXIETY AND FUNCTIONING WITH PATIENTS TREATED COGNITIVE- BEHAVIORAL THERAPIES AND BY PSYCHOPHARMACOTHERAPY; COMPARATIVE ANALYSIS

INSTITUTIONS
1. University Clinical Center, Psychiatric Clinic, Tuzla, Bosnia and Herzegovina
2. Department of Neuropsychiatry of Primary Health Centre, Tuzla, Bosnia and Herzegovina

AUTHORS
1. Jasna Petkovic, jovana.p@bih.net.ba
2. Emir Tupkovic

Aims: We compared 30 patients with anxiety disorders, treated with cognitive-behavioral psychotherapy (CBT) and psychopharmacotherapy (Group I) with 30 patients with only psychopharmacotherapy (Group II)

Methods: For 18 months there have been used Beck Anxiety Inventory (BAI), and Global assessment of functioning (GAF) on the beginning, at the end of treatment and 6 months after treatment.

Results: At the beginning of treatment in first group GAF showed negative correlation in comparison with BAI (r = -0.60). In second group GAF showed negative correlation in comparison with BAI (r = -0.60). After one year of CBT and psychopharmacotherapy mean value of improvements in first group were BAI 38.2 ± 12.6, GAF 23.9, and correlation of GAF with BAI was low (r =-0.28). In second group mean value of improvements were: BAI 24.1 ± 13.3 (significantly lower than in first group; p< 0.0001, GAF 13.2 ± 5.4 (significantly lower than in first group; p< 0.0001, with BAI (r = -0.56). Six months after therapies all parameters in first group were significantly worsen: BAI 4.5 ± 2.0, and GAF -6.9 ± 5.4. At this stage GAF no correlations with BAI (-0.10), Similar worseness of all parameters after 6 months was in second group: BAI 4.2 ± 2.8, and GAF -5.0 ± 1.4, but GAF still correlated with BAI (-0.39).

Conclusion: The combined approach of CBT and drugs is better then drugs alone in the treatment anxiety disorders. GAF is a useful tool for the assessment of the improvement and worsening of anxiety during and after combined therapy and only with drugs.

INDIVIDUAL AND GROUP CBT, CORRELATION OF LEVEL OF FUNCTIONING WITH LEVEL OF ANXIETY, DEPRESSION AND HOPELESSNESS

INSTITUTIONS
1. University Clinical Center, Psychiatric Clinic, Bosnia and Herzegovina
2. Department of Neuropsychiatry of Primary Health Centre Tuzla, Bosnia and Herzegovina

AUTHORS
1. Jasna Petkovic
2. Emir Tupkovic

Aims: We analyzed 30 of patients with symptoms of anxiety, depressive and hopelessness, treated with group therapy only (group I), individual therapy only (group II), or combined individual and group cognitive-behavioral therapies (CBT) (group III).

Methods: For 18 months there have been used Beck Depression Inventory (BDI), Beck Anxiety Inventory (BAI), Beck Hopelessness Scale (BHS) and Global Assessment of Functioning (GAF) on the beginning, at the end of treatment, and 6 months after treatment.

Results: Average values at the beginning of therapy in group I were: BDI 51.2 ± 9.8, BAI 46.5 ± 14.9, BHS 11.5 ± 7.4, GAF 49.7 ± 9.2; in group II: BDI 40.6 ± 15.6, BAI 43.3 ± 14.6, BHS 6.8 ± 8.0, GAF 48.8 ± 9.7; in group III: BDI 35.2 ± 11.7, BAI 35.8 ± 10.3, BHS 5.3 ± 5.3, GAF 50.5 ± 7.9. After 12 months improvements were observed. After 6 months without therapy worsening was observed. In group I through all stages BDI showed significant correlations with GAF: -0.56 before CBT, -0.52 after CBT, and -0.52 after six months without therapy

Conclusion: Combination group and individual CBT increasing global level functioning in comparison only with group CBT or individual CBT.

Therapeutic Drug Monitoring (TDM) data regarding recommended therapeutic ranges of serum concentrations of psychotropic medications are often obtained from samples of highly selected individuals, who may not be representative for the average psychiatric patient in everyday clinical practice. Therefore studies under naturalistic conditions are important to clarify the full clinical relevance of TDM. During a 12-month period all TDM-analyses of the tricyclic anti-depressants amitriptyline and clomipramine in an unselected sample of depressive inpatients were retrospectively evaluated to examine the relationship between serum levels and clinical response as well as adverse effects.

In patients with amitriptyline, the mean serum level in responders was significantly higher than in non-responders and was even slightly above the recommended therapeutic range. In patients receiving clomipramine, responders as well as non-responders had a mean serum level above the recommended range with responders showing a slightly lower level closer to the upper limit of the therapeutic range. Patients with adverse effects had higher serum levels than patients without adverse effects in both medication groups, although only in the clomipramine group this difference reached significance.

Our results suggest that therapeutic ranges in naturalistic settings may in some ways differ from those obtained in study settings. In severely ill depressive inpatients a serum level near or even slightly above the upper limit of the recommended therapeutic range may be necessary to reach an adequate clinical response.

Schizophrenia remains a severe disorder that is associated with a poor outcome in a large subgroup of patients. Major efforts should be made to improve treatment especially in the long-term psychopharmacotherapy. Twelve patients suffering from schizophrenia were on the posthospital treatment with the Long Acting Risperidone (LAR). We followed their clinical improvement by CGI scale. Also we followed therapeutically compliance of the patients, meaning their satisfaction with the therapy and regular coming on the two-week controls. The study lasted for six months. Results: 12 patients, 9 male, 3 female, mean age 32.5 years. We found out the significant improvement at 83.3% of the patients, measured by the CGI scale. The majority of patients - 58.3%- were given LAR 50 mg on two weeks, than 37.5 mg LAR for 16.6% of the patients, and 25% of patients with 25mg LAR. LAR has been shown a very high percent of therapeutically compliance, meaning subjective satisfaction with the therapy, and regular coming for the two-week controls, when they were receiving the injection of LAR. Such compliance was reported by the 75% of the patients. Only two patients (16.6%) relapsed during the study. These results encourage us to believe that many more patients will benefit from the advantages of the second generation of long acting preparations, which LAR is.

USE OF CLOZAPINE IN ACUTE MANIA

INSTITUTIONS
1. Spandana private psychiatric hospital, psychiatry, Mangalore, India

AUTHORS
1. Madhava Kalya Srinivas Rao¹, Dr, MD, drmadhava_rao@yahoo.com

‘Clozapine’ a globally well known molecule for schizophrenia (more so, for refractory/ resistant) was used by author Dr. K.S Madhava Rao (formerly H.O.D, Psychiatry, Wenlock medical college hospital) and Dr. Ravish Thunga, now Prof and H.O.D, Kasturba Medical College, Mangalore. Way back in 1995. It was given to 20 patients (pilot study) of ‘acute manic excitement’ for 7-12 days along with Lithium Carbonate/sodalproate. Tab Lorazepam at night if need be was used S.O.S to control excitement and avoided use of any injectable neuroleptics including Haloperidol (WHICH OFTEN CAUSED DISTRESSING EXTRA PYRAMIDAL SIDE EFFECTS) Encouraging results were presented at ANCIPS Jan 1996 (Annual National Conference of Indian Psychiatric Society) at Bangalore, India.

Since then the use of ‘clozapine’ 50-200 mg/day was continued on more than 200 patients so far between age group of 16 to 64 yrs with excellent result as regard to control of excitement/agression till mood stabilizer like Lithium/ Sodium Valporate take over and totally avoiding inj. haloperidol which causes distressing akathjea, EPS and not cost effective. Detailed results to be depicted on poster.

Therapeutic factors in group psychotherapy could result with symptomatic, behavioral and personality changes. According to Yalom (1985) therapeutic factors are: instillation of hope, universality, imparting of information, altruism, the corrective recapitulation of the primary family group, development of socializing techniques, imitative behavior, interpersonal input, interpersonal output, group cohesiveness, catharsis and existential factors.

In this study we will compare the results of therapeutic factors by Yalom’s questionnaire in the psychodynamic inpatient and day hospital group psychotherapy.

Objectives: Psychosocial rehabilitation addresses issues like low-self esteem, low motivation, social isolation, promoting social inclusion, supporting people in productive and meaningful lives within the community and, ultimately improvement of their general outcome. The authors review data concerning all admissions on the Psychosocial Rehabilitation Service (PRS) in Hospital Magalhães Lemos (Oporto, Portugal) and considered their impact on two outcome domains (number of admissions and hospital days used). Methods: This retrospective cohort study assessed socio-demographic and clinical characteristics of patients treated inPRS between September 1989 and December 1996. The outcome measures were both the number of inpatient admissions and the length of stay before and after their first admission in the PRS. Statistical analysis was carried out by NCSS 2000. Results: Our sample included 592 subjects (53% male; 47% female), mostly unmarried (69%), with mean age of 39 years old. The most prevalent diagnosis was psychotic disorder (47%), with a 73% male predominance. The second most prevalent diagnosis was depression (22%), followed by neurosis (17%) and personality disorders (8%). The results showed reduction in the number of psychiatric admissions per year (p<0.000) and in the length of stay (p<0.000), after beginning treatment in the PRS. There were also statistical differences when analyzing different diagnosis separately, with the greatest effect in the subgroup of psychotic disorder. Conclusion: We conclude that PRS intervention improves the effectiveness of mental health services, reducing psychiatric admissions and the total number of hospital days.

4. Raul Fernández-villamor Ortiz1, Dr.
5. Carolina Parra Gonzalez1, Mrs.

OBJECTIVE: Cognitive dysfunction constitutes a fundamental feature of schizophrenia. The objective of our study was to evaluate the cognitive enhancing effects of ziprasidone in patients with schizophrenia.

METHODS: This was a prospective, observational, non-comparative, 12-month follow-up study conducted under conditions of usual clinical practice. 30 patients with schizophrenia according to DSM-IV-TR criteria were switched to ziprasidone from their previous antipsychotic medication because of sub-optimal efficacy or intolerability. Efficacy variables included change from baseline in scores on cognitive tests of attention/vigilance, learning/memory, executive function, and verbal fluency. The following cognitive tests were performed at baseline, month 3, month 6 and month 12 (study endpoint): FCSRT - Free and Cued Selective Recall Test-, SDMT -Symbol Digit Modalities Test-, COWAT, Stroop y BPT-Brown-Peterson Task Efficacy was assessed in all patients who had received at least one dose of study medication, and had at least one post-baseline cognitive assessment (26). The significance of changes versus baseline in scores on the different cognitive tests at the study endpoint was calculated using Student’s t test.

RESULTS: Significant improvements were seen at endpoint in all cognitive assessments. After 12 month of treatment with ziprasidone the mean change (SD) in the tests score was: FCSRT Free 0.7(0.8) p=0.0005, Cued 0.5(0.8) p=0.0079; SDMT Total-Mistakes 3.2(4.9) p=0.0025; COWAT P-words 2.1(2.2) p<0.0001 animals 1.9(2.7) p=0.0013; STROOP 3.9(4.9) p=0.0004; BPT 0.5(0.4) p<0.0001.

CONCLUSIONS: These data suggest that ziprasidone has cognitive benefits. Patients requiring a change in antipsychotic therapy may exhibit cognitive improvement following a switch to ziprasidone.

4. Sayeed Akhtar4, Dr, MD DNB

Background: The prevalence of cardiovascular and metabolic comorbidity in schizophrenia is a significant public health concern, but comparative data with a normal population is rarely available. This adverse effect has been described with several antipsychotics to range between 20%-60%, at least double the prevalence in the general population.

Aims: To investigate the prevalence of metabolic and cardiovascular risk in people with first episode schizophrenia treated with antipsychotics compared to a normal matched population from the community.

Methods: Case-control prospective study of 99 people treated with antipsychotics in a tertiary care hospital and 51 age- and gender-matched controls. All consecutive patients with first episode schizophrenia at our referral psychiatric hospital were recruited in an extensive prospective randomized, double-blind controlled study which included measures of triglyceride (TGL), high-density lipoproteins (HDL), cholesterol (CHL) and very low density lipoproteins (VLDL) levels and randomized to receive either, haloperidol, olanzapine or risperidone. The prevalence of 10-year cardiovascular risk and metabolic profile changes were calculated and compared with the matched general population.

Results and Conclusion: As this is an ongoing study, the results and conclusion will be the focus of presentation at the conference.

Electroconvulsive Therapy (ECT) is a safe and efficient method used in the treatment of several psychiatric pathologies that has been available for more than 60 years. Despite the advances in psychopharmacology refractory psychiatric illness is still common. As so ECT continues to be one of the available therapeutic alternatives, indicated in the treatment of major depression, schizophrenia and mania, among others. In clinical practice ECT use is variable, not only in different countries, but also between different departments of the same psychiatric institution.

Objectives: Socio-demographic and nosologic study in a population of patients of the Magalhães Lemos Hospital submitted to ECT throughout a period of 24 months. Materials and Methods: Data was collected by reviewing the clinical records of the patients submitted to ECT between January 2006 and December 2007. The collected data was statistically analyzed with the program Epi-Info, in order to obtain descriptive parameters. Results: In a sample of 57 patients it was verified that there isn’t a significant predominance of gender, the average age is 48 years, the average number of sessions is 9, and the technique was mainly bilateral. The main indication is Schizophrenia, followed by Major Depression.

Conclusions: The obtained results match the primary indications for ECT usage. The need for long-term follow-up studies of these patients is required.

The effects of group occupational therapy on patients with schizophrenia have been empirically observed. However, there have been only a few studies that confirmed its effects with consideration for group characteristics. Therefore, we performed 3 structurally different programs of group occupational therapy and evaluated differences in effects among these programs.

Inpatients with schizophrenia in a psychiatric hospital were allocated into 3 groups: a parallel group performing multiple types of activity, parallel group performing 1 type of activity, and cooperative group performing 1 type of activity. During the 3-month occupational therapy period, each program (2 hours) was performed once a week 12 times. For the measurement of effects, the Assessment of Communication and Interaction Skills (ACIS) and Assessment of Motor and Process Skills (AMPS) were used. The results of these assessments and general information were comprehensively evaluated. This study was approved by the ethical committee of our institution, and informed consent was obtained from all participants.

Twenty-five patients who fully participated in the program to its end were evaluated as the subjects. The ACIS and AMPS scores changed in the 3 groups, and these changes markedly differed among them. In particular, the cooperative group who performed 1 type of activity showed improvement in many items of the ACIS and AMPS.

Our results showed differences in the effects of group occupational therapy in patients with schizophrenia. To perform effective occupational therapy based on group characteristics, its effects should be further evaluated from other aspects.

Objective: Schizophrenia is chronic disease characterized by bizarre delusions and hallucinations, but social, occupational functioning and quality of life depend from cognitive symptoms. The aim of our study was to evaluate whether existing antipsychotics can improve cognitive performance.

Methods: A total of 100 female inpatients, mean age 41 years, with schizophrenia, have been followed for twelve months, were randomly assigned to receive either atypical antipsychotics/risperidone, olanzapine, clozapine, quetiapine, amisulpride/or their various combination. The main instruments used were the structured interview according to ICD-10 and DSM IV, PANSS, CGI and battery of neuropsychological test. Evaluation was made at enrollment and 3,6 and 12 months of treatment.

Results: All patients completed study, mentioned drugs demonstrated some degree of improvement in various areas of cognitive performance but in most cases mild to moderate. The best effect on cognitive domains showed combination therapy clozapine/amisulpride in median doses, afterwards clozapine/quetiapine and clozapine/risperidone.

Conclusion: Neurocognitive deficits are a core feature of schizophrenia. New generation antipsychotics may improve and reduce these deficits. In our study better result in improvement cognitive function such as attention, memory, executive function, showed combination therapy especially clozapine/amisulpride, then clozapine/quetiapine and clozapine/risperidone, although their effects were in most cases moderate, but in few significant. Anyway the reality is no mighty medication existing for neurocognitive deficits in schizophrenia.

Although it is controversial that seizure duration can influence the efficacy of electroconvulsive therapy (ECT), a missed or brief seizure is considered less effective ECT. Of the background in the practice of ECT, hyperventilation may augment the seizure duration. In order to elucidate these hypotheses, we performed double-blind randomized controlled trial for nineteen patients. They were divided into two groups, according to the end-tidal pressure of carbon dioxide (ETCO₂): the moderate hyperventilation group with ETCO₂ of 30mmHg and the normal ventilation group with ETCO₂ of 40mmHg. ECT was performed under general anesthesia with propofol and suxamethonium. During ECT electroencephalogram (EEG) and electromyogram (EMG) were recorded. The Global Assessment of Functioning (GAF) score were also analyzed prior and following six sequential ECT. The moderate hyperventilation group showed a significant increase in EEG seizure duration in the first treatment compared with the normal ventilation group (p<0.05). However, EEG seizure duration in the subsequent treatments and EMG seizure duration in all the treatments did not differ between two groups. The moderate hyperventilation did not prevent the increase in seizure threshold or shortening of seizure duration. No complications or severe adverse effects were observed after ECT in any of the six treatments. The GAF score were not significantly changed with moderate hyperventilation. We conclude that moderate hyperventilation is safe and may be useful for seizure augmentation prior to the re-stimulation with higher intensities.

OLANZAPINE INDUCED PANIC ATTACKS IN BIPOLAR DISORDER

INSTITUTIONS
1. Ankara University, Turkey
2. Institute of Psychiatry, KCL, United Kingdom

AUTHORS
1. Berker Duman¹
2. Ceren Goker¹
3. Frederique Van Den Eynde²
4. Vesile Senturk¹

Olanzapine was recently registered as monotherapy in the long-term treatment of bipolar disorder (FDA, 2004). Therefore, in bipolar disorder, information about side-effects other than metabolic problems remains rather limited. To our knowledge, there are no previous reports on olanzapine induced panic attacks in bipolar disorder. We describe here such a case. S. is a 22 year old college female student who presented with elevated mood, grandiosity, insomnia, persecutory delusions and auditory hallucinations. These symptoms had gradually increased in a period of 10 days. As a consequence, she was hospitalised for a manic episode. Olanzapine was started and the dose was increased to 20mg/day. Soon after, she developed tachycardia, an intense fear to die and agoraphobia. Her mood symptoms were well controlled after 3 weeks and she was discharged with no residual manic symptoms. However, after discharge, she had several emergency admissions for panic attacks. Eventually, she was readmitted with the diagnosis bipolar disorder I with psychotic features in remission, though with an anxiety disorder with panic attacks due to a substance use according to SCID-I assessment. BPRS, HAM-D, YMRS, UPDRS-ME scores were 34, 17, 6 and 4 respectively. In addition, her BMI had increased from 21.33 to 26.66 kg/m² and laboratory measures showed impaired liver parameters.

Conclusion: This is the first case report on olanzapine induced panic attacks in bipolar disorder. Previously, two similar cases were reported in schizophrenia. We would like to draw attention to this potential side-effect of olanzapine in bipolar disorder.

5. Carina C D’Alicante¹, Ms, chaubetca@gmail.com
6. Euripedes C Miguel¹, Mr, PhD, ecmiguel@usp.br

Obsessive compulsive-disorder (OCD) patients present compliance rates near 80% in clinical trials. However, this rate may not reflect what happens in naturalistic settings due to the strict inclusion criteria used in clinical research and to the methods to avoid drop-outs developed for research purposes that are not replicated in naturalistic settings. The objective of this study was to evaluate rates of non-compliance in a naturalistic clinical setting and the effectiveness of simple measures to avoid drop-outs due to treatment abandonment.

Methods: The rates of non-compliance among patients included in an OCD treatment program with broad inclusion criteria were evaluated. In the first year no measures for drop-out prevention were used. In the second year reduction of consultation intervals and telephone confirmation before consultations were implemented. Chi square test was used to compare frequency of treatment discontnuation between time frames and groups of treatment.

Results: Two hundred fifty four patients were included in the treatment program during the two year period. The total rate of treatment non-compliance in the two year period was 25.3% of the sample that initiated treatment. After the introduction of specific measures to enhance compliance, a significant reduction was observed in the second year when compared to the first in the group that received group cognitive-behavior psychotherapy (from 28% to 15.9%).

Conclusion: Naturalistic settings may present higher rates of discontinuation than clinical trials but simple measures to prevent discontinuation may improve these rates and make them similar to what is observed in clinical research.

2. Olusegun O Baiyewu\(^{2}\), Dr., MD
3. Mohammed H Ahmed\(^{1}\), Dr., MD
4. Victor O Olisah\(^{1}\), Dr, MD

Aims/Objectives: To determine the pattern of antipsychotic medication use and factors that may affect adherence among middle aged patients attending psychiatry clinics of Ahmadu Bello University Teaching Hospital (ABUTH), Kaduna.

Methods: 160 patients with psychotic symptoms, aged above 45 years were admitted into the study. Socio-demographic questionnaire containing information on medication was administered. BPRS was used to elicit presence of psychotic symptoms; AIMS and SCAN were used for abnormal involuntary movements and generate ICD-10 diagnosis respectively.

Results: Subjects were between 45-65 years, 70% were married, 61% were female; mean duration of illness was 21±7.5yrs while mean age at onset of illness was 27±10.2yrs. Only 25% of subjects had contact with mental health facility within two weeks of onset of illness, 59% were diagnosed schizophrenia, 96% had combination anti-psychotic medication, Chlorpromazine was most frequently used drug (55%), and unwanted effect of medication was common, only 1.3% had significant Tardive dyskinesia. Adherence was poor and relapse was high. Main reason for poor adherence was lack of insight.

Conclusion: Neuroleptic medication was the mainstay, polypharmacy and use of benhexol was rampant, adherence was poor, extrapyramidal side effects were common but Tardive dyskinesia was uncommon. Poor adherence may be responsible for the low incidence of Tardive dyskinesia and lack of insight was responsible for poor adherence.

PLASMA HOMOCYSTEINE LEVELS IN PATIENTS WITH SEVERE MAJOR DEPRESSION UNDERGOING ELECTROCONVULSIVE THERAPY - A SHORT-TERM Longitudinal STUDY

INSTITUTIONS
1. University of Erlangen-Nuremberg, Psychiatry and Psychotherapy, Erlangen, Germany

AUTHORS
1. Patricia Schütz\(^{1}\), Dr., MD, patricia.schuetz@uk-erlangen.de, 2. Helge Frieling\(^{1}\), Dr., MD, helge.frieling@uk-erlangen.de
3. Maike Peters\(^{1}\), Mrs, maike.peters@gmx.net, 4. Stefan Bleich\(^{1}\), Dr., MD, stefan.bleich@uk-erlangen.de,
5. Wolfgang Sperling\(^{1}\), Dr, MD, wolfgang.sperling@uk-erlangen.de

OBJECTIVE: Since major depressive disorders has been linked to elevated plasma homocysteine levels (Bjelland et al. 2003) this study was performed to determine whether homocysteine levels are changed before, during, and after ECT. 

METHODS: This short-term longitudinal study was designed as previously described (Agelink et al. 2001) with slight modifications. In brief, a total of 132 serial measurements of plasma homocysteine concentrations were performed on 11 patients suffering from severe major depression meeting DSM-IV criteria during the course of a unilaterally stimulated ECT series. Depressive symptoms were assessed by psychometric testing (Montgomery-Asberg-Depression-scale, MADRS) carried out on the day before the start of the first ECT and 24 hours post first ECT and as well as on the days after the fourth, seventh, and last (tenth) ECT. Pre-ECT and post-ECT (drawn after 1 and 24 hours) concentrations of plasma homocysteine were compared by multiple testing and paired t-test.

RESULTS: On average, 10.5 (SD 3.4) (range 7-14) ECTs were applied. As expected, MADRS scores reduced significantly (t-test, T=2.7, p=0.031) during ECT (baseline score from 1\(^{st}\) to 10\(^{th}\) ECT) from 32.0 (SD 9.0) to 19.1 (SD 9.4). At no point during the ECT series there was a significant increase (p=0.38) in the average plasma homocysteine concentrations. The maximal measured pre-ECT (baseline 1\(^{st}\) ECT) value of homocysteine was 13.2 µmol/L (SD 4.4) and 12.4 µmol/L (SD 3.1) after the 10\(^{th}\) ECT.

CONCLUSION: Homocysteine might not play a pathophysiologic role during ECT treatment response in patients with severe major depressive disorders.

AUTHORS

Aims
Despite data from receptor occupancy studies which support the use of lower antipsychotic doses in schizophrenia, there is scant data documenting such dosing patterns in clinical practice. We aimed to examine the frequency of low dose (defined as mean CPZ mg equivalent doses equal to or below 300) antipsychotic prescriptions in schizophrenia and their clinical correlates in the context of a comparison between studies in 2001 and 2004 within six East Asian countries.

Methods
Low dose antipsychotic prescription for a sample of 2136 patients with schizophrenia from six countries and territories (mainland China, Hong Kong, Korea, Japan, Taiwan, Singapore) were evaluated in 2004 and compared with data obtained for 2399 patients in 2001.

Results
Overall, the comparison between 2001 and 2004 showed a significant increase in low dose antipsychotic use from 24.8% to 44.0%. Patients who received low dose antipsychotics were significantly associated with older age, female gender, first admissions, less hallucinations and less disorganized speech. Multivariate regression analyses revealed that prescription of low dose antipsychotics was predicted by older age, first admissions, time period of study, less use of first generation, second generation and depot antipsychotics as well as antipsychotic polytherapy.

Conclusion
Low antipsychotic dosing is not uncommonly prescribed in East Asia. Its association with demographic, clinical and treatment characteristics may denote a group of patients who do not require higher antipsychotic dosing and can benefit from minimal effective antipsychotic dosing in the management of their psychotic illness.

AUTHORS
1. Carina Nelli Spelta¹, Dr, cspelta@hotmail.com

In addition to their therapeutic effects, interferon (IFN) commonly cause various side effects. The symptoms of depression induced by IFN therapy are common and can limit the treatment utility, often necessitating discontinuation of IFN therapy of the use of psychotherapeutic agents. The literature has reported effectiveness in the use of antidepressants for IFN-induced depression. We reported on a 49-year-old-man who never had suffered from a psychiatric disorder. Diagnoses were made according to DSM-IV criteria, and the severity of depressive symptoms was determined by the Hamilton Depressive Rating Scale score (HDRSS). Duloxetine appeared to be effective in the treatment of symptoms of major depression induced by IFN.

5. Zeljka Kosutic¹, Dr.

This project is meant for psychiatric patients of Special Psychiatric Hospital „Dr Laza Lazarevic” and it scopes various activities with same aim and the same purpose - preparation and realization of adapted theatre plays.

The primary (direct) goal of this project is to repulse and restrict sequences of disease, to reestablish capabilities which have been lost due to illness or to keep those ones which are endangered (tercial prevention), and all that by learning basic life skills that they are lacking.

The secondary (indirect) goal is better integration into more educated society (with more tolerance, less prejudices). Changes that we want to make are provoked thought drama/theatre expression, by which we have double gain: individual (fulfilling life experience and developing creative potentials of individual, which achieves psychological-therapeutic benefit) and social (due to it is a public play, it consider audience which is observing and learning, realizing, reconsidering and changing existing attitude, and therefore decrease prejudice and stigmatization). The positive changes that are noted: better structure of patients free time; control and development of basic life skills (communication skills, constructive conflict solving, stress control, social anxiety reduction); independence and active attitude, in opposite to passive acceptances of illness, with emphasis of healthy parts of personality; development of self esteem and self acceptance with illness - with things that they can and can not do. Indirectly there is also economy gain in sense of shortening hospital treatment, rationalization of sick leave and raising of general life surrounding and working ability.

MAINTENANCE ECT FOR TREATMENT-RESISTANT CATATONIC SCHIZOPHRENIA

INSTITUTIONS
1. Hospital Magalhaes Lemos, Departamento de Psiquiatria, Porto, Portugal

AUTHORS
1. Pedro Teixeira¹, Dr, MD, jpnovaisc@yahoo.com
2. Isabel Saavedra¹, Dr, MD, jpnovaisc@yahoo.com

There is controversy regarding the proper place of Electroconvulsi-vetherapy (ECT) in the management of the schizophrenic patient, especially in the context of the medication-resistant schizophrenia, given the NICE restrictions in 2003. The authors briefly summarize the recovery of a treatment-refractory catatonic schizophrenic patient. After the administration of maintenance ECT (M-ECT), during a 3-year period, combined with neuroleptic medication, the PANNS score reduced 37% (129 to 82). The majority of the proposed criteria for remission of schizophrenia (Andreasen et al, 2005) scored ≤3 (only two: N4 and N6, social withdrawal and lack of spontaneity, scored 4). The combined treatment is frequently associated with better outcome than either treatment alone and also improves quality of life and functioning in the long term. We conclude that it seems to be needed future systematic research into the practice of ECT for schizophrenia.

Aims/Objectives: To evaluate the bioequivalence, safety and tolerability of long-acting risperidone (LAI) injected into the deltoid muscle (DM) of the upper arm compared with the gluteal muscle (GM) of the buttock.

Methods: Adult patients with stable, chronic schizophrenia were eligible. Study 1 (n=170): randomized, open-label, single-dose, two-way crossover study; risperidone LAI was administered into GM (Panel I: 25 mg; Panel II: 50 mg) and DM (Panel I: 37.5 mg; Panel II: 50 mg) and separated by 85-day washout period. Study 2 (n=53): open-label, multiple-dose study, 4 sequential DM injections of risperidone LAI (37.5 or 50 mg) at 2-week intervals. A 21 gauge (1 inch) needle for DM injection and 20 gauge (2 inch) needle for GM injection were used.

Results: GM and DM administration of risperidone LAI were bioequivalent with respect to peak and total plasma exposure and exhibited dose-proportional pharmacokinetics independent of injection site. Median time-to-peak concentrations and terminal half-lives of active antipsychotic fraction were ~30 days with a terminal half-life of 6-8 days. Both administration routes demonstrated a similar tolerability profile including low rates of injection-site pain and reactions. For both trials the majority of these reactions were mild and of limited duration. No patients withdrew due to reasons related to the injection site.

Conclusion: Administration of risperidone LAI into the DM is bioequivalent to GM injection with a similar safety and tolerability profile to that of GM injection. Deltoid administration of risperidone LAI thus provides an additional choice for both physicians and patients.

QUETIAPINE IN THE TREATMENT OF PSYCHOSIS IN JUVENILE PARKINSON’S DISEASE: A CASE REPORT

INSTITUTIONS
1. Bakirkoy Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, 1st Psychiatry Department, Istanbul, Turkey

AUTHORS
1. Nesrin B’Tomruk¹, Dr, MD, tomrukn@superonline.com
2. Esra Sezgin¹, Dr, MD
3. Nihat Alpay¹, Dr, MD

Objective: Parkinson’s disease (PD) usually has an onset in later years of life, and has a progressive and chronic course. There are also early-onset and juvenile (JP) types. Motor fluctuations and dyskinesias occur earlier and the incidence of dementia is lower in JP. Psychiatric symptoms such as depression and psychosis are also prevalent. There is a high incidence of positive family history in early-onset PD. This case report aims to emphasize psychiatric comorbidity in PD and address treatment challenges.

Method: A case with JP & psychosis, and the course of the treatment is discussed.

Results: 42 year old female JP patient, in whom PD had developed at age 17. Her two sisters also had early onset PD. The patient was under antiparkinsonian treatment for 25 years and the psychosis developed in the last two years. The neurologic examination revealed bradykinesia, hypophonia, dysarthria, rigidity, bradykinesia and postural instability. Besides levodopa 312.5 mg tid, the patient was treated with quetiapine 400 mg bid and PD’s motor symptoms and psychosis improved considerably.

Conclusions: Treatment with dopaminergic agents in PD may induce psychotic symptoms. In managing this, decreasing levodopa dosage might not be tolerated and PD symptoms could exacerbate (1). Clozapine and quetiapine seem to be better treatment options in such cases (2).

EFFECTIVENESS OF LONG-ACTING INJECTABLE RISPERIDONE IN PATIENTS WITH SCHIZOPHRENIA AND SCHIZOAFFECTIVE DISORDER

INSTITUTIONS
1. Alex.Obregia: Psychiatry Hospital, Unit 7, Bucharest, Romania

AUTHORS
1. Silvia Trandafir, Dr., MD, Ph.D, silviatrandafir2004@yahoo.com

Objective: Relapses in psychotic disorders are mostly due to patients' inadherence to daily antipsychotic medication. This adherence is significantly improved when using long-acting medication. This study aims at proving the efficacy of long-acting risperidone.

Methods: Prospective, open-label, Patient ages 20-45 years old were administered long-acting risperidone, dosage 25 mg, 37.5 mg, and 50 mg every 2 weeks, for 6 months. Patients were assessed (BPRS, GAF, CGI, SF-36) before being included into the study group and 6 months after.

Results: 72% of the patients were diagnosed with paranoid schizophrenia, 8% were delirious disorder, 12% were diagnosed as residual schizophrenia, and 8% were schizoaffective disorder. Reasons for study inclusion were: inadherence to treatment (65% of the patients), unresponsiveness to previous antipsychotic treatments (20%), other reasons (25%) at baseline 60% of patients were assessed by CGI as severely ill, 38% were moderately and 2% were borderline. CGI- severity of illness improved significantly. GAF score improved from 10 to 29 in 12% of patients, from 30 to 59 in 76% and from 60 to 90 in 12%. SF-36 significantly improved during the 6 month period. BPRS scores were substantially improved with 20% in 60% of patients.

Conclusions: Efficacy was maintained after switching from orally administered to long acting risperidone. Switching was well tolerated.

8. Tamas Treuer, Dr., MD,PhD, treuer_tamas@lilly.com

OBJECTIVE: Poor adherence to antipsychotics is a major problem in long term treatment of schizophrenia, a relationship between poor adherence and relapse is well documented in the literature. One of the factors that may affect compliance is antipsychotic formulation. The primary objective of the study was to compare patient preference for olanzapine conventional tablet (OCT) with orodispersible tablet (ODT) as measured by a formulation preference question.

METHODS: A 12-week open label, randomized, crossover, multinational study (Turkey, Romania, Israel, Brazil, Mexico) conducted to estimate the proportion of patients preferring OCT over ODT after 6 weeks of treatment with each formulation. Outpatients with stable schizophrenia (CGI-S<4) on OCT monotherapy were randomized 1:1. Compliance, drug attitude were measured using DAI-10 and MAF scales; tolerability and safety by AMDP-5 questionnaire and adverse event summary.

RESULTS: From 263 randomized patients, 207 were eligible for the analysis and 175 patients answered the preference question. 106(61%) patients preferred ODT, and 48(27%) preferred OCT (p<0.001 adjusted for treatment sequence); 21(12%) expressed no preference. 90% of patients were rated as almost always compliant on both formulations. The adverse event profiles of ODT and OCT were similar: most common (>1%) adverse events were weight increase, hypertriglyceridaemia, and somnolence.

CONCLUSIONS: Most of the patients who answered the preference question declared to prefer olanzapine orodispersible to conventional formulation. Given the importance of patient's preference as one of the factors for future compliance, olanzapine orodispersible tablet could be a good choice.

EFFICACY OF TRAZODONE IN THE TREATMENT OF DEPRESSION IN ELDERLY PATIENTS

INSTITUTIONS
1. University Clinical Center "Zvezdara", Center of Psychiatry, Belgrade, Serbia and Montenegro

AUTHORS
1. Lela Trikos1, Dr., MD, lela_trikos@yahoo.com

OBJECTIVE: The aim was to investigate the efficacy of trazodone treatment of elderly patients suffering from depression.

METHODS: This study included 40 elderly outpatients with depression. Trazodone was administered over 6-week treatment period (150mg/day). The visits were organized at the beginning of treatment, after 2, 4 and 6 weeks. Efficacy of trazodone was measured by change in the Montgomery-Asberg Depression Rating Scale (MADRS) total score to each visit. Gathered data were statistically processed.

RESULTS: The mean MADRS total score decreased from 15.3 to 6.2. The percentage of patients in remission (MADRS total score = or < 12) was 78% by Week 6.

CONCLUSION: Trazodone was efficacious in reducing symptoms of depression over 6-week treatment of elderly patients.

5. Konstantinos Kontis1

Aims: The aim of the present announcement is to illustrate the evaluation of the process and the result of the implementation of a specific psychosocial rehabilitation program for chronic patients with major mental health problems and serious psychical impediments. This program -named 'Propolis'- is one out of eight main programs which are interconnected with the fourth acute Mental Health Unit of Psychiatric Hospital of Attica - Dafni, and is located in the centre of Athens. 'Propolis' consists of A: ten community nurses, psychiatrist, psychologist, social worker and other specialists (under part time status, i.e. instructor of psychical education, occupational therapist, e.c.t), B: eighteen clients, ten men and eight women with multiple psychosocial needs (the majority has been given the diagnosis of Schizophrenia and Personality Disorders), and C: specific principles, goals and practices which are based in eight functional axes, such us the psychological axis, psychiatric, social and cognitive skills axis, financial, community oriented axis and so on.

Methods: Data collection emerged from the study of the monthly evaluations which have been made by the specialists and the clients themselves, and include all the functional axes mentioned above.

Results: The illustration of the emerged material refers to six main integrated factors on a six time point continuum after an assimilating process (2001-2006).

4. Kenji Fukui¹, Dr., MD, PhD

The Meige’s syndrome is characterized by the presence of bilateral, symmetrical, dystonic cramp of face muscles or muscles of middle line of body. Both the etiology and the pathophysiology of Meige’s syndrome have been still uncertain.

Previous clinical observations and basic pharmacological studies have suggested that the disorders of basal ganglia function and neurotransmitters’ imbalance (dopamine and acetylcholine) can be with reason of pronouncement of symptoms presumably, and the dopaminergic receptors, especially of D1 type, play a crucial role in causing this condition. Based on these assumptions, dopaminergic receptor antagonists have been introduced as medical treatments. Several antipsychotics, however, have been reported as both therapeutic drugs and causes of dystonia.

Here, we report a case of a woman with idiopathic Meige’s syndrome whose dystonia improved with the use of aripiprazole, which is called a “Dopamine System Stabilizer”. Aripiprazole also has been reported as a cause of acute dystonia. In this case, however, it was effective as a treatment drug of Meige’s syndrome which should be concerned as another type of chronic (tardive) dystonia. This report suggests that aripiprazole might be useful in the treatment of chronic (tardive) dystonia including Meige’s syndrome. We will give a study of the mechanisms of Meige’s syndrome, which can be closely related to the dopaminergic systems.

PLASMA LEVELS OF PALIPERIDONE IN A NATURALISTIC SETTING

INSTITUTIONS
1. EVK Gelsenkirchen, Dept. of Psychiatry, Psychotherapy and Psychosomatics, Gelsenkirchen, Germany
2. Hygiene-Institut des Ruhrgebiets, Gelsenkirchen, Germany

AUTHORS
1. Heiko Ullrich¹, Dr., MD, ullrich@evk-ge.de
2. Matthias Weber², Dr., MD
3. Ralf Kudling¹, Dr., MD
4. Eckhard Klieser¹, Prof. Dr., MD

Aims: Paliperidone is a new compound with a special extended release formulation, which was introduced in Germany in 2007. Aim of our examination was to search for a correlation between plasma-levels of the compound and efficacy and tolerability in a naturalistic setting.

Methods: Of all inpatients at the evangelical clinics in Gelsenkirchen with the diagnosis of a paranoid schizophrenia according to ICD-10, who received a pharmacological treatment with paliperidone in 2007, 21 patients (14 female/7 male, mean age 42 +/-14.7 years) underwent blood testing for paliperidone-plasma-concentration. Paliperidone / 9-hydroxyrisperidone was detected by a validated method using liquid chromatography/tandem mass spectrometry (LC/ESI-MS/MS) after protein precipitation and dilution. In the linear range of 2 - 200 µg/l (r = 0.9996) the LLOQ was 2 ng/ml and the inter-day-precision at 20 µg/l was 6.6%.

Results: Severity of illness before treatment was overall 4.4 with a range of 1.2 on the CGI. Treatment outcome was 2.3 with a range of 0.9 on the CGI. Side-effects were not observed. The mean paliperidone-dose was 7.7 (+/- 2.7) mg/day, 6 patients received 12 mg daily. Plasma-concentrations of paliperidone were 36.25 +/-20.13µg/l for all patients, 54.73 +/- 12.84µg/l for the 12-mg-group and 28.86 +/-17.76 µg/l for the 6-mg-group. The correlation between dose and plasma-concentration was 0.59, there were no correlations observed for severity of illness, outcome or side-effects.

Conclusions: In our sample, treatment with paliperidone was safe and effective. We could establish a dose-plasma-level-correlation in a naturalistic setting with a mean plasma concentration for 9-hydroxyrisperidone of 36.25 µg/l.

DELTOID ADMINISTRATION OF LONG-ACTING ANTIPSYCHOTICS: PHYSICIAN AND NURSE ATTITUDES

INSTITUTIONS
1. Janssen-Cilag, Roderveldlaan 1, Belgium
2. Janssen-Cilag, 5026 RH Tilburg, The Netherlands
3. Janssen-Cilag EMEA, 2340 Beersel, Belgium

AUTHORS
1. P Geerts
2. S Bloem
3. A Van Bulck

Aims: Adherence to medication in schizophrenia is a challenge, which may be addressed through assured delivery of antipsychotic medication. Research was carried out to assess the attitudes of psychiatry healthcare professionals (HCPs) towards different administration routes and injection sites.

Methods: Pan-European HCP recruitment was conducted by telephone and the survey carried out on-line. Using conjoint analyses (multivariate statistical technique analysing preferences on the basis of combinations of different levels on various attributes), HCP’s attitudes to oral versus long-acting injectable antipsychotic medication and long-acting medication in gluteal versus deltoid routes were assessed. Research was carried out by Research International on behalf of Janssen-Cilag.

Results: 891 HCPs were surveyed (78% physicians/specialists; 22% nurses). 75% of HCPs had over 8 years’ experience in psychiatry. From the oral versus long-acting analysis, 50% of respondents would be more likely to prescribe a long-acting agent if the choice of a deltoid in addition to a gluteal injection was available. HCPs believed that one third of patients would more readily accept a long-acting deltoid injection in preference to the oral formulation. From the long-acting versus long-acting prescribing decision analysis, 54% would be more likely to prescribe deltoid injections if the choice of deltoid in addition to gluteal was available. HCPs believed that 60% of patients would accept a deltoid injection in preference to gluteal administration.

Conclusion: For antipsychotic medication, choice of a deltoid administration route, in addition to gluteal, was seen favourably by European psychiatry HCPs and may encourage improved adherence through increased prescription of long-acting medication.

COGNITIVE-BEHAVIOURAL THERAPY AND ANTIDEPRESSANT DRUG TREATMENT IN IRRITABLE BOWEL SYNDROME

INSTITUTIONS
1. Clinical Emergency central military hospital, psychiatry, Bucharest, Romania

AUTHORS
1. Daniel Vasile, DR., MD, PhD, danielvpsy@yahoo.com
2. Octavian Vasiliu, DR., MD
3. Diana Patriche, Mrs., MD
4. Paul Ivanov, Mr., MD
5. Beatrice Stanescu, Mr., MD

Objective: To quantify the effects of a combined psychotherapeutic and antidepressant program over the irritable bowel syndrome (IBS) evolution.

Methods: A group of 15 patients, 10 female and 5 male, mean age 42.5, with symptoms like chronic and frequent diarrhea or constipation, accompanied by pain, loss of appetite, abdominal fullness, anxiety and depressive features [1] were diagnosed with IBS. They were evaluated using Hamilton Rating Scale for Anxiety (HAMA), Hamilton Rating Scale for Depression (HAMD), Structured Clinical Interview for Axis I DSM-IV Disorders (SCID-I), every 4 weeks, for 6 months. All patients were included in a combined cognitive-behavioural therapy [2] and selective serotonin reuptake inhibitors (SSRIs) treatment.

Results: The symptoms in patients with IBS decreased under combined treatment from the first 4 weeks (-12.1 points on HAMA, -9.5 on HAMD) and this trend maintained throughout the 3 months and stabilised at a subclinical level after that. A large proportion of our patients presented associated clinical disorders at the admission (66.6%, n=10) - substance abuse (n=3), depression (n=3), anxiety disorders (n=3), posttraumatic stress disorder (n=1) but only a few (20%, n=3) remained with a psychiatric diagnosis after the 6 months of the study.

Conclusion: Combined CBT and antidepressant drugs therapy improves the prognosis of IBS patients because it decreases both associated psychiatric disorders and alleviates the specific IBS symptoms.

METABOLIC SYNDROME IN PSYCHOTIC PAIENTS TREATED WITH CLOZAPINE

INSTITUTIONS
1. Vincent van Gogh Institute for Psychiatry, Clinical Research, Venray, The Netherlands
2. Erasmus University Medical Centre, Psychiatry, Rotterdam, The Netherlands

AUTHORS
1. Paulien Steylen1, Mrs., MD, psteylen@vvgi.nl
2. Frank van der Heijden1, Mr., MD, PhD, fheijden@vvgi.nl
3. Hans Kok1, Mr., MD, hkok@vvgi.nl
4. Siegfried Tuinier1, Mr., MD, PhD, stuinier@vvgi.nl
5. Willem Verhoeven1, Mr., MD, PhD, wverhoeven@vvgi.nl

Aims/Objectives. The metabolic syndrome is an important risk factor for cardiovascular disease and diabetes mellitus. Treatment with atypical antipsychotics, particularly clozapine and olanzapine, is associated with individual components of the metabolic syndrome, like weight gain, dyslipidemia and hyperglycemia. The aim of the study was to assess the frequency of the metabolic syndrome in patients with psychotic disorders in an inpatient facility who were treated with clozapine for at least one year.

Methods. The presence of the metabolic syndrome was assessed according to the definitions of the World Health Organization 1999, National Cholesterol Education Program 2001 (ATP-III) and International Diabetes Federation 2005 (IDF). A total of 96 inpatients were treated with clozapine for at least one year, of which 73 were included.

Results. Patients (50 male; 23 female) were treated with clozapine for a mean duration of 9.6 years. Metabolic syndrome was found in 25% (WHO), 60% (ATP-III) and 66% (IDF) of the patients and was associated with female gender (p<.05). No association was found between the metabolic syndrome and duration of clozapine treatment. Frequencies of the individual components were 92% for dyslipidemia, 43% for obesity, 36% for hypertension, 18% for impaired fasting glucose and 18% for diabetes mellitus.

Conclusions. Metabolic syndrome is highly prevalent among patients with schizophrenia and other psychotic disorders treated with clozapine over at least one year. Regular monitoring and treatment of the possible health risks associated with the treatment of antipsychotic medication should therefore be part of routine clinical management in psychiatry.

TREATMENT OF DEMENTIA IN PARKINSON’S DISEASE BY NOOTROPIC DRUGS

INSTITUTIONS
1. Military Hospital, Neuropsychiatric Ward, Nis, Serbia and Montenegro
2. Special Psychiatric Hospital, Center of Forensic Psychiatry, Nis, Serbia and Montenegro

AUTHORS
1. Sibin D Vladejic1, Dr, MD, vladeic@bankerinter.net
2. Snezana S Vladejic2, Dr, MD, vladeic@bankerinter.net

Parkinson's disease represents the affection of extrapyramidal system, caused by degeneration of dopaminergic neurons of Substantia nigra and lack of dopamine in Corpus striatum. Dominant neurological symptoms are tremor, rigor, bradykinesia and postural instability. Most commonly found psychic symptoms refer to depression and dementia.

This study was conducted at neuropsychiatric ward of Military Hospital, Nis, during 2007. It included all patients diagnosed with Parkinson's disease, who also had symptoms of dementia caused by this disease. Cognitive impairment was treated by standardized remedy of Ginkgo biloba or selegilin. Assessment of cognitive functioning was made by MMSE scale. Patients were divided into groups according to their age (up to 60, and older than 60 years), basic therapy and degree of cognitive impairment at the base line. Follow-up period was one year.

Results of the study show that older patients, treated with levodopa, before therapy had mild to moderate cognitive impairment, regarding their ability of calculation, memory and orientation. Younger patients did not have cognitive impairment, or it was negligible. One-year follow up period shows that symptoms of cognitive deficit did not progress during the period of medication; both drugs showed same effects.

3. Serenella Fornari1, Dr., MD
4. Irene Netti1, Dr., MD
5. Pierluigi Ala1, Dr., MD
6. Claudio Mencacci1, Dr., MD

Aim: Incomplete adherence to oral treatment limits the effectiveness of antipsychotic treatment, requiring as a result the prescription of depot formulations. Long-acting risperidone (RLAI) is effective for short- and long-term treatment of psychotic disorders. Aim of this study was to evaluate the clinical response and tolerability of RLAI in the treatment of schizophrenic patients resistant or intolerant of conventional depot neuroleptics.

Methods: The study involved 30 outpatients, affected by schizophrenia (mean illness duration: 25 years ± 13.5 SD) who had been resistant to or intolerant of conventional neuroleptics. The patients were prescribed RLAI for 6 months at variable doses of 25-37.5-50 mg/2 weeks. Patients were switched directly from previous depot neuroleptics. Clinical outcome was assessed using PANSS, CGI, BPRS. All adverse events were recorded.

Results: Patients have been successfully switched from previous conventional depot neuroleptics without an oral supplementation. Early drop-out was observed on 36% of patients and a previous condition of intolerance of conventional depot neuroleptics was significantly correlated with discontinuation of RLAI treatment for adverse events (p<0.01). Most of the patients (64%) were maintained on 37.5 mg/2 weeks of RLAI throughout the treatment period. At study end, 45% of the patients met the criterion for clinical improvement (≥20% PANSS score reduction). BPRS and PANSS total scores showed a significant improvement over the length of the study (p<0.001).

Conclusions: RLAI was effective in patients with chronic schizophrenia who had been resistant to or intolerant of depot conventional neuroleptics. Discontinuation rate was higher for patients previously intolerant of conventional neuroleptics.

VICTIMS OF MOBBING-THERAPY AND REHABILITATION

INSTITUTIONS
1. KBC Dr Dragisa Misovic, Serbia and Montenegro

AUTHORS
1. Branko V Vukovic
2. Branka V Vukovic
3. Jasminka A Jankovic
4. Dusica Markovic

Beside the conventional victim we can recognize that mobbed is a victim too in some way and working place and environment is damaged. Men have organize tree types of therapy and rehabilitation:

Therapy and rehabilitation of conventional victim. Therapist is psychiatrist and psychotherapist, which use medical therapy, psychotherapy and social rehabilitation. Therapy and rehabilitation of working place Therapist is family systemic psychotherapist and social worker who correct relationships and communications between colleagues. Healthy and warm environment is not good ground for development of mobbing.

Therapy and rehabilitation of mobber. Therapist is psychiatrist, psychotherapist and social worker, which use different psychotherapy methods. Mobber is victim because he or she is victim of his/her impotency or weakness. They have serious psychological problem which requires therapy. Without this problem they wouldn't be aggressive and mobbed. They are usually leaders and have god-working qualifications and they have significant influence in business issue. Beside scourge they must go through process of therapy and rehabilitation. They will return to working place as better person so he or she will be able to work on better and healthy way.

THE MANIFESTATION OF “PARENTIFIED TYPE” OF SEXUAL OFFENDER IN GROUP THERAPY

INSTITUTIONS
1. National Tsing Hua University, Center for Teacher Education and Counseling Center, Hsinchu, Taiwan Republic of China

AUTHORS
1. Chia Yu Wu, Dr., PhD, wu_chia_yu@yahoo.com.tw

The researcher uses the method of group therapy to carry on 24 times therapeutic sessions to different types of sexual offenders. Among the sexual offenders members, the “parentified type” of sexual offenders display strongly changing motivations and participating willingness in the group screening session. During the group therapy sessions, they display actions of flattering the leader and difficulty in refusing other’s request. These interpersonal patterns which hope to receive commendations and affirmations from others caused the manifestation of “parentified” sexual offender in group therapy is extremely different to other type of sexual offenders.

Besides, the reason for this type of sexual offenders committing the crime is related to the pressure issue. However, high-risk situations that easily cause them to commit the crime includes: (1) when they are being looked down upon by others; (2) when they have tried but still can not succeed; and (3) when the situation got out of control.

In the leading process, if the group leaders can identify the interpersonal pattern of “parentified type” of sexual offenders, control the origin of the pressure and high-risk situations of committing crimes, also remind these members to avoid setting a high expectation of themselves and taking up too many responsibilities and pressures as these are important process of preventing committing crimes.

ASSOCIATION BETWEEN MEMANTINE AND GALANTAMINE AS A TREATMENT OF ADDITION FOR ALZHEIMER’S DISEASE

INSTITUTIONS
1. Hospital Italiano de La Plata, Psiquiatria, Argentina
2. Hospital Centenario, Argentina

AUTHORS
1. Julio C Zarra, Dr.
2. Luisa Schmidt

At the conclusion of this session, the participant should be able to demonstrate with use the association memantine - galantamine in neurocognitive disorder: Alzheimer’s disease, improve cognition, behavioural symptoms, and the general state recognized as neurocognitive disorder.

Objective: The efficacy, safety, and tolerability of nootropic cholinergic agent: GALANTAMINE (with a dual mechanism of action on the cholinergic a system) and moderate affinity NMDA- receptor antagonist: MEMANTINE, were assessed taking into account the profile of patients with neurocognitive disorder: Alzheimer’s disease, from the clinical aspects and the different classifications.

Methods: The experience included 188 patients who were enrolled in a prospective, observational, multicenter, and open-label study to receive 16 mg/day of galantamine and 30 mg/day of memantine for 12 months of treatment of addition.

Results: The therapeutic response was measured using the Mini Mental State Examination (MMSE), Clinical Dementia Rating (CDR), Alzheimer’s Disease Assessment Scale (ADAS-GOG) the Clinical Global Impression Scale (CGI) and the UKU scale of adverse effects taking into account the efficacy, safety and adverse events of the treatment.

Conclusion: The final results of the study showed that galantamine with addition memantine improves cognition, behavioural symptoms, and the general well-being of patients with cognitive impairment: Alzheimer’s disease. The incidence of adverse events was not significant and a very good profile of tolerability and safety was observed.

SURVEY ON EMOTIONAL AND BEHAVIORAL SYMPTOMS OF MIGRATION ALBANIAN CHILDREN

INSTITUTIONS
1. University Hospital Center Mother Teresa, Child and Adolescent Clinic of Psychiatry, Neurology Neurosurgery Psychiatry, Tirana, Albania

AUTHORS
1. Valbona Alikaj1, Mrs, MD, evag4@yahoo.com
2. Ariel Como1, Mr, MD
3. Sonila Tomori1, Mrs, MD

Aim The detection of children with difficulties in emotions, concentration, behavior, peer relations in a new rural area of Tirana.

Method Data were collected using SDQ that was completed by children of 10 to 14 years old as well as from their teachers. The number of completed interviews was 269. SDQ includes 25 items, generating scores for Conduct Problems, Inattention-Hyperactivity, Emotional Symptoms, Peer Problems, and Prosocial Behavior. The statistical analysis is completed using SPSS 10.0 for windows.

Results The samples’ mean age was 11.2 years. Approximately 19% of children had emotional and behavioral difficulties, 28% had peer relations problems. About 70% of these children had an impact on their functioning. Children that resulted with difficulties in emotions, concentration, behavior or peer relations varied by sex, age and socioeconomic status.

Conclusions It is the first research done on migration Albanian children which takes out data from a sensitive instrument used in many countries. These data show severe difficulties in emotional, concentration, behavior and peer relations in a significant number of Barthô’s school children. Mental health service is not available to these children with definite or severe difficulties. The study demonstrates a necessity of intervention in this rural Barthô’s area, by developing a mental health service for children and adolescents, supporting them to achieve their potential and become contributing members of Albanian society.

INTERACTIVE COMMUNICATION IN VERBAL AND NON-VERBAL AUTISTIC CHILDREN

INSTITUTIONS
1. School of Medicine University of Sao Paulo, PT, SLP and OT, Sao Paulo, Brazil

AUTHORS
1. Fernanda Dreux Fernandes1, Dr, PhD, fernandadreux@usp.br
2. Cibelle La Higuera Amato1, Dr, PhD, cibelle@amato.com.br

The interactive use of any form of communication is one of the critical aspects of the adaptation of children with autistic disorders. The subjects of this study were 20 autistic children (ages 2.10 to 10.6 y) divided in two groups, 10 verbal children and 10 non-verbal children, according to the psychiatry’s report. All subjects were video-recorded during 30 minutes sessions of play-interaction with their mothers and none of them had speech-language therapy prior to this research. Data were analyzed according to the aspects of number of communicative acts per minute, communicative functions and communicative means expressed.

Results show that in both groups the children occupy close to 40% of the communicative space, with more individual variation in the non-verbal group. The number of communicative acts expressed per minute show a clear difference between the groups, with the non-verbal children presenting far less communicative acts than verbal children. The analysis of the use of the different communicative means show that in both groups the gestual mean was the most frequent. Interactive communicative functions were absent in two on the verbal and in four of the non-verbal children. It may be concluded that the determination of the functional communicative profile conducted in this study confirmed this children's difficulties in the assessed areas and that these difficulties sometimes determine their performance. The largest individual variations in the non-verbal group demands other researches comparing different groups of subjects of the autistic spectrum.

2. Jabbar Haidari, Mr

An essential component of sound public policy is awareness of the prevalence of behavioral & emotional problems among children.

The aim of study was to determine the prevalence and elated factors of psychiatric disturbances, health problems and habits, among school 926 children of primary school children (in rural and urban schools) were selected by stratified randomized sampling. The Rutter’s parent and teacher scales were used. Teachers’ & parents, estimation of the prevalence rates were 24.9% & 15.9%. The most prevalent disorder was attention deficiency 13.3% & 11.1% and the lowest was Antisocial behavior 1.6% and 0.4%, on parent and teachers reports, respectively. Although the results showed 7.5%, 13.1% of the boys and 5.8%, 11.8% of the girls were deviant on parent and teacher reports, no significant differences found. There were significant relation between behavioral-emotional disturbance on the Rutter’s parent reports and somatic compliant ($\chi^2=16.40, df=2, p<0.001$), sleep problems ($\chi^2=12.74, df=4, p<0.001$), and with that children were abused by parents F<0.001.

Conclusion: The prevalence of emotional & behavioral problems among the school children was different from other countries according to type of psychiatric problems. As well as close cooperation between school teachers, parents and health care provider is essential to ensure physical and mental healthy development of children.

3. Asli Taşyir, Mrs.

Objective: Children with behavioral disorders give rise to psycho-social stressors for the parents (1,2). The purpose of this study was to examine the factors affecting coping strategies of the mothers of children with attention deficit and hyperactivity disorders.

Method: The study was carried out in the Department of Child Psychiatry, Ege University, between December 2006 and February 2007. The sample consisted of 107 mothers, selected by basic random sampling method. The data was collected by Introductory Information Form and The Coping Strategy Indicator (CSI) and analyzed by variance analysis and t test.

Results: The mean scores of CSI are as follows: problem solving 16.85 ± 4.06, seeking for social support 19.73 ± 4.73 and avoidance 14.41 ±2.57. It has been calculated that there is a significant difference between CSI mean scores of mothers and the age of the children, perception of the relationship with children and the family of the mothers (p<0.05).

Conclusion: Mothers utilize problem solving, seeking social support and avoidance approaches at low levels. Mothers use problem solving and emotion focused approaches together to cope with stress. Their coping strategies show significant differences with the age and relations with children and the family. This suggests that mothers are well informed to cope effectively with the problems.

3. Şafak Ergül, Dr., PhD, safak.ergul@ege.edu.tr
4. Leyla Özkan, Mrs.

Objective: This study was planned to investigation of education and effective factors on education about child abuse and neglect toward mothers.

Method: This semi-experimental study has been conducted with mothers of the children who were treated (n=50) in Turkey Izmir Dr. Behçet Uz Children Hospital between February 2006-April 2006. Data was collected by two forms. The first one was the descriptive form, the second one was the knowledge form which was to aim to respect of mothers’ knowledge about child abuse and neglect, developed by researchers in line with the related literature (1,2).

Results: The pre education point mean 19.20±2.32, the post education point mean 20.44±2.04 was found. This point difference was found statistically significant. While sociodemographic characteristics like age, marital status, income, working status, family structure were not found significantly, mothers’ having more than three children point difference was found statistical significant. Mothers’ point difference was not found significant according to history of violence from others, violence from husband and opinions of violence for education was not found significant. Mothers’ point difference was found significant according to get child without plan and status of couple relationship.

Conclusion: Education toward mothers about child abuse and neglect was found effective. Using education to different sociodemographic characteristics and the bigger sample with evaluation attitudes were advised.

3. Selcan Sunelcan, Mrs.

Objective: To have an autistic child presents many obstacles and responsibilities to the parents. This study was carried out to determine the factors that affect the quality of the life of the parents who have autistic children.

Method: The study was carried out in the 5 Special Education and Rehabilitation Centres located in Izmir, Turkey, between the dates December 2006 and February 2007. The research sample consisted of 126 parents. The data was collected by Introductory Information Form and WHOQOL-BREF Life Quality Scale (1,2). Percentage distribution, ANOVA and t test were used to analyze the data.

Results: There was a significant difference between children’s aggressive behavior tendencies and WHOQOL-BREF social field mean score of parents (t=−1.03, p<0.05).

Conclusion: According to these findings, it has been determined that the quality of the life of parents, who are bachelor and also whose children shows aggressive behavior, is to be lower in physical and social fields.

2. Ayşegül Bilge², Dr
3. Aysun Babacan Gümüş³, Dr

Aims/Objectives: A number of studies have identified the effects of end stage renal failure on growth and psychological state for children on dialysis. Contribute further to the understanding of psychosocial outcome of children and adolescent with end-stage renal disease.

Methods: The sample was consisted of 100 children, ages 11 to 18 years chronic renal failure and adolescent consecutively admitted to the Ege University Hospital Child Nephrology Department. Four instruments were used to explore the presence of probable depressive and alexithymia, social anxiety of the patients: Children’s Depression Inventory, Social Anxiety Scale for Children-revised, Toronto Alexithymia, Child Behaviour Checklist /4-18.

Results: In the research group there were 47 (54.7%) girls and 39 (45.3%) boys and their mean age was 15.03 ± 3.4 years. 81.4% child and adolescent were alexithymic (47.7%) or suspicious alexithymic (47.7 %). The mean Alexithymia scale score of the study group was 69.7±10.0. The depression scores were increased with alexithymic child and adolescent. There was positive correlations between depression and social anxiety in child and adolescent (p=0.004, r=0.390). The boys and the girls had significantly different scores on the problem behaviours subunits of the Youth Self Report; somatic complaints, anxious-depressed.

Conclusion: This study demonstrated that, the children and adolescent with chronic renal failure demonstrated more anxiety, and alexithymic problems. In addition to psychopharmacologic treatment, psychotherapeutic approaches should have an important place in the treatment of this disorder.

MENTAL DISORDERS OF CHILDREN AND ADOLESCENTS - THE VICTIMS OF SEXUAL ABUSE

INSTITUTIONS
1. The State Center of Social and Judicial Psychiatry of V.P. Serbsky, Moscow, Russian Federation

AUTHORS
1. Valentina Badmaeva¹, Dr., nasankaeva@mail.ru

The aim of investigation - is the determination of clinical and age features of mental disorders of children and adolescents - the victims of sexual abuse.

Materials and methods: 90 children and adolescents - the victims of sexual abuse were examined: 46 (51.11%) were the children till 14 years old and 44 (48.89%) were adolescents 14-18 years old. The mean age of the patients composed 13.2 years old.

Results. An investigation showed that in 84% of victims with sexual trauma the acute reactions on stress of various severity and duration were developed. In 36% there were shock and subshock reactions with distinctive structural and dynamic features and phase curren-
cy. Posttraumatic stress disorder was marked in 14% of adolescents, girls principally. The disorder had prolonged and undulate current with aggravation in consecutive and judicial situation. In 34% ado-
lescent age victims (female only) short depressive reaction with 1 month duration was developed: astheno-depressive, restless-depressive and dysphoria variants. Prolonged depressive reaction with 3-
6 months duration accompanied by the aggravation of the state in consecutive situation developed in 24% adolescent age females. 16% of the children of 9-13 years old had phobias and restless disorders. Mixed emotion and behaviour disorder with elevated irritability, irascibility, defiant behaviour with auto and getero aggression had 12% of children (male and female parity). Hereby, the child sexual abuse is referred to the very hard psychological traumas with negative consequences from light transit psycho-emotional changes to posttraumatic stress disorders with auto aggressive trends. Children and adolescent age psychogenic disorders are characterized with neurotic level of depressive stations and obliterate psychopatholo-
gical manifestation.

ADHD CONTRIBUTES TO THE DYSFUNCTIONAL CONTEXTUAL UNDERSTANDING OF THE EMOTIONAL FACIAL EXPRESSION

INSTITUTIONS
1. Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Department of Psychiatry, Seoul, Republic of Korea
2. Kangbuk Samsung Hospital, Department of Psychiatry, Seoul, Republic of Korea
3. Kyonggi University, Psychology, Suwon, Republic of Korea

AUTHORS
1. Dong-won Shin¹, Dr, M.D., Ph.D., ntour@unitel.co.kr
2. SeungMin Bae², Dr, M.D, manitch@paran.com
3. Soo Jung Lee³, Ms, Ph.D

Objectives
Children with ADHD are at a greater risk for social dysfunction and interpersonal impairment than children without the disorder. The children with ADHD show deficits in recognizing the facial expressions, which cause misinterpretation of social cue. The purpose of this study was to examine whether the diagnosis of ADHD contributes to the dysfunctional contextual understanding of the emotional facial expression.

Methods
We assessed seventy nine children with ADHD and forty eight controls in this study. Kiddie Schedule for Affective Disorders and Schizophrenia-Present and Lifetime Version-Korean version (K-SADS-PL-K) were used to diagnose ADHD. They also performed the Emotional Recognition Test - Revised (ERT). ERT consists of 54 computer-administered items that form a total score and subscales. Stepwise linear regression analysis was performed to test whether the diagnosis of ADHD contributes to the dysfunctional contextual understanding of the emotional facial expression. Age, gender, verbal IQ, performance IQ and total IQ were put as independent variables, and the results of emotion recognition test was put as dependent variable. The analysis was performed using SPSS version 13.0. The level of statistical significance was set at P<0.05.

Results
After controlling for the effects of age, gender distribution and IQ, the diagnosis of ADHD significantly contributes to the score of the emotional recognition test (effect size=12.7%, p<0.01).

Conclusion
Patients with ADHD were less accurate in contextual understanding of the emotional facial expression than control subjects.

MULTISYSTEMIC TREATMENT FOR DISRUPTIVE DISORDERS IN CHILDREN AND ADOLESCENTS

INSTITUTIONS
1. University of Pisa, Child and Developmental Psychiatry, Calambrone - PISA, Italy

AUTHORS
1. Irene Baldi¹, Mrs., MD, irene.baldi@inpe.unipi.it
2. Annarita Milone¹, Mrs, MD
3. Pietro Muratori¹, Mr, MD
4. Azzurra Manfredi¹, Mrs, MD
5. Antonella Paziente¹, Mrs, MD
6. Lisa Polidori¹, Mrs, MD
7. Laura Rugliioni¹, Mrs, MD
8. Filippo Muratori¹, Mr, MD

Aims/Objectives: To analyse the efficacy and the response predictors of a Multisystemic Treatment for Disruptive Behavior Disorders in childhood and adolescence. Methods: 41 subjects 24 DOP and 17 DC were subjected to Multisystemic Treatment (cognitive-behavioural psychotherapy, academic activities, parent-training and social intervention) for 6 months. CBCL, MOAS, CGI-S and CGI-I were administrated before treatment (T0), and after 6 months (T1). A subject was considered Responder (R) to treatment if CGI-I score was 1 or 2, plus MOAS total score decreased of 40%. If a subject not satisfied all criteria, the treatment was repeated for 6 months too (T2). Different t-test and X² analysis were used. Results: 3 subjects were drop-out. After 6 months, 11 subjects were R: CBCL score showed significant decreased in Total Externalizing, Attention Problems, Aggressive Behaviors, and a significant improvement in Social Competence. After 12 months, 21 subjects were R: MOAS significantly decreased in all subscale. To analyzed the response predictors, we examined the subscale scores retrospectively: the CBCL Total, Total Internalizing and Thought Problems at the T0 were significantly lower in subjects R after 6 months than in nR; the MOAS Clastic and Eterodirected Aggressivity subscale remained higher, after 6 months, in subject that were not R after 12 months. DOP was significantly correlated with a later response (12 months). Conclusion: Multisystemic Treatment results effective in reducing aggressive behaviours, conduct problems and psychological impairment in our sample. The treatment act in different way in DC or in DOP, and also DC present two patterns of response.

5. Azzurra Manfredi\(^1\), Dr, MD
6. Filippo Muratori\(^1\), Prof, MD

Aims/Object: To describe the clinical characteristics of a sample of child and/or adolescent inpatients urgently hospitalised.

Metods: 281 consecutive patients, matched in 3 groups by the clinical presentation of the acute symptoms: Externalizing Problems (auto and e erotirected aggressivity, clastics behaviours), Interna-lizing Problems (withdrall, catatonia), and Psicotc syntoms. For each group, epidemiological and clinical features are examined: age, sex, socioeconomic status, Axis I and II diagnosis. Diagnosis is due by clinical observation and by the semi structured interview K-SADS-PL. Each patients is also valutated by CBCL, C-GAS, use of pharmacological therapy.

Results: 45.3\% of sample shows internalizing problems. 16.3\% of patients has not a psychiatric diagnosis before the hospitalization, so the acute symptomatology represent the clinical presentation of psychiatric pathology. 89.3\% of sample don't need a second hospitalization in the 12 months later. Conclusion: This study give us many important information about clinical characteristics and management of a particular kind of psychiatric patient.

In the Center for the social work in Podgorica, in September of the 2005, was formed multica-stigatory operational team for protection the children from the violence and neglect.

The team is composed of the professionals from the Center for the social work-a social operative, a pedagogue, a prosecutor, a judge for the minors, an inspector of the Police Department also for minors, and as circumstances require representatives of the other services. The members of the team operate according their professional power of attorney.

Multica-stigatory operational team for the protection of the children from violence and neglect within the Center for the social work-Podgorica IN 2007 continued the work with 62 children from 25 families, in which had been evidenced the suspicion of the neglect and maltreatment of the children. During the year 2007 is denounced the suspicion of the serious form of maltreatment and neglect 25 children from 17 families.

In the thesis mentioned the authors discuss about attitude from the part of the parent considerate to child who was brow-beat out of the family, and they also mention the reasons for delay of announce-ment, and dilemmas of the testimony in court.

EFFECTIVENESS AND TOLERABILITY OF ATOMOXETINE IN A REAL-WORLD ADHD POPULATION

INSTITUTIONS
1. FSWP, United States
2. University of Pittsburgh, United States

AUTHORS
1. Leo J Bastiaens, Dr., MD, Bastiaensl@aol.com

Objective: To evaluate the effectiveness of atomoxetine in a real-world Attention Deficit Hyperactivity Disorder (ADHD) population. Recently, the issue has been raised that atomoxetine may not be as effective as stimulants for ADHD.

Methods: A retrospective chart review of two nonrandomized groups in one clinic: Patients treated with atomoxetine (n=85) and patients treated with stimulants (n=81). Consecutively evaluated outpatients, between the ages of 5 and 18, diagnosed with ADHD, with or without other conditions, were included. Diagnoses were made with the Mini International Neuropsychiatric Interview and the Child/Adolescent Symptom Inventory. A Global Assessment of Functioning scale (GAF) was performed at all visits, which occurred every two to three months. After maximum one year of treatment, a Clinical Global Impression - Improvement scale (CGI) was subtracted from clinic notes.

Results: There were no significant differences in age, gender, comorbidity, GAF at baseline, GAF at endpoint, or in CGI at endpoint, between the two groups. All patients showed mild improvement, as measured by the CGI, while staying on the same medication for approximately 6 months. Even though more patients on atomoxetine showed side effects, there was a trend for patients to stay on it longer. Average doses and side effect profiles were similar to previous research reports.

Conclusion: Taking into account the limitations of a retrospective chart review in nonrandomized samples, it appears that patients with ADHD benefit as well from atomoxetine as from stimulants.

QUALITY OF LIFE IN PATIENTS TREATED FOR ADHD WITH ATOMOXETINE OR STIMULANTS

INSTITUTIONS
1. FSWP, Pittsburgh, United States
2. University of Pittsburgh, Pittsburgh, United States

AUTHORS
1. Leo J Bastiaens1,2, Dr, Md, Bastiaensl@aol.com

Objective: To evaluate improvement in quality of life in a real-world ADHD population treated with atomoxetine or stimulants. No direct comparisons between atomoxetine and stimulants to improve quality of life in ADHD are available.

Methods: A prospective, nonrandomized comparison between ADHD patients treated with atomoxetine or stimulants in one clinic. Patients were diagnosed with the Mini International Neuropsychiatric Interview and the Child/Adolescent Symptom Inventory. Quality of life was measured with the Health And Life Functioning Scale (HALFS), a 10 item parent rating scale, measuring functioning in health-, academic-, leisure-, family-, and social-related areas. The Global Assessment of Functioning scale (GAF) was used as well. The Sheehan Disability Scale was used to measure parents’ level of functioning.

Results: A total of 84 patients (atomoxetine n=39 / stimulants n=45), with an average age of 11.1±3.3, were followed for approximately 8 months. Co-morbidity was common. There were no significant differences in improvements of quality of life, measured by the GAF or the HALFS, between the two groups. Age, participation in psychotherapy, and parental level of functioning were not correlated with quality of life improvements. Patients with lower baseline scores on the HALFS/GAF improved most.

Conclusions: Both atomoxetine and stimulants led to a modest increase in quality of life in this real-world co-morbid ADHD population. Patients with lower quality of life at baseline improved the most.

DELAY OF MENTAL DEVELOPMENT AT PRESCHOOL AGE: NEUROPSYCHOLOGICAL ANALYSIS

INSTITUTIONS
1. Ural State Medical Academy of Additional Education, Child Psychiatry, Chelyabinsk, Russian Federation
2. State University, Psychology, Chelyabinsk, Russian Federation

AUTHORS
1. Larisa Al. Benko1, PhD, g1966@mail.ru
2. Gennady G. Butorin2, Mr, MD, g1966@mail.ru

Objectives. The purpose of research was to carry out analysis of neuropsychological functions activity at children of preschool age with intellectual insufficiency of a boundary level.

Methods. By means of clinical-psychopathological and neuropsychological methods 62 children of 3-6 years with boundary residual-organic intellectual insufficiency (41 boys and 21 girls) had been surveyed.

Results. The research has shown significant prevalence of motor and nominative speech functions disorders (53.2% and 80.6% accordingly) as dyslalia, dysarthria, infringements of syllabic structure of words, increase the latent period before the answer, reduced nominative function of the speech, reduced active lexicon. Dysfunction of attention has been revealed at 25.8% of children. The rate of mental reactions has been broken in 30.6 % of cases, and in 38.7% the divergence between impellent reactions and intellectual activity was established. The visual-spatial perception appeared broken at 29.0%, constructive skills - at 20.9 %. Imperfection of generalization and allocation of the main attribute was determined at 32.2% of cases. In the drawings (56.3%) perseveration of lines, strong pressing, expressed structural infringements has been revealed. Emotional disorders were observed at 27.4% of children.

Conclusion. Thus, the most vulnerable neuropsychological functions appeared motor and nominative functions of speech (dysfunction of premotor areas of frontal shares and the top departments of temporal shares accordingly), programming and control of mental activity (convexital surfaces of frontal shares), integrative visual-spatial function (dysfunction of TPO zone).

BEHAVIOUR DISORDERS AT DYSPHORIC AND DISTURBING DEPRESSIONS AT CHILDREN

INSTITUTIONS
1. Ural State Medical Academy of Additional Education, Russian Federation

AUTHORS
1. Natalia Betskova
2. Natalia Butorina, MD

Objectives. The purpose of research was to reveal clinical-psycho-pathological features of depressive disorder of behaviour at children at various clinical variants of depression.

Methods. It was permanently surveyed 82 boys of 10-14 years with various forms of broken behaviour combined with emotional disorder of a depressive spectrum. Clinical-psychopathological, clinical-dynamic, psychological of inspection and clinical-anamnestical methods were used.

Results. The research has shown, that at 73.2 % surveyed depression proceeded on dysphoric type. Behaviour disorders at family were shown by runaways from home - 76.7 %, fits of anger - 46.7 %, broken interrelations - 26.7 %, cruelty at family - 15 %. In children's establishment were observed infringement of a mode at 50%, roughness and cruelty at 48.3 %. Among the peers they disposed vagrancy, begging or larceny, cruelty to other people or animals. At 26.8 % surveyed depression was characterized by disturbing. Behaviour in family displayed by falsity and disobedience, larceny and falls of interrelations. In children's establishment were observed infringement of a mode in 50 % cases, roughness and cruelty in 36.4 % cases. Outdoor and at schools they showed vagrancy and larceny at peers.

Conclusions. Thus, at various clinical variants of depression at boys of 10-14 years different forms of disordered behaviour prevailed. At dysphoric variant of depression behaviour carried a delinquency character and covered all spheres of a life. At disturbing depression behaviour were shown more often by disturbing of family relations and school maladjustment.

AUTHORS
1. Subhash Bhargava, Dr., MD, scbhargava146@yahoo.com

The study was conducted to see the burden on the family of having a child with ADHD and the coping strategies employed by them. The parents of 50 children with ADHD were interviewed on the Interview Schedule (Family burden) developed by Pai and Kapoor and Family Coping questionnaire. For comparison parents of 30 children interviewed on the same tools were selected. The burden scores were significantly higher in all the domains in the parents of children with ADHD. The families of the children with ADHD employed positive communication and information as the frequently used coping strategies. The findings are discussed in context of overall management.

IMPACT ON PARENTS OF HAVING A CHILD WITH ADHD

INSTITUTIONS
1. Pt. BD Sharma PGIMS Rohtak, Department of Psychiatry, Rohtak, India

AUTHORS
1. Subhash Chandra Bhargava¹, Dr, MD, sbhargava146@yahoo.com
2. Rajiv Trehan¹, Dr, MD

The study was aimed at evaluating the impact of having a child with ADHD. The parents of fifty school going children with ADHD were studied and compared with the parents of thirty Non ADHD children. The diagnosis of ADHD was made as per DSM-IV criteria. The comparisons were done on common symptoms and stress experienced by them. The tools used were Brief Symptom questionnaire and Disruptive Behaviour Stress Inventory. The parents of the children with ADHD experienced significantly more stress in terms of stress experience and stress degree as compared to the parents of children without ADHD. The parents in the families with ADHD children find routine care giving and child rearing responsibilities as irritating, frustrating and annoying. Most of the stressors relate to the school home work and academic difficulties and problem with teachers. Further the parents of the children with ADHD reported significantly higher levels of anxiety, depression, physical symptoms, occupational difficulties and social concern as compared to the parents of Non ADHD children. The findings are discussed in relation to the sociodemographic variables and management perspectives.

4. Piotr Wierzbinski¹, Mr., Dr.
5. Antoni Florkowski¹, Mr., Dr., MD

Background: Nowadays, mental retardation is no longer considered as a separate diagnosis. Among mentally impaired persons the same psychiatric disorders may be recognized as in general population.

Aim: The aim of the study is to analyse mental disorders determining psychiatric hospitalizations among mentally impaired patients.

Material and methods: Medical documentation of 100 patients hospitalized in Babinski's Hospital in Lodz in years 2006-2007 with diagnosis of mental retardation (F70-F79 according to ICD-10).

Results: Most of hospitalized patients were young men, mentally impaired in the light degree. The most frequent direct reason of hospitalization was aggression towards environment, behavioral changes and psychosis. The most common psychopathological symptom according hospital admission was psychomotor agitation, lower mood, anxiety. The most frequent indirect reason of hospitalization was adverse environment factors or deterioration of unknown reasons of previous psychiatric disorders. The most frequent psychiatric disorders were behaviour disorders, impulse control disorders and psychosis. In more than a half of cases no other diagnosis apart from mental impairment was stated.

Conclusions: Among mentally impaired patients stronger inclination to external expression of emotions is observed. It mainly appears in behavioral disorders and external aggression. Most of hospitalizations are determined by adverse environment factors. Unfortunately, symptoms of psychiatric disorders are still treated as the consequences of mental impairment, not as the manifestations of psychiatric disorders itself.
PREVALENCE OF AUTISM IN R. MACEDONIA (DURING A FIVE YEARS PERIOD)

INSTITUTIONS
1. Institute for Mental Health of Children and Adolescents, Daily Hospital for Children, Skopje, The former Yugoslav Republic of Macedonia
2. Clinic of Psychiatry, Department for Child and Adolescent Psychiatry, Skopje, The former Yugoslav Republic of Macedonia

AUTHORS
1. Meri Boskovska¹, Dr., MD, boskovskam@yahoo.com
2. Marija Raleva², Dr., MD, PhD, mraleva@yahoo.com

Aims: To define the prevalence of autistic spectrum disorder in the R. of Macedonia and to establish early diagnostic procedures.

Methods: Since autistic spectrum disorder is often difficult to be marked off out of the variety of developmental disorders that start in early childhood such as delay in speech and psychomotor development, behavioural problems, it is necessary to establish early working diagnosis. We use the ICD10 and DSM IV diagnostic criteria for autistic spectrum/pervasive disorders, observation and certain diagnostic instruments (Munchen's Functional Developmental Diagnostic Scale; Bayley's Scale for Child Development; Childhood Autism Rating Scale)(1). The diagnosis is established by a multidisciplinary team consisting of child psychiatrist, psychologist, speech therapist and special educator.

Results: During this five years period there are 68 children being diagnosed and followed up. The age range is from 2, 5 to 7 years. The ratio between boys and girls is 5, 8:1. Out of 68 children there was 1 child diagnosed as Asperger's syndrome, 1 as Rett's syndrome, 3 disintegrative psychosis, and 2 with developmental dysphasia. All children were included in the early rehabilitation program, designed individually.

Conclusions: The incidence of the autistic spectrum disorder in children is increasing during the analysed period (2) due to better understanding, diagnosing and treatment of the autistic children, which is very complex and improving during time.

ARIANNA’ JOURNEY A 14 MONTH JOURNEY OF A MULTIMODAL AND MULTI-PROFESSIONAL TREATMENT OF A SEVERELY AUTISTIC YOUNG PERSON

INSTITUTIONS
1. St Stephen's Centre, Learning Disabilities, Birmingham, United Kingdom
2. Care First, Mental Illness and Learning Disabilities, Birmingham, United Kingdom

AUTHORS
1. Ruth L. Brand Flu¹, Dr, MD, amazonicalpha@aol.com
2. Chris Winter², Mr., Chrisw@carefirst.co.uk

Background:
Arianna (pseudonym) also has mild learning disabilities. She has also been extremely tactile defensive. She is chair bound and spends her time screaming. Her family is isolated and are chained by A's rituals. She has been rejected by many services, due to non-attendances

Aim:
To create a therapeutic environment
To decrease anxiety levels
To promote eye contact and other pro-social behaviour
To get her out of the house

Method:
Continuing support worker's input, who demonstrates playful activities
Home visits and meetings at outpatient clinic
Extensively reassessing her condition to create a working formulation of problems and strengths

Working through mother and tentatively directly with the young person
Getting dad involved
Exploring parental issues of guilt and resentment
Addressing counter transference and avoidant/obsessive parallel processes
At a later stage referral to a therapeutic orientated day centre, which provided in reach input by tailor made interventions such as interactive 'shouting' and boundary setting, including to parents who did not assent for psychotropic medication

Results:
The shouting which increased at the first session, was gradually replaced by insulting remarks and eye contact. Exploring of guilt resulted in a catharsis of Mum reliving a very traumatic birth, which was followed by the emergence of creative talents and increased co-therapy input. Two hours interactive shouting resulted in tactile behaviour of the young person. Six weeks into the in-reach input, A. had a successful journey to the day centre

“HOT” AND “COOL” EXECUTIVE DYSFUNCTION IN CHILDREN WITH ADHD

INSTITUTIONS
1. Cuban Neuroscience Center, Havana, Cuba

AUTHORS
1. Tania M Bravo, Dr., MD, MsC, tmbravo2003anizer172@gmail.com
2. Migdyraí Martín, Dr., MD, MsC, PhD
3. María Antonieta Bobes, Dr., PhD
4. Lidice Galan, Dr., PhD

ADHD is regarded as an umbrella construct that subsumes multiple potentially dissociable but overlapping cognitive profiles. The objective of the current study was to reconsider the impairment on executive function (EF) in ADHD on the light of distinction between affective/motivational (“hot”) and more purely cognitive aspects (“cool”) of EF, examining the performance on a neuropsychological battery (5 tasks).

Twenty-five children with ADHD and 25 healthy controls were administered measures of estimated intellectual ability, sustained attention, set shifting, inhibitory control, delay aversion, and decision-making. Behavioural ratings were obtained. The controls were matched in gender, age and IQ with the ADHD group.

ADHD children performed worse than controls in all tasks. A discriminant analysis was conducted, the combination of the entire measures discriminated correctly the 88% of both groups. There was an overlapping distribution of impairment based on percentage of individuals in each group “impaired” (>1.5 SD). Twenty percent of children with ADHD showed dysfunction only in “hot” EF, 8% in “cool” EF, and 60% had dysfunction in both. The probability of impairment in “hot” and “cool” EF was independent.

The presence of impairments in incentive, motivational and reward-related processing suggests that both ‘hot’ and ‘cool’ EF deficits are present in children with ADHD. The separability of motivational and EF processes support current dual pathway models of ADHD. A reconceptualization provides a means to transcend the limits of current models of executive dysfunction in ADHD and suggests a plan for future research on cognition.

HUMORAL-PHYSIOLOGICAL FEATURES OF SEMIOLOGY AT THE MIXED DISTURBING-DEPRESSIVE DISORDERS AT TEENAGERS

INSTITUTIONS
1. Ural State Medical Academy of Additional Education, Child Psychiatry, Chelyabinsk, Russian Federation

AUTHORS
1. Natalia Yer. Butorina, Mrs, MD, g_butorin@mail.ru
2. Fedor F Belikov, Mr, g_butorin@mail.ru

OBJECTIVES. The aim of study was to determine influence of the simulated psycho-emotional stress on teenagers with depressive disorders and various levels of uneasiness with changing the level of cortisol.

METHODS. 73 teenagers in the age of 12-17 years with semiology of depressive disorders have been surveyed. All surveyed have been divided into two groups: with the raised level of uneasiness (F41.2, n=41) and with a normal level of uneasiness (F 32.0, F32.01, n=32). With the purpose of the greater validity the cortisol level in saliva was defined three times with the help immuno-fermentive analysis. In a role of psycho-emotional stress the combination of psychological techniques has been chosen. Estimation of somato-vegetative displays was carried out the same way.

RESULTS. At the first group the cortisol level in the two first tests appeared authentically above parameters of the second group. There was no decrease in cortisol parameters from the first to the second test at representatives of the first group. Somato-vegetative infringements within the stressful test have been more expressed at the first group. Changes poststressful cortisol have shown, that at the increased uneasiness more expressed answer to stress is observed.

CONCLUSION. Parameters of cortisol level and somato-vegetative reactions are in direct correlation dependence on a level of uneasiness.

THE IMMUNE STATUS AT CHILDREN WITH RESIDUAL-ORGANIC PSYCHOSYNDROME

INSTITUTIONS
1. Ural State Medical Academy of Additional Education, Russian Federation

AUTHORS
1. Natalia Butorina¹, MD
2. Natalia Blaginina¹

Objectives. The purpose of research was to define a role of the immune status in pathogenesis of residual-organic psychosyndrome at children.

Methods. Investigated clinical-immunological features of 124 children in the age of 8-10 years with non-psychotic forms of residual-organic psychosyndrome (ROPS) were verified by clinical, psychopathological, neurological, neuropsychological and neurophysiological methods.

Results. The following clinical-psychopathological variants of ROPS were allocated: somatopathic (which basis were somatovegetative disorders); psychomotor (with early defect of a level and quality of motor maturity); cognitive (with primary deficiency of cognitive functions activity); affective and conative (with emotional-willed and/or behavioural disorders). Each variant was characterized by a continuum of disorders that allowed to determine easy, moderate and heavy degrees. It was established, that immunobiological disorders are mostly expressed at moderate and heavy degree, mainly, at somatopathic, cognitive and affective variants, and are leveled in a number of moderate and easy disorders. Character of interrelations of researched systems correspond to development of nonspecific adaptable reactions of organism and depend on clinical-dynamic structure of residual-organic psychosyndrome.

Conclusions. Complex ROPS therapy with the account of clinical-immunological parameters can be added with immunotropic means, both for correction of parameters of the immune status, and for more successful reparation of the basic clinical displays of residual-organic psychosyndrome.

EMOTIONAL AND BEHAVIORAL PROBLEMS AND THEIR RELATIONSHIP WITH ATTRIBUTIONAL STYLE AND SOCIAL FUNCTIONING AMONG ADOLESCENTS BROUGHT UP INSTITUTIONALLY AND IN NATURAL FAMILIES

INSTITUTIONS
1. Collegium Medicum N. Copernicus University, Dept. of Psychiatry, Child & Adolescent Psychiatry Ward, Torun, Poland
2. Faculty of Pedagogy, N. Copernicus University, Department of Special Pedagogy, Torun, Poland

AUTHORS
1. Miroslaw R Dabkowski¹, MD, PhD, domirka@uni.torun.pl
2. Monika I Dabkowska², PhD, mbacker@poczta.onet.pl

The internalized and externalized symptoms, likewise the subjective attribution of events is connected with pathology of attachment, deprivation of emotionally attractive patterns with exposition to destructive ones and with the feeling of helplessness and of lack of the influence on the surroundings. The influence of the a/m relations on social functioning is also indicated.

The research included adolescents aged 13, brought up in Children’s Home (CH) from one region of the country (42 persons) and in natural families (NF) (84 persons were matched). The profiles were assessed according to Achenbach ASEBA System; also the CASQ by Seligman and formal results of education were taken into account.

Results: there was a higher frequency of internalized and externalized disorders in CBCL and YSR within the CH adolescent group than in NF group; high differences in the school test results; and almost threefold better results in competence scales. The connection of social functioning and internalized and externalized disorders was demonstrated only among the CH group. There were no differences revealed in the style of attribution between the CH and NF group; although only in the case of CH children there was a connection of the pessimistic style of event explanation with attention disorder and conduct (aggressive) disorders.

Conclusions: keeping in mind the genetic and cultural pre-selection of children brought up in CH, it is needed to consider their higher intensity of disorders and problem behaviour, and worse social functioning than their peers, as well as smaller chances of improvement - resulting from consolidated pessimistic attribution.

** COURSE OF BIPOLAR DISORDER IN PRESCHOOL AGE CHILDREN

**INSTITUTIONS**
1. University of Cincinnati, Psychiatry, Cincinnati, OH, United States
2. AstraZeneca Pharmaceuticals LP, Wilmington, DE, United States
3. Cincinnati Children’s Hospital Medical Center, Psychiatry, Cincinnati, OH, United States

**AUTHORS**
1. Arman Danielyan¹, MD, adanielyan@yahoo.com
2. Sanjeev Pathak², MD, frontal cortex@gmail.com
3. Robert A. Kowatch³, MD, PhD, robert.kowatch@cchmc.org

**Objectives:** Bipolar disorder (BD) is a chronic and recurrent condition. However, its clinical course in pediatric population has not been well studied.

**Methods:** The data was gathered through a comprehensive retrospective review of the psychiatric records of 26 preschool age (3 to 7 year old) children, treated as outpatients at Cincinnati Children’s Hospital Medical Center from 2000 - 2004. CGI-S and CGI-I scores were assigned retrospectively to each subject. All treating physicians were board-certified/eligible child and adolescent psychiatrists.

**Results:** The median time to respond to pharmacotherapy in the clinic was 4 weeks (mean 12.88±26). Time to response (CGI=1 or 2) to pharmacotherapy was 4 weeks for 15 subjects (57.7%); 5 to 8 weeks for 3 subjects (11.5%); and more than 12 weeks for 8 subjects (30.8%). Sixteen (61.5%) out of 26 subjects relapsed during the course of treatment. Ten (38.5%) subjects had at least one relapse, 4 subjects (15.4%) relapsed twice, and 2 subjects (7.7%) had 3 relapses during the course of their treatment. For those patients who relapsed (n=16), the duration of being a responder before a relapse, was 19.69 weeks (SD= 18.402). Only 5 out of 16 patients (31.25%) remained symptom-free for 4-8 weeks; and only in 2 patients (12.5%) a remission lasted for more than a year.

**Conclusions:** BD with onset in preschool years is associated with high recovery and relapse rates. It is often underdiagnosed. The questions of development of age-appropriate diagnostic criteria, long-term prognosis and treatment strategies used in this population require further intensive investigation.

P-01-282

**CDT PREDICTS HEAVY DRINKING DAYS IN ADOLESCENT ALCOHOLICS: PRELIMINARY DATA**

**INSTITUTIONS**
1. Medical University of South Carolina, Psychiatry, Charleston, SC, United States

**AUTHORS**
1. Deborah Deas¹, Dr., MD, deasd@musc.edu

**Objectives:** Carbohydrate deficient transferring (CDT) is a biological marker that has been shown to be sensitive and specific in detecting heavy alcohol consumption in adults. To date, there is no published evidence of its utility in adolescent alcoholic populations. The purpose of this study was to explore the usefulness of CDT as a biological marker for drinking among adolescents.

**Methods:** Blood from 25 treatment seeking adolescent alcohol dependent subjects and 8 adolescent controls was collected and assayed for % baseline CDT levels.

**Results:** Alcohol dependent adolescents did not differ from controls on mean % baseline CDT levels (2.33 vs. 2.32), although alcohol dependent subjects endorsed significantly more drinks per drinking day, percent heavy drinking days, and peak number of drinks than controls. The relationship between drinking variables and % baseline CDT was highly correlated with percent heavy drinking days (r=.54; p<02).

**Conclusions:** Although data suggests CDT levels at baseline don’t differentiate alcohol dependent adolescents from controls, CDT level is highly correlated with percent heavy drinking days among alcohol dependent adolescents. It is possible that adolescents have not begun drinking heavy amounts for enough years to affect the liver metabolic pathway that will elevate CDT above normal levels but enough to begin to show changes related to drinking. CDT levels may be useful in clinical practice and research for detecting change in heavy alcohol consumption over time. Further exploration of CDT with a larger sample size in this population is warranted.

Many adolescents with autism and severe mental retardation show hypersexuality: public masturbation, genital exposure in public places and libidinous approach to family members and other children. Such inappropriate behavior are reiated to prejudice and serious family troubles. Cimetidine, a histamine H2 antagonist, has improved hypersexuality and inappropriate sexual behavior in elderly dementes patients. In this paper we present two cases of mental retarded adolescents (13 and 14 years old) who showed clear dysfunction hypersexuality. These patients received cimetidine (100-400 mg/day) for the last one year showing a considerable improvement in hypersexuality and no side effects for the use of the drug.

CHILD ASTHMA AND ADHD - STRATEGY FOR MULTIDISCIPLINARY COUNSELING

INSTITUTIONS
1. Medical University, Neurology, Sofia, Bulgaria
2. Medical University, Pediatrics, Sofia, Bulgaria

AUTHORS
1. Victor E. Donev, MD, dr.donev@gmail.com
2. Silvia A. Shopova, Assoc. Prof., PhD, sylviashopova@yahoo.co.uk

Objective
Some of the children suffering from chronic conditions like bronchiasthmatic children with behavioral deviation. These children were referred to clinical psychologist in periods without bronchial obstruction. Half of them (12 patients) met the DSM-IV criteria for ADHD. Each co-morbid child was neurophysiologically evaluated with a routine EEG. In 2/3 (8 patients) findings were abnormal. Child psychiatrist excluded other psychiatric disorder or syndrome, for which some of the symptoms of ADHD are typical. Genetic counselor excluded developmental delay of these children and genetic disorders with mental retardation. Parents were also counseled and family predisposition for ADHD was found for 5 probands.

Discussion
The proposed strategy is the first native attempt to find common etiologic aspects for both conditions in the sense of psychosomatic dependency, taking into consideration the family predisposition to ADHD.

5. Marketa Zackova, Dr., mzackova@fnbrno.cz
6. Ivana Drtilkova, Prof., CSc., idrtilkova@fnbrno.cz

Objectives: In an association study design polymorphisms of selected genes were analyzed in 119 boys diagnosed with ADHD, aged 7 - 13, as well as in a control group. Within a follow-up study clinical and biological markers were studied in 30 adolescents (aged 14 - 18) with persistent form of ADHD.

Method: Clinical pedopsychiatric examination, criteria of chronic ADHD (DSM-IV), Conners Rating Scale focused on ADHD diagnostics up to 18 years and a semi-structured interview were used. Psychological characteristics concerning ADHD „core” symptoms were assessed by clinical tests (d2, MFPT-Czech-version) and computer administrated neuropsychological tests. Isolated DNA served as a template for polymerase chain reaction and the candidate genes polymorphisms were detected (DRD2, COMT, ACE, IL-6, CCR5, TNF-alpha AGT, MAO-B, IL-2, Mu opioid receptor, BDNF, DRD4 and DAT1). Statistical analysis used the CSS Statistical system (StatSoft, Tulsa, USA).

Results: A significant difference was found between the ADHD and control groups in TAI A polymorphism of the DRD2 gene - in the ADHD group the frequency of A1 allele (p<0.003) and the genotype A1A1 (p<0.008) were higher, in DAT1 findings of atypical genotypes were more frequent in the ADHD group (p<0.007). Significant correlations between the results of some neuropsychological tests and genes for neuro-/immunomodulators (IL-6 and TNF-alpha) and the gene for BDNF were found. After 5 years of follow-up the persistent form of ADHD was found in the majority of ADHD subjects. Potential predictors of the course of the disorder are discussed.

Supported by the IGA MZ CR project nr. 9298-3.

At the end of 90's of previous century, certain studies among the etiological researches of neuropsychiatric disorders revealed a distinct relationship between Sydenham's chorea, motor disorder appearing in childhood caused by rheumatic fever, and obsessive-compulsive disorder. Accordingly, there has been an increasing debate on possible autoimmune mechanisms that triggers it and the role of Group A ß-hemolytic Streptococci in etiopathogenesis of OCD. In 1998 Swedo et al. documented poststreptococcal cases of OCD and/or tics in children and adolescents, without the symptoms of Sydenham’s chorea, and they named it PANDAS, as an acronym for Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal Infections. Neuroimaging findings revealed increased striatum in these patients. In following research, PANDAS is associated with, besides symptoms of OCD, with emotional liability, separation anxiety, oppositional behaviors, cognitive deficits, motor hyperactivity, and eating disorders.

Our paper shows development of polymorphic psychiatric disorders in twelve years old girl, where restrictive type of anorexic phenomenology and compulsive symptoms prevail in actual clinical manifestation.

Key words: PANDAS, OCD, anorexia
P-01-287
ADOLESCENT’S HOSPITALIZATION IN PSYCHIATRIC WARD:
THE COMPLEXITY OF CLINICAL EXPERIENCE

INSTITUTIONS
1. Psychiatric Care Unit ‘Ospedale Galliera’, Department of Mental Health, Genova, Italy

AUTHORS
1. Luigi Ferrannini¹, Dr., luigi.ferrannini@galliera.it
2. Cristina Venturino¹, Dr., cristina.venturino@galliera.it
3. Irma Franceschi¹, Dr.
4. Paola Brolis¹, Dr.
5. Sergio Calabro¹, Dr., sergio.calabro@galliera.it

Objective:
To highlight benefits and drawbacks of the admission into a psychiatric ward of adolescents with acute psychic problems.

Methods:
Case histories of under 18s, admitted from 2002 to present, were analysed.

Results:
The admitted adolescents are 35 (8 females and 27 males). 5 have had multiple admissions and the total is 51. 29% is discharged within the first day, 53% within three days.

Origins:
51% are from Central and South America and North Africa. 54% are alcohol and drug-using. Reasons of admission: psychomotor agitation / behavioural disorder 50% - acute confusional state 18% - drug and alcohol abuse 12% - prescription drugs abuse 8% - self-harming behaviour 8% - psychosis 2%. Diagnosis at discharged: personality disorder 26% - emotional and behavioural disorder 17% - behavioural disorder 9% - drug intoxication 11% - alcohol intoxication 11% - drug and alcohol intoxication 6% - adjustment disorder 8% - depression 6% - psychosis 3% - anorexia nervosa 3%.

Conclusions:
Admitting an under 18s means taking care quickly of the entire household and the patient’s social network. The admission is also the opportunity to plan an individual therapeutic project and to tackle psychological and relational problems. In this setting it is possible to allow the expression and the elaboration of new growing stimulus and regressive feelings.

Asperger syndrome (AS) is a disorder of early childhood characterised by social deficit, subtle communication impairment and excessive idiosyncratic interests.
Children with AS also showed characteristic cognitive problems of visual-motor integration, visual-spatial perception and visual memory that many researchers attribute to right hemisphere dysfunction.
In this study a collection of drawings painted by children with Asperger Syndrome are presented in an attempt to investigate the nature of the visual-spatial deviations in these children.

1. Estefania Gago¹, Dr., MD
2. Lara B Vilela², Dr., MD, larabvilela@gmail.com
3. Luis Ferreira¹, Dr, MD

Autism is a life-long neurodevelopmental disorder characterized by impairment in three areas: social interaction, communication and repetitive patterns of behavior, restricted interests and activities. As they grow older most individuals will continue to need significant family and community support. In these patients, particularly the ones with high-functioning autism, comorbid disorders like ADHD, impulse-control disorders and OCD are common, and increase the potential for misdiagnosis. So, identifying these disorders in adult life is frequently difficult and depends heavily on development history.

Our aim is to study the evolution of children and adolescents with diagnosis of autism spectrum disorder through adulthood. English-language publications from de MEDSCAPE database (2005-2007) including clinical series were reviewed. A sample of twenty adult patients that had been diagnosed as suffering from autism at the Child and Adolescent Psychiatry Unit of Centro Hospitalar do Porto was retrospectively studied through clinical records reviews. After looking for their actual location, interviews were conducted and present record files were consulted to find out diagnosis, treatment approaches and social setting integration.

CONCLUSION: the importance of using life course perspective when considering questions of change and development among people with an autism spectrum disorder point to the need of better liaison between child and adult psychiatry which are too apart in Portugal.

STABILITY/CHANGE OF DSM DIAGNOSES IN CHILDREN AND ADOLESCENTS: A COHORT STUDY

INSTITUTIONS
1. Queen’s University, Hotel Dieu Hospital, Psychiatry, Kingston, Ontario, Canada

AUTHORS
1. Sassan Ghazanshahi¹, Dr., MD, s_ghazanshahi@yahoo.ca
2. Nasreen Roberts¹, Dr., MD, robertsn@hdh.kari.net

Objectives:
1. Examine changes or stability of DSM diagnosis in children and adolescents from childhood to young adulthood
2. Examine, which, if any, diagnoses are stable over time
3. Discuss the instability in DSM diagnoses in this population from a developmental perspective

Methods:
This study used a “Cross-Sectional Cohort” design to assess the stability of diagnosis over time. The sample was drawn from a source population cross-sectionally and then outcomes assessed retrospectively over a specified time period. A computerized database was used to examine the stability or change of diagnosis amongst those seen at least twice as inpatient or outpatient at an academic Child and Adolescent Psychiatry division between 1994 and 2007. The sample consisted of children and adolescents born in 1983, 1984 and 1985. Data will be analyzed using the SPSS software. Stability of diagnoses will be estimated through calculation of positive and negative concordance rates and kappa coefficients.

Results:
Data analysis is in progress at the time of this abstract submission and will be presented when it is completed over next 6 weeks. However preliminary examination of data reveals a total of 427 patients in our database; of which 261 patients were seen more than once. Of these, 52% were born in 1985, 28% in 1984 and 20% in 1983. In terms of gender distribution, we have 139(53%) female and 122(47%) male patients.

Conclusion:
The nature of this study did not allow a choice over the sample size; However, this is not inconsistent with previous studies. Once results are analysed, detailed conclusion will be added.

Attention-deficit/hyperactivity disorder (ADHD) is a common disorder characterized by inattention, hyperactivity and impulsivity with a tendency to long term course. ADHD affects 5-10% of children and, by itself or combined with comorbidities, brings serious functional deficits to an affected person.

The neurobiology of ADHD is not completely understood although recent imaging studies implicate the role of the cerebellum (1). The cerebellum contributes significantly to cognitive functioning presumably through cerebellar-cortical pathways involving the pons and thalamus (2).

That is why we have conducted a study using International Cooperative Ataxia Rating Scale (ICARS) and an objectification of clinical cerebellar signs by the stabilometry and the posturography as well as psychological tests (WISC III, Conners’ Continuous Performance Test II, Tower of London - Drexel University, Auditory - Verbal Learning Test, Test of Verbal Fluency, Rey – Osterreith Complex Figure Test). The goal of the trial was to examine a possible relationship between cerebellar neurological signs, specific cognitive deficits and ADHD symptomatology severity.

We present our first results in a sample of 15 patients aged 7-11 years with ADHD confirmed diagnosis. Exclusion criteria consisted of mental retardation, pervasive development disorder and organic brain damage. However, results are limited by the small sample size.

INCIDENTS OF PSYCHIATRIC DISORDER AMONG ADULTS WITH ADHD

INSTITUTIONS
1. Private Practice, Psychiatry, Allentown/Pennsylvania, United States

AUTHORS
1. Houshang G Hamadani, Dr., MD, DLFAPA, hghamadani@msn.com

Objectives: In recent years the number of patients diagnosed with Adult ADHD has increased. The objective of this study is to determine the incidents of other psychiatric disorders among these patients.

Method: The records of all patients seen in my private office during a 6 month period were reviewed. Those with diagnosis of ADHD were identified, and incidents of other psychiatric disorders were recorded. We also investigated the effects of treatment with other medications in addition to stimulant medication in this group.

Results: Data analysis revealed that about 10% of patients with general psychiatric problems also have ADHD.

Conclusion: We found that adult patients with ADHD can present themselves to the psychiatrist with a variety of complaints. These complaints can be based on the symptoms of different psychiatric disorders. The outcome of our study also showed that successful treatment of other psychiatric disorders enhances the effect of stimulant medications which are used to treat ADHD.

RELATIONSHIP BETWEEN LIFESTYLE FACTORS AND DEPRESSION IN JAPANESE THIRD-YEAR STUDENTS OF JUNIOR HIGH SCHOOL

INSTITUTIONS
1. Nagasaki University Graduate, School of Biomedical Science, Nagasaki, Japan
2. Institute of tropical medicine, Nagasaki University, Nagasaki, Japan

AUTHORS
1. Masaharu Nagae, Mr, m-nagae@nagasaki-u.ac.jp
2. Hiroki Ozawa, Dr, MD, ozawa@nagasaki-u.ac.jp
3. Hiroko Hanada, Dr, PhD, hhanada@nagasaki-u.ac.jp
4. Sumihisa Honda, Dr, PhD, honda@nagasaki-u.ac.jp

OBJECTIVES:
The purpose of the study was to investigate mental health condition in third-year students of junior high school who were preparing for entrance examination of high school.

METHODS:
A survey of self-administered questionnaire was conducted to investigate their lifestyle factors at home and school, from October to December, 2005. A total of 783 students (355 boys and 428 girls) who were in the third grade of junior high school responded to the survey. Their depressive symptoms were assessed by the Depression Self-Rating Scale for Children (DSRSC). A high-DSRSC-score was defined when the score exceeded the threshold value of 15. The effects of factors on the frequency of subjects in the high-DSRSC-score group were analyzed using a linear logistic model. The odds ratio (OR) and its 95% confidence interval (CI) were calculated for each factors in the model.

RESULTS
A high-DSRSC-score was observed in 248 students (32%). The frequency of high-DSRSC-score was significantly higher in those who slept more than 8 hours (OR: 1.65; 95%CI: 1.12, 2.43), those who preferred fish dish (OR: 2.03; 95%CI: 1.39, 2.96), those who did not enjoy life at school (OR: 5.99; 95%CI: 3.79, 9.47), those who disliked studying (OR: 1.66; 95%CI: 1.15, 2.38), and those who rated their health as bad (OR: 3.43; 96%CI: 2.28, 5.15). However, the proportion of high-DSRSC-score was not different between sexes (boys 30% and girls 33%).

CONCLUSION
It was indicated that the lifestyle factors at home and school affected mental health of third-year students of junior high school.

TREATMENT OF TOURRETÉ’S SYNDROME IN CHILDREN AND ZIPRASIDON

INSTITUTIONS
1. Faculty Hospital, Department of Child psychiatry and clinical psychology, Children Hospital, Brno, Czech Republic

AUTHORS
1. Viktor Hartoš, MUDr. Mgr., vhartos@fnbrno.cz

Tourette’s syndrome (TS) is a relatively common childhood-onset disorder defined by persistent motor and vocal tics and frequently associated with obsessions, compulsions, and attentional difficulties. No specific cure yet exists, but symptoms are often treatable with various medications, behavioural therapy and alternative treatments. The decision about whether to treat will depend on the degree to which the tics are interfering with the child's normal development. The goals of treating TS should not be just to completely eliminate all the tics and other symptoms that a patient has, but to relieve tic-related discomfort and to achieve a control of TS symptoms that allows the patient to function as normally as possible. The contribution describes experiences with ziprasidon used in the treatment of more than 15 children (age 7-18) with moderate and severe symptoms of TS. Treatment with ziprasidon was initiated at 5 mg/day. Dosage was gradually increased, on clinical indications, to a maximum of 0.5 mg/kg/day (one or two doses), when the effect was sufficient. Minimum side effects was observed.

Objective: The purpose of this study was to investigate whether differences in performance between ADHD and normal control in Chinese-speaking society and the effects of stimulant medications on attention and impulsivity as measured by continuous performance tests (CPTs).

Methods: 25 6-12 years old un-medicated ADHD with normal intelligence and hearing completed a randomized, double-blind, placebo-controlled, within-subject crossover trial with MPH (0.3mg/kg). A visual sustain attention CPT before and 1.5 hrs after were applied. Total error (TE), omission error (OE), commission error (CE), hit rate (HR) and reaction time (RT) were recorded from ADHD and age matched normal children.

Results: Compare to normal control, prolonged reaction time (p = 0.049) was observed in un-medicated ADHD. Compare performance difference before and after MPH (MPH) and performance difference before and after placebo (I placebo) in ADHD. Total error (t = 3.261, p = 0.003) and omission error were decreased (t = 3.584, p = 0.001), hit rate was increased (t = -3.726, p = 0.001) after single dose of MPH treatment. Compare to normal control, reaction time was shortened and normalized after MPH treatment.

Conclusions: Our research supports single dose MPH increase CPT performance in childhood ADHD. Mainly increase attention, accuracy and speed reaction times. This result also supports the utility of CPTs in evaluating the effects of medication on attention in childhood ADHD.

FACTORS ASSOCIATED WITH REPEATED ADMISSION TO CHILD AND ADOLESCENT INPATIENT UNIT AT A PUBLIC MENTAL HOSPITAL

INSTITUTIONS
1. Kai-Suan Psychiatric Hospital, Department of child and adolescent Psychiatry, Kaoshiung, Taiwan Republic of China

AUTHORS
1. Rong-Rong Huang, Dr., MD, et112878@yahoo.com.tw
2. Kuan-Hsu Chen, Dr., MD

Objective: The purpose of this study was to identify clinical and demographic variables that correlated with repeated admission to a child and adolescent inpatient unit located in southern Taiwan.

Methods: Data from 119 consecutive admissions over a 24-month period were abstracted from medical records for retrospective analysis. Repeated users of admission were defined as those individuals receiving three or more admissions during the study period. Statistical comparisons were made between repeated and non-repeated users groups. Logistic regression analysis was used to predict the repeated users.

Results: Of 113 consecutive admissions, 45 (39.8 %) were identified as repeated users, 68 (60.2 %) were non-repeated users. There were no significant difference between gender, age and IQ testing between these two group. Compare to non-repeated users, repeated users were significantly more likely to be earlier onset, had previous hospitalization, remained in the hospital longer, had multiple diagnosis, special educational placement, previous history of suicide ideation or attempt, aggression behavior within six months before admission, more physical abuse history and lived in a non-conformity family. Logistic regression analysis showed that significant predictors for repeated users were: age (OR=1.517), age of onset (OR=0.603), diagnosis classification was behavior disorders (OR=0.026), aggression behavior within six months before admission (OR=7.986), and non-conformity family background (OR=6.341).

Conclusions: Our finding indicate that factors associated with repeated admission were aggression behavior before admission, non-conformity family background, younger age of onset and diagnosis classification other than behavior disorders.

FACTORS RELATED TO USE OF RESTRAINT ON YOUTH INPATIENTS AT A PUBLIC MENTAL HOSPITAL

INSTITUTIONS
1. Kai-Suan psychiatric hospital, Dept of child and adolescent psychiatry, Kaohsiung, Taiwan Republic of China

AUTHORS
1. Rong-Rong Huang¹, Dr, MD, et112878@yahoo.com.tw
2. Kuan-Hsu Chen¹, Dr, MD

Objective: The study examined the characteristic factors associated with repeated restraint during inpatient psychiatric treatment in southern Taiwan.

Methods: A retrospective chart review of child and adolescents who were admitted to inpatient units located in southern Taiwan between January 2005 and December 2006. Repeated users were defined as those individuals receiving two or more restraints during the same admission. Demographic and clinical characteristics of two groups of youths were compared. Logistic regression analysis was used to predict the repeated users.

Results: The sample of 113 youths was predominately male, mean age was 15.61 ± 2.49 ages, totally 238 restraint incidents occurred during study period. More than half restraint incidents occurred in the afternoon and the evening. The major incidents of restraint were due to assault behaviors. The most incidents took place at the common area. 41(36.3 %) were identified as repeated users and 72(63.7 %) were non-repeated users. There were no significant difference between gender, age and IQ testing between these two groups. Repeated users were significantly more earlier onset, remained in the hospital longer, multiple diagnosis, had history of suicide and sexual abuse, had aggressive behavior before admission. Logistic regression analysis revealed remained in the hospital longer (OR= 1.03), multiple diagnosis (OR= 2.97), behavior disorder (OR= 4.42) were associated with repeated users of restraint.

Conclusions: Our finding indicate that factors related to use of restraint on youth inpatients were remained in the hospital longer, multiple diagnosis and diagnosed as behavior disorders.

STUDY OF STRUCTURE & SYMPTOMS OF ANXIETY DISORDERS IN IRANIAN PRESCHOOLERS

INSTITUTIONS
1. islamic azad university of arsenjan unit, psychology, Iran (Islamic Republic of)

AUTHORS
1. Gholamreza Chalabianloo¹, Dr, phd, chalabianloo_f@yahoo.com
2. Fatemeh Jahani¹, Dr

Abstract Body:

Objectives: Anxiety is one of the responses of organism to stressful conditions of life. Anxiety disorders are one of the most prevalent disorders that have some subtypes. Anxiety disorders spread from childhood to adulthood. As mentioned by DSM-IV-TR, the only anxiety disorder during childhood is separation anxiety disorder (Kaplan & Kaplan, 2007). But some researchers indicated other anxiety disorders during childhood. Spence and et al (2001) indicated the different structure of preschooler's anxiety that consisted of 5 different factors during childhood similar to disorders diagnosed in adulthood disorders.

Methods: In order to study of structure of anxiety disorders in Iranian preschoolers, parents of 400 students of Shiraz preschools were selected by random sampling procedure. They completed the questionnaire that designed to evaluate different types of anxiety symptoms. The questionnaire has acceptable psychometric structure such as high reliability and validity.

Results: The factor analysis of data with varimax rotation indicated 4 different factors among symptoms. The results showed that Iranian preschoolers, opposite to what proposed in DSM-IV-TR, indicated 4 types of anxiety disorders. These factors are related to what is diagnosed in DSM as social phobia, specific phobia, obsessive - compulsive disorder and generalized anxiety disorder. Results indicated that there is only a significant difference between sex groups in specific phobia in which boys had more phobia than girls (t= 2.82, p< 0.05).

Conclusion: Our results proposed the importance of revision in the classification of anxiety disorders during childhood in DSM-IV-TR.

PERFORMANCE ON CONTINUOUS PERFORMANCE TEST AND RITALIN DOSAGE IN ADHD

INSTITUTIONS
1. Chang Gang Memorial Hospital, Department of Child Psychiatry, Tao Yuan 333, Taiwan Republic of China

AUTHORS
1. Hsueh-Ling Chang, Dr, MD, chang0687@adm.cgmh.org.tw
2. Hsin Yi Liang, Dr, MD, sophia0730@yahoo.com.tw
3. Ming Hwa Lee, Ms, MS, chang0687@adm.cgmh.org.tw

Aim: The purpose of this study is to determine whether a relationship existed between measures on Continuous Performance Test (CPT) and Ritalin dosage.

Method: 300 consecutive ADHD children who underwent CPT were recruited. Their demographic data, results of CPT, and dosage of Ritalin 3 months after initiation of Ritalin treatment were recorded.

Results: Among the 300 ADHD children, 58.3% (N=175) received Ritalin treatment, 41.6% (N=125) children were either lost for follow up, received other pharmacotherapy and/or behavior therapy. Of the 175 children who received Ritalin treatment, 85.7% was male (N=150) and 14.3% was female (N=25), their age range between 5 to 14 years (8.28±2.2). Average Ritalin dosage is 18.14±8.7 mg (5-45 mg). In this study, age was found to be positively correlated with Ritalin dosage (Pearson correlation 0.163, p=0.032); Hit RT ISI Change and Hit SE ISI Change on CPT were negatively correlated with Ritalin dosage (Pearson correlation -0.152, p=0.044, Pearson correlation -0.162, p=0.031).

Conclusion: CPT is applied widely in clinical setting for the assessment of inattention and impulsivity. Previous studies had assessed the correlation of CPT with ADHD symptoms. In this study, we tried to understand if CPT measures could predict treatment dosage, and found two measures in CPT that were negatively correlated with Ritalin dosage.

DEPRESSION IN CAREGIVERS OF AUTISTIC CHILDREN; CROSSSECTIONAL DESCRIPTIVE

INSTITUTIONS
1. Faculty of Medicine, Chiangmai University, Psychiatry, Chiangmai, Thailand

AUTHORS
1. Chawanun Charnsil, Dr., MD, ccharnsi@mail.med.cmu.ac.th
2. Nirumol Bhatia, Dr., MD

Having autistic children is a stressful event for a family. This can cause caregivers to have depressive disorders. On the other hand, depression of a caregiver can affect the development of autistic child.

Objectives: The purpose of this study was to examine depression in caregivers of autistic children. Two main objectives were: (1) to find the prevalence of depression in caregivers of autistic children; and (2) to find factors that correlate with this depression.

Method: 27 caregivers of autistic children were interviewed by general practice physician using mini international psychiatric interview to examine whether they have depressive disorder according to DSM IV or not. They were asked to complete a relevant questionnaire to determine factors influencing their depression. The autistic children were assessed severity with childhood autistic rating scale.

Result: 7 in 27(25.9%) having depressive disorders. 4 in 27(14.8%) meet criteria of major depressive disorders. 3 in 27(11.1%) meet criteria of dysthymic disorders. Caregivers who have depression have low education compared with the normal group. Age, number of children, period of caregiving and severity of autistic children are not different in these two groups.

Conclusion: Depressive disorder is common for caregivers of autistic children. This finding suggests that we should screening depressive disorders in caregivers of autistic children especially in low education group so that we can give early intervention and can promote development of autistic child.

PATTERNS OF MENTAL DISORDER IN CHILDREN & ADOLESCENTS IN 2006-07 IN AN INDIAN RURAL CLINIC

INSTITUTIONS
1. Calcutta Pavlov Hospital, Psychiatry Dept., Kolkata (Calcutta), India

AUTHORS
1. Asis Krishna Charya¹, r., D.P.M., D.I.H, dr_asisacharya@yahoo.com

OBJECTIVES: Reports on “Caring for Children and Adolescents with mental disorders” highlights
1) 20% of children & adolescent suffer from disabling mental disorders (WHO2000).
2) Suicide is the 3rd leading cause of death in adolescents worldwide (WHO2001). MDD often begins in adolescents, is associated with substantial psychosocial impairment and risk of suicide.
3) Conduct disorders tends to persists in adolescent & adult life, is associated with juvenile delinquency, adult crime, dissociative behavior, marital problems, unemployment and poor physical health.

Prevalence of child mental disorders were studied in a rural clinic 124 km away from the capital city in 2006-07 keeping all these in view.

METHODS: Study was conducted in "Mono-susrusha" in Midnapore town 124 km from Calcutta. All patients those attended the clinic of both sexes in the age gr. of 6-16 yrs. were recorded for study. Only 84 boys girls who attended the clinic for >6 visits were retained for evaluation. Their diagnostic formulation were based on ICD-10 criteria. Their mean age was 10.2 years & median age was 11 years.

RESULTS: Mental Retardation with behavior disorders (14-10%), Specific disorders of speech and language, developmental disorders, scholastic skill specially that of arithmetic skills, pervasive development disorders-childhood autism, disorders like hyperkinetic conduct disorders (ADHD) are very few. Conduct Disorders, socialized & unsocialized, mixed disorders of conduct and emotion, nonorganic enuresis, Stuttering, tic disorder in 1 boy, and early onset adult-type disorders like phobic-anxiety disorders, panic disorders in adolescent, somatoform disorder, and schizophrenia in adolescent, and also Bipolar disorder in adls. are there. O.C.D, anorexia nervosa were detected in girls. Alcohol abuse and substance abuse was not found.

CONCLUSIONS: This prevalence study in clinic have some similarity with prevalence study of mental disorders in children and adolescents based population in Europe United states (Libson et al 2001; Verhulst 2004).

AUTHORS
1. Roberto E Chaskel¹, Dr., MD, chaskel@cable.net.co

24 boys improved on all behavioural items when on continuous treatment with Risperidone in low dosage. Evaluations by Occupational Therapists, Language Therapists, Neuropediatricians and parents will be shown. The improvement in mild to moderate autism with or without epilepsy with the use of medication, outdid the prognosis given by parents and health workers when the medications was not allowed for children in the late 90’s.

2. Tzu Yu Chen², Mrs., Master

Although the integrated or dynamic model benefits of conceptualized depression during adolescence has been documented, little is known about what familial and individual characteristics are associated with higher levels of participation.

Using structural equation modeling, this Asia of Taiwan study examined the extent to which family factors (i.e., family cohesion, maternal function), adverse life events, early codependency, and adolescents’ cognitions (i.e., automatic thought and interpersonal resolving style) predicted depression during junior high school among adolescent subjects had 250 boys and 246 girls. Five instruments were conducted in this study.

Results showed that the tendency of codependency could enhance the degree of negative automatic thoughts and passive interpersonal problem-solving attitude to lead an increased rate of depression in adolescent, and codependency could through negative automatic thoughts raise the effect of adverse life events exacerbated depression of adolescent.

The multi-determined pathway among of adolescent depression was discussed in the study. Researchers would be wise to consider on multiple way to prevent and decrease adolescent depression.

PROMOTING JOINT ATTENTION IN TWO LOW-FUNCTIONING CHILDREN WITH AUTISM

INSTITUTIONS
1. National Chung Cheng University, Department of Psychology, Chia-Yi, Taiwan Republic of China

AUTHORS
1. Chung-Hsin Chiang¹, Dr., psychc@ccu.edu.tw
2. Ya-Ling Pang¹, Ms., roxannetw@yahoo.com.tw
3. Shu-Jung Chiang¹, Ms, alulu18@gmail.com

Objective: Deficits in joint attention (JA) have been well studies in autism and also the focus of treatment effort in the western countries. The purpose of current study was to examine the efficacy of JA intervention for children with autism in Taiwan.

Methods: Two 5 year-old children (Child A and B) were diagnosed with low-functioning autism and referred by teacher of special preschool in southern Taiwan. The strategies of JA intervention originally developed from Kasari, et al. (2006) which integrated ABA model and milieu teaching conducted 30 minutes for 24 sessions in 3 months. Both structured assessment of JA and adult-child interactions were collected pre and post intervention by independent assessors.

Results: Results indicate that two children improved on certain behaviors. (1) During the sessions, Child A, a boy with single word only could develop responding of JA (proximal pointing) to initiating JA (showing); Child B, a girl with no verbal ability could increase her responding of JA (reaching) to initiating JA (distal pointing). (2) After the intervention, both children initiated more distal pointing and responsiveness to JA on the structured JA assessment and more child-initiated JA in adult-child interaction.

Conclusions: JA intervention provides preliminary promising data on the specificity and generalizability of JA development for two low-functioning children with autism. Future studies need to examine long-term effects and recruited more participants for replication.

ATTENTION-DEFICIT/HYPERACTIVITY DISORDER (ADHD) SUBTYPES ON ADHERENCE AND EFFICACY OF OROS METHYLPHENIDATE AMONG POOR ADHERENTS TO IMMEDIATE RELEASE METHYLPHENIDATE IN TAIWAN

INSTITUTIONS
1. Chang Gung Memorial Hospital- Kaohsiung Branch, Department of Psychiatry, Kaohsiung County, Taiwan Republic of China
2. National Taiwan University Hospital & College of Medicine, Department of Psychiatry, Taipei, Taiwan Republic of China

AUTHORS
1. Wen-Jiun Chou1, Dr., wjchou@adm.cgmh.org.tw
2. Susan Shur-Fen Gau2, Dr, Md and PhD, gaushufe@ntu.edu.tw

Objective: To find the determinants in switching medication to OROS methylphenidate (MPH) among poor adherents to immediate release (IR) MPH and the determinants for adherence to OROS MPH; and to compare the core symptoms of Attention-Deficit/ Hyperactivity Disorder and treatment response in subtypes.

Method: 240 children, aged 6-16 years, were identified as poor adherents to IR MPH and were included in the study. 137 were switched to OROS MPH. The rest remained on IR MPH. The measures included Clinical Global Impression, the SNAP version IV scale, and questions regarding parent-child interaction, classroom behaviors, academic performance and side effects.

Results: The determinants for switching medication to OROS MPH among poor adherents are children who had received higher dose of IR MPH, had multi-dose drug administration, and had more severe inattention symptom. Poor adherents had longer duration of IR MPH treatment. No predictive factor was found for the adherence to OROS MPH. The ADHD combined and hyperactive-impulsive types have more inattention, hyperactivity, and oppositional-defiant symptoms compared to the inattentive type. The treatment response was more evident in the ADHD combined type.

Conclusions: For children with ADHD who have poor adherence to IR MPH, switching medication to OROS MPH may improve their treatment adherence and obtain better efficacy. For those who are not switched to OROS MPH, it is important to resolve their problems of poor adherence in order to achieve optimal treatment outcome.

6. Asma Bouden1, Dr
7. Mohamed Béchir Halayem1, Dr, PhD

Background: Since the advent of the modern criteriology, the symptoms of the youthful depressive core are the same ones as those of the adult. The aim of our work is to analyse the effects of age and gender on depressive symptoms.

Methods: Patients included in this study are the new consultants aged from 6 to 15 years (N=34), presenting a first major depressive episode. The evaluation consisted of a clinical examination supplemented by a semi structured diagnostic interview (K-SADS-PL). The severity of depression was assessed by means of the Child Depression Rating Scale-Revised (CDRS-R). DSM IV’s symptoms and CDRS-R’s Items were compared across age and gender.

Results: Significant age-differences were found for depressive mood and feeling of guilt, which were more frequent in the group of children and for suicidal acts which were found exclusively in the group of adolescents. Cognitive and psychomotor disorders were more frequent in the group of children, while irritability, anhedonia, feelings of worthlessness and hopelessness, recurrent thoughts of death, insomnia and loss of appetite were more frequent in the older age group. Feeling of guilt was significantly related to the group of boys, as recurrent thoughts of death, cognitive and psychomotor disorders. Social withdrawal, feelings of worthlessness, of hopelessness, affective disorders, loss of appetite, insomnia and suicidal acts were consistently more frequent in girls.

Conclusion: Results suggest that depressive symptoms in youths may vary across age groups. Sex and age-related patterns of depressive symptoms must direct treatment approaches that are more developmentally sensitive.

ASSAULT BY A MAN WITH ASPERGER SYNDROME - ASPERGER SYNDROME INFLUENCES THE FORM OF CRIME

INSTITUTIONS
1. Shakujii Cocolo-no Clinic, Tokyo, Japan

AUTHORS
1. Kazumasa Kimura¹, Dr, kaz20k@hotmail.com

Introduction
A 35-year-old man with Asperger syndrome stabbed a 25-year-old woman several times, including in her neck, using a 13-cm knife. I discuss Asperger syndrome and the form of crime.

Case
The subject met the victim at a sex industry. He knew she saw him as a customer and thought that he was matter-of-fact about this. According to him, she asked to borrow some game software from him. However, according to her, he left the software without her request. She lost the software and he asked her to return it. This process annoyed her, but he did not realize that. She contacted his superior at his company and requested his dismissal due to his stalking behaviors. He was upset because she told lies.

Subsequently he discovered from a magazine that she would be visiting a certain location. He thought that he should give her a painful experience and took the knife. He traveled around the city with another woman with the knife in his bag. The next day he decided to ambush the victim. He first went window-shopping, spent time in a café and dozed off. Finding her, he ran towards her and stabbed her.

Influence of Asperger syndrome
The attention of the subject became focused on giving the victim a painful experience and he was unable to recognize that she might die if he stabbed her neck. He behaved as usual, as if he had not been thinking about stabbing her. This form of crime is associated with Asperger syndrome.

4. Courtney Merritt¹, Ms., BS, merritc@musc.edu
5. Natalie Johnson¹, Mrs., MA, johnsong@musc.edu

Objective: The period of adolescence is marked by exploration, further separation from parental authority and attempts to individuate. Our objective in this study was to explore the prevalence of risky behaviors (violence, substance abuse, and sexual related behaviors) among adolescents in an inpatient psychiatric sample.

Methods: Subjects were 105 inpatient adolescents (60 males and 45 females) age 12-17 admitted to the Institute of Psychiatry at the Medical University of South Carolina. Subjects completed a modified version of the Youth Risk Behavior Survey (Center for Disease Control). Statistical Analyses were conducted exploring prevalence of risky behaviors and gender differences.

Results: About one-fourth of the sample endorsed ever carrying a gun and 22% reported carrying a weapon in the past 30 days. Males were significantly more likely to carry a gun and engage in physical fights in the past year. Thirty-four percent (34%) of the sample reported marijuana use in the past 30 days and 23% engaged in binge drinking. Ten percent (10%) of the sample admitted to engaging in sexual intercourse prior to the age of eleven. Females were significantly more likely to endorse suicidal ideations and attempt suicide in the past year.

Conclusions: Risky behaviors are highly prevalent among psychiatric inpatient adolescents. There are few gender differences in the areas of violence, substance use and risky sexual behaviors. Adolescent research and clinical interventions should have a targeted component which addresses risky behaviors.

REHABILITATION OF CHILDREN WITH MENTAL RETARDATION, HAVING HEREDITARY DISEASES

INSTITUTIONS
1. Ural State Medical Academy of Additional Education, Russian Federation

AUTHORS
1. Irina Lebedeva
2. Natalia Butorina

Objectives. The aim of the study was to estimate efficiency of medical-psychological and psychosocial rehabilitation of children with mental retardation with the rare forms of hereditary diseases.

Methods. Under supervision there were children with mental retardation, having a hereditary pathology: Ehlers-Danlos syndrome (n=2), Marfan illness (n=5), Recklinghausen neurofibramatose (n=8), Sturge-Weber angiomatose (n=2), Hippel-Lindau angiomatose (n=4). Age structure of children was from 2 till 18 years. At research have been used clinical, laboratory - biochemical, citogenetic methods.

Results. Psychosocial rehabilitation included obligatory visiting child establishments of a compensating kind where polyprofessional inspection of children with allocation of conducting disorder and restrictions of ability to live was carried out, medical-correctional and improving-preventive work with obligatory (2 times in one year) an estimation of results. The primary goal of training and education was children's adaptation to a practical life. The special attention was given to physiological measures and sports occupations. The overall performance with children has been closely connected to features of child-parental relations. Constant psychotherapeutic work with parents were carried out, the belief in an opportunity of improvement of a state of health was supported. Within one year sanatorium treatment was carried out also.

Conclusion. Spent actions allowed to improve quality of a life and promoted socialization children.

CASE REPORT: CREATIVE BODY MOVEMENT THERAPY FOR AN ADULT WITH AUTISM

INSTITUTIONS
1. Fu Zen Catholic University, Department of Psychology, Taipei county, Taiwan Republic of China

AUTHORS
1. Tsung-Chin Lee, Dr., superchiang@mail2000.com.tw

Objective: The purpose of this study was to use the strategy of creative body movement therapy (CBMT, Evan, 1980) to help an adult with autism for the reconstruction of the body-sense of self, furthermore, to improve his initiation of emotional expressions so as to facilitate the interpersonal relationship.

Methods: A 21 year-old adult diagnosed with middle-functioning autism was referred to this author by the agent of institutional center in northern Taiwan. CBMT was conducted 60 minutes per week for 10 months consecutively. The structure movement profile scale and unstructured parent-subject interaction were collected pre- and post- intervention by independent assessors.

Results: (1) Using the CBMT improved the patient's repetitive/ stereotyped behaviors and interests. After the intervention, the patient's fixed movement patterns and verbal commands were modified to freely acting by his body space and connection. (2) Via the strategies of CBMT, the patient's condition was improved on overall body sensation, body-self connection, and self-other relationship. (3) Patient's mother reported that during CBMT, patient's interpersonal communication improved steadily. The patient was able to express more about his emotional state and eventually initiated more social interactions with friends.

Conclusions: The CBMT enhances the possibility and flexibility of body-self association for an adult with autism. Furthermore, it improves the individual's social emotional initiation and his interpersonal relationship. Further studies need to examine long-term effects of this intensive intervention and recruited more participants for shorter sessions.

OBJECTIVE: Self-reported indicators of health status provide interesting information about the psychological component of health and the experience of social roles. The aim of the present study is to investigate the relationship between socioeconomic status and self-reported psychological level of health among Greek adolescents.

METHOD: Cross-sectional survey of 2363 adolescents aged 15-18 years old attending 10 secondary schools in northwestern Greece. Self-reported psychological health and self-reported level of general health were assessed in two separate five-item scales. Socio-economic variables included parent's education and employment status, subjective adolescent's school performance and subjective assessment of the family's financial difficulties by the adolescent.

RESULTS: 30.8% of the adolescents (girls: 40.1%, boys: 19.9%) evaluated their recent psychological health as fair or poor. No statistically significant association was found between poor health and parental occupation or father's education. Adolescents with lower personal social position, as measured by their school grades, reported poorer psychological health. Financial difficulties in the family were also associated with poor psychological health. In girls only, mother's lower educational qualifications were associated with poorer psychological health.

CONCLUSION: Despite certain level of equalisation, significant socio-economic inequalities can be observed among Greek adolescents, especially when subjective measures of psychological health and socio-economic status are used.

OBJECTIVE: Attention-deficit/hyperactivity disorder (ADHD) encompasses a broad constellation of behavioral and learning problems. These patients are also characterized by low blood long-chain polyunsaturated fatty acid concentrations; however their supplementation effect on ADHD symptoms is not clear. It was recently (1) shown in children with inattention that consumption of n-3 phosphatidylserine (PS) for 3-mo favorably affected their visual sustained attention performance. We aimed to evaluate in children with ADHD the effect of n-3 PS on ADHD symptoms and wellbeing.

METHODS: In this 15-week, randomized, double-blind, placebo-controlled, parallel study the impact and tolerability of 150 mg b.i.d. n-3 PS were investigated in 200 children (6-13-y) with ADHD. Efficacy was assessed by teachers' Conners Rating Scale (CRS) and strength and difficulties questionnaires (SDQ) - school version and clinicians who filled Clinical Global Impression of Improvement. Additional measures included parental rating of behavior (CRS and SDQ - home version) and wellbeing (Child Health questionnaire - Parental Form 50), and continuous performance test (Test of Variables of Attention). Safety evaluation included adverse event reports, vital signs, and parents' Barkley' side effects rating scale. RESULTS: The interim results of 40 children that were randomly assigned in a 2:1 ratio to n-3 PS or placebo will be presented.

CONCLUSION: n-3 PS impact on ADHD symptoms at school and home as evaluated by teachers, clinicians, and parents will be discussed.

6. Carlos Finkelsztein1

Objective: To determine the frequency in adolescents between 13 and 21 years old of suicide attempt with their parents psychotropic medication.

Material and Method: This is a quantitative, prospective, observational and transversal study. The variables considered were age, gender, cause of admission, suicide method. When the attempt was done with pills we considered what kind of pills and whom they belong to; we also asked about familiar psychiatric history and familiar history of suicide attempt and suicide.

Results: We analyzed data from 85 patients. 67% (n=57) were female and 33% (n=28) male. Age range was between 13 and 21 years with a mean of 18.05 ± 2 years. The principal cause of admission was suicide attempt (40.5 ± 3.68%) (n=45). The suicide attempt method most frequently used was the ingestion of pills (77.8 ± 9.6%) (n=35).

Discussion: 29 adolescents (82.8 ±16.32%) attempted suicide with their parents pills; within this medication 93% (n=27) were psychotropics. The availability of suicide methods is related directly to suicide. Without this methods near many autoaggressive impuls may be restrained. The importance of the availability of these methods is often underestimated instead of being modified by prevention.

Deficits in the ability to perceive others facial emotions’ is a core feature of Autism-Spectrum disorders (ASD). Previous studies investigating the ability to perceive facial emotions have predominately employed the use of static rather than more ecologically valid dynamic facial emotions. This raises concerns particularly when a clinical sample is investigated as their ability to process facial emotions may be underestimated. Previous research that has assessed dynamic facial emotions, it is suggested that static and dynamic facial emotions are processed within different neural regions. The current study aimed to investigate with the use of steady state probe topography (SSPT) whether static and dynamic emotions were processed within different neural areas. Twenty-six (14 male: M=21.64, SD=3.99; 12 females: M=24.42, SD=4.36) individuals participated in the current study. Conditions included scrambled faces, passive viewing of faces, a gender face task and an emotion face task.

Results indicated that static facial emotions with respect to gender were predominately processed within the frontal region and dynamic facial emotions were predominately processed with in the temporal region. The current study suggests that static facial emotions are non-canonical stimuli and are processed within the mirror-neuron circuit within the frontal cortex and more ecologically valid dynamic facial emotions were processed within the temporal region consistent with the superior temporal sulcus for biological motion. This has important implications for interpreting studies with an sample of individuals with ASD, as previous results that suggest no response to static images may be underestimating their ability to recognize more ecologically valid dynamic stimuli.

STATISTICAL EVALUATION OF 15 YEARS OF PATIENTS SINCE THE OPENING OF A CHILD AND ADOLESCENT PSYCHIATRIC CLINIC

INSTITUTIONS
1. Department of Psychiatry, Asahikawa City Hospital, Asahikawa, Japan

AUTHORS
1. Kensuke Miyazaki, Mr., MD
2. Akira Takei, Mr., MD, a_takei@city.asahikawa.hokkaido.jp
3. Kazuhiko Mera, MR., MD
4. Yuzuru Sato, Mr., MD
5. Yoichi Haraoka, Mr., MD

Aims: To clarify the clinical features of a Japanese child and adolescent psychiatric clinic, we studied the data from outpatients who have visited the child and adolescent clinic that opened in our psychiatric department since January 1991.

Methods: Subjects were 3- to 18-year-old patients who first visited our child and adolescent psychiatric clinic between January 1991 and December 2005. Statistical analysis was performed based on the medical records of these patients.

Results: Subjects comprised 1340 patients (516 boys, 824 girls), accounting for 14.6% of all new outpatients including adults in our department. The number of new patients showed an annual increase. The percentage of patients over 12 years was 85.1%. According to ICD-10 classifications, the percentage of F4 was the highest (49.4%), followed by F9 (13.5%), F2 (11.4%) and F5 (9.8%). In recent years, numbers of F8 and F9 have gradually increased with increases in the numbers of patients with hyperkinetic disorders and pervasive developmental disorders. Of the 1340 patients, 429 (32.0%) showed school refusal, representing the most commonly observed chief complaint in child and adolescent patients.

Conclusion: These results indicate that treatment of adolescents with neurotic disorders (F4) is important for our clinic. Establishment of a substantial psychiatric treatment system is necessary to properly treat adolescent patients.

2. Ewa Gajewska, Dr., PhD, karasinska1@wp.pl
3. Wlodzimierz Samborski, prof., MD, PhD, ewamojs@amp.edu.pl

Manual Ability Classification System (MACS) is a scale for children aged 4 to 18 years, diagnosed as suffering from cerebral palsy. MACS is based on spontaneous manual activities of a child, with special attention paid to the use of objects within its grasp. MACS focuses on the level of the hand function (in five degree scale) of every child and is based on observation how the child copes at home, at school and in social relations. This scale seems a very useful tool, estimating the manual abilities with no regard on the general level of motor development; it describes function what is extremely important for therapists to properly design further therapeutic programs and their improvement to achieve best results of rehabilitation.

The aim of the study was to measure the manual function in children suffering from cerebral palsy, in relation to their mental impairment, speech abilities and incidence of epilepsy.

Material and methods:
Material consists of 90 children, who were diagnosed as suffering from cerebral palsy. The level of intelligence and clinical data were collected by analysis of data from history of disease.

Results show that children with epilepsy showed worse manual function than children non suffering from epilepsy. Children with deep mental impairment showed the worst manual function. Children in whom development of the speech was better showed also better manual function.

RELIGIOUS MORAL VALUES AS PREVENTION FACTOR OF BEHAVIORAL DISORDERS DURING ADOLESCENCE

INSTITUTIONS
1. University Clinical Centre Tuzla, Departments of Psychiatry, Tuzla, Bosnia and Herzegovina
2. University of Tuzla, School of Medicine, Tuzla, Bosnia and Herzegovina

AUTHORS
1. Izet Pajevic
2. Mevludin Hasanovic
3. Amra Delic

Aim: The aim of this study is to determine the influence of an attitude related to religious moral values on mental stability and on prevention of behavioral disorders during adolescence.

Methods: The sample consisted of 240 mentally and physically healthy high-school adolescents of both sex, divided into groups equalized by gender, age, school achievement, behavior, family structure and the level of exposure to psycho-social stress. Subjects were assessed with regard to the level of belief in certain basic ethical principles derived from religious moral values. Moral Belief Index of the two groups of subjects were compared. In the sample selection the measuring instruments were used to assess moral, religious and social profile. A standardized test battery (Freiburg's Personality Questionnaire/Das Freiburger Personlichkeitsinventar - FPI, Profile Index of Emotions - PIE, Life Style Questionnaire - OM) is used for the assessment of personality structure including personality profile, emotional profile and coping mechanisms of subject. Statistical processing is done in SPSS 10.01, and statistical methods applied in this study were t-test, Pearson's correlation test (r), Hi-square test.

Results: Neuroticism, depressiveness, spontaneous and reactive aggressiveness, as well as irritability, emotional instability, transfer and defensive orientation is negatively associated with the moral belief index, while intellectualisation and reactive formation positively associated with the moral belief index.

Conclusions: It is undoubtedly shown that the level of respect of religious moral values is positively correlated with mental stability during adolescence, which reduces the risk of behavioral disorders specific to adolescence.

Key words: religious moral values, adolescence, mental stability

6. Darko Dimovski

Aims: To present our experience with olanzapine in treatment of schizophreniform disorders, and to examine its efficacy and safety in this population.

Method: In the study were included 10 patients (6 boys and 4 girls) which were followed-up for 6 months with BPRS and PANSS and laboratory test and BMI at starting of treatment, after three months and six months.

Results: The mean daily dose of olanzapine was 11.8 (range 7.5-15 mg). All children aged 12-17 years showed significant improvement in 6 weeks, with subsequent reduction of psychopathology at each checkpoint. Glucose levels were at normal level and we do not observed statistically significant elevation on BMI.

Conclusion: Olanzapine was safe and effective in treatment of young population.

5. Angelina Filipovska¹

Aim: To examine the efficacy and safety of risperidone in a randomized clinical study of adolescents with aggression and subaverage IQ.

Method: We randomly assigned 20 patients aged 9-17 years who were hospitalized and then followed up for three months. We used clinical scales BPRS, CGI and AIMS.

Results: The mean daily dose was 2.67mg/day (range 0-5-4mg). We observed significant reduction of aggressiveness after two weeks of treatment, and afterwards mild tiredness we reduced the therapy. Extra pyramidal symptoms were absent or very mild. Other unwanted effects included sialorrhea and slight weight gain.

Conclusion: Our results suggested that risperidone is effective for reduction of aggression and disruptive behavior in adolescent with subaverage IQ and is well tolerated as well.

One of kinds of group psychotherapy is socially psychological training which represents training to skills and skills in spheres of dialogue, activity, personal development and correction (in particular aggressive behaviour, depression, phobias, etc.). Aggression is formed mainly during early socialization at children’s and teenage age and in this age is optimum for preventive maintenance and correction. It is offered to consider in more details specificity of concrete training for teenagers with a high level of the aggression, carried out on base Rehabilitation and Diagnostic Center Ministry of the Health of Ukraine.

Objective: Target group: teenagers with the expressed form of aggressive behaviour. of participants - 6-7 person, heterogeneous on gender structure. Number of employment - 10, duration of everyone - 2 hours.

The overall aim of training is concretized in the following problems(tasks): development of ability to empathy; training technics overcoming of aggressive pulses and technics of relaxation.

Methods: As base methods of training were used: group discussion and role game in its various updatings and combinations, and technical equipment and receptions neurolingvistic programming, transactive the analysis, psychoplay.

Results: Group experience facilitates processes of self-disclosing, self-research and self-knowledge that not always can be achieved at individual psychocorrectional and psychotherapeutic work. Thus, the group psychotherapy is a basis active psychocorrectional works, it raises adaptive resources of the person.

The purpose - studying mental and psychosomatic disorders at children and teenagers and development of recommendations on the most effective methods of psychosocial rehabilitation.

**Objective:** complex psychological inspection of 78 children and the teenagers. 42 pers. (53.9 %) have been established diagnosis of vegeto-vascular dystonia.

**Methods:** clinical method, psychodiagnostic method (painters techniques «The Nonsense Animal», «Figure of family», «The House, a tree, the person», the Children's questionnaire of neuroses, a technique of diagnostics personal alarm of pupils, questionnaire EP I, a questionnaire of fears), group psychotherapy.

**Results:** 50 pers. (64.1 %) boundary disorders were observed on a background residual cerebral insufficiency. Neurotic variant 38 pers. (48.7 %) - affective infringements, alarm, emotional intensity, infringement of mental activity, incidental depressive components; characterological variant 28 pers. (35.9 %) - the infringements of behaviour which are not reaching pathocharacterological types of behavioural deviations. High level of uneasiness - at 59 pear. (75.6 %). The complex approach to carrying out of rehabilitation actions of children and teenagers in Rehabilitation and Diagnostic Center includes both medical, and social - psychological components.

**Conclusions:** psychological characteristics of children and teenagers with mental and psychosomatic disorders, specify a high level neurotisation and family desadaptation, low frustrationaly tolerance, uneasiness, depression. These features of their person should be taken into account by development of methods of social - psychological rehabilitation, correction of intrafamily attitudes, including inadequate approaches to education.

**THE AGGRESSIVE FORM OF BEHAVIOUR OF TEENAGERS - AS RESULT OF DESTABILIZATION OF ECONOMY IN THE MODERN STATE**

**INSTITUTIONS**
1. Donetsk National Medical University by M.Gorky, Rehabilitation and Diagnostic Center Ministry of the Health of Ukraine, Donetsk, Ukraine
2. Rehabilitation and Diagnostic Center Ministry of the Health of Ukraine, Department of Medical & Social Psychology, Konstantinovka, Donetsk region, Ukraine

**AUTHORS**
1. Oleg A. Panchenko¹, Dr., Proff., rdckonst@mail.ru
2. Elena B. Simomenko², Mrs., rdckonst@mail.ru

Aggressive behaviour of teenagers as consequence of destabilization of economy in the state, is caused by absence of the settled system of values and stereotypes, decrease in standard of life as at teenage age there is a formation of character and other bases of the person. From here there is necessity for early revealing behavioural problems, characterological features of teenagers and formation optimum psychological correctional work with the purpose of prevention desocialized teenagers.

**Objective:** In total research had been covered 53 persons. The experimental group have made 12 person (23%) which were characterized by presence by aggressive strategy of behaviour and 41 person of teenagers (control group) whom this form of behaviour it was not peculiar (77 %).

**Methods:** Research included use of method of supervision, «primary interview » and a complex psychodiagnostical techniques, such as: a technique of color choice by Lushier, Thomas's technique and multifactorial personal questionnaire MMPI.

**Results:** Technique MMPI, has allowed to define prevalence of a scale “Impulsiveness” at 67 % (35 person from the general group), surveyed, that is spoken about presence hyperthim variant reacting and difficulty in self-checking, with the leading protective mechanism with replacement.

**Conclusions:** In view of the personal features of teenagers revealed by us inclined to aggressive behaviour, we came to the conclusion about necessity of creation integrative psychocorection models of work with such children: primary interview, socially psychological training, individual psychological correction to use of techniques cognitical and analytical psychotherapy.

DEPRESSIVE SYMPTOMS AS MEASURED BY THE CDI IN A POPULATION OF KOREAN CHILDREN

INSTITUTIONS
1. Seoul Metropolitan eunpyoung hospital, psychiatry, Seoul, Republic of Korea
2. Kangwon national university hospital, psychiatry, Chunchon, Republic of Korea

AUTHORS
1. Woon Jin Jeong¹, Dr, MD
2. Jong-Ik Park², Dr, MD, PhD, lugar@kangwon.ac.kr

Background: The Children’s Depression Inventory (CDI) is one of the most widely used self-report instruments to assess childhood depression, and it has been especially valid for epidemiological purposes.

Aims: The aim of our study is to assess self-reported depressive symptoms in a school sample of Korean children by gender, using the Korean version of the CDI. In addition, a factorial analysis was performed on the 27 items of CDI in the subjects in order to identify possible composite dimensions.

Methods: All the participants were 5th-grade 4,370 students in elementary schools (2,165 males, 2,186 females and 19 unknown) in 2005-2006. The initial factors were extracted by means of maximum likelihood factor analysis and then rotated according to promax criteria in order to achieve a simple structure. Only those items with a loading of .30 or greater were included in the identified factors.

Results: The CDI mean score was 13.16 ± 6.88. Eight hundred ninety-five (20.48%) children showed clinically significant scores above 19 points. There was no significant difference of mean scores between boys and girls. Factorial analysis yielded four factors, such as dysphoria, social problems, externalizing/self-deprecation and school problems. The factor which accounted for the highest variability was externalizing/self-deprecation in boys, but dysphoria in girls.

Conclusion: The frequency of participants who scored 19 or above was significantly higher than those of in other westernized countries. Despite of insignificant difference in the CDI score, the gender difference should be considered to assess childhood depression.

CONSUMER SATISFACTION WITH CHILD AND ADOLESCENT MENTAL HEALTH INPATIENT CARE

INSTITUTIONS
1. Institute of Mental Health, Serbia and Montenegro

AUTHORS
1. Ana Radojkovic¹
2. Milica Pejovic Milovancevic¹
3. Smiljka Popovic Deusic¹

Aims
Measuring consumer satisfaction is recent achievement in health care in Serbia linked to the introduction of human rights related international standards. The aim of the study was to explore the differences between children and parents in satisfaction with child and adolescent inpatient mental health service.

Method
Self report Questionnaires (Child and Parent Version) for evaluating the satisfaction with treatment were administered to 40 children, aged 12-18 years, and to their parents at the end of the child’s hospital treatment. The questionnaires are based on the questionnaires developed by H. Remschmidt and colleagues at the Dept. of Child and Adolescent Psychiatry, Philipps-University, Marburg.

Results
High levels of overall satisfaction with received services were reported both by children and parents. Most of children (85%) reported that they were understood and respected by the therapists but quite often (37%) they doubted if their disease is curable. The parents were more optimistic regarding the outcome of child’s difficulties but less satisfied with the effects of the treatment on their family functioning. This was more frequent in multi-problem families or in parents living far away from Belgrade and not able to attend regularly the sessions for the parents.

Conclusion
The measuring of consumer satisfaction is a valuable starting point in the process of improving the treatment procedures and raising the standards of care within the existing services. It can help in better understanding and meeting the needs and expectations of children and their parents.

THE OUTCOME OF ATTACHMENT DISORDERS IN SCHOOL PERIOD AND EARLY ADOLESCENCE IN ADOPTED CHILDREN

INSTITUTIONS
1. Clinic of Psychiatry, Department for Child and Adolescent Psychiatry, Skopje, The former Yugoslav Republic of Macedonia
2. Institute for Mental Health of Children and Adolescents, Daily Hospital for Children, Skopje, The former Yugoslav Republic of Macedonia

AUTHORS
1. Marija Raleva¹ Dr., MD, PhD, mraleva@yahoo.com
2. Meri Boskovska² Dr., MD, boskovskam@yahoo.com
3. Kamka Paketicova¹ Dr., MD
4. Angelina Filipovska¹ Mrs, afilipovska@yahoo.com

Objective: Analysis of the outcome of attachment disorders in adopted children in later behavioral organization in respect to the caregiving style of their parents.

Method: The sample consisted of 21 adopted children age 6-12 years, and their respective adoptive parents. The children's attachment organization was assessed by Child Attachment Interview, and the caregiving parent style was assessed by Adult Attachment Interview (1). Actual behavioral problems of children were assessed by Child Behavior Checklist.

Results: The profiles on the Child Attachment Interview and Adult Attachment Interview were highly complementary (2). 6 children manifested inhibited type of attachment disorder, which highly correlated with internalizing behavioral problems and 15 children manifesting disinhibited type which correlated with externalizing behavioral problems. Behavior disorders were ranked as internalizing (such as: anxiety, phobic, psychosomatic, depressive symptoms) and externalizing (such as hyperactivity, conduct disorders, aggressive and antisocial behavior).

Conclusion: Attachment disorders are severe risk factors in adopted children which contribute to multiple behavior disorders and emotional problems in later latent and early adolescent period.

SUBSTANCE MISUSE IN LEARNING DIFFICULTIES - AN EMERGENT FIELD?

INSTITUTIONS
1. North Bristol community learning difficulties team, Bristol, United Kingdom

AUTHORS
1. Salim J Razak¹, Dr, MUDr, salimrazak@hotmail.com

Aim: The poster aims to present some background information on substance misuse in persons with learning difficulties and present this as an emergent field in psychiatry.

Method: An academic day of talks by professionals working in substance misuse was arranged by the North Bristol Community Learning Difficulties Team for staff working in learning difficulties. The various presentations are described on the poster. Questionnaires were circulated before and after the talks to gauge peoples attitude towards this field, including questions about their previous training and experience. People were also asked about what may be useful for future services.

Results: In total 17 paired questionnaires were completed. All respondents felt that the topics were relevant to a degree. Most people had encountered cases in the last 6 months where they felt that substance misuse was a significant problem. However, over half of respondents had no experience or training in substance misuse. Of suggested future directions many respondents agreed that further training was essential as well as closer collaboration between learning difficulties and substance misuse services.

Conclusions: Persons with learning difficulties have problems accessing mainstream substance misuse services and these patients are often seen by a learning difficulties service. However, many professionals working in learning difficulties lack specific experience or training. Collaboration between services is needed to find effective ways of working with this emerging population.

2. Dimitra Kottorou1, Mrs
3. Christina Kamoutsli1, Mrs
4. Athina Georgitsi1, Mrs
5. Marilena Roumelioti1, Mrs, maril_1@yahoo.gr

In this study we present the letters that three children aged 8, 12 and 12 years respectively, wrote to their parents before attempting to commit suicide. Through these letters, the different characteristics of suicide attempts are examined with respect to different psychopathology profiles that emerge. These three cases were drawn from a larger sample of children and adolescents who were referred to our department after a suicide attempt during a nine-year period. A group of them were detected as being at high-risk for developing early-onset mood disorder and were followed for a period of 3 years.

All the clinical data collected within the 3-year follow-up are used for the study of the cases. Through the presentation of these letters and the study of the cases we have the opportunity to discuss the specific characteristics and differences within the spectrum of early-onset mood disorders.

3. Andrés Mauricio Rangel-Martínez-Villalba1, Dr., MD, arangel@unab.edu.co
4. Adalberto Campo-Arias2, Dr., MD

Background: Daily cigarette intake is associated with high morbidity and mortality in adults. This pattern of tobacco use is established during early adolescence. Furthermore, a lot of variables in Colombian adolescents have not been studied yet.

Objective: To establish the prevalence and associated factors daily cigarette smoking among middle and high school-students in Bucaramanga, Colombia.

Methods: A random sample of adolescent students completed an anonymous questionnaire asking about illegal and legal substance use, CAGE questionnaire, Center for Epidemiological Studies-Depression Scale, Francis Scale of Attitude Toward Christianity, Rosenberg Self-Esteem Scale, the module for antisocial personality of the questionnaire of the structured clinical interview for DSM-IV axis II diagnosis, and family APGAR. Logistical regression was used to control confounding variables.

Results: A total of 2,848 students participated in this research. The mean age was 14.4 years; 51.1% was female. The prevalence of occasional and daily cigarette smoking during the last month was 12.4% (95%CI; 11.2-13.7) and 4.6% (95%CI; 3.8-5.4) respectively. Daily cigarette smoking was associated with sibling substance consumption (OR=3.64; 95%CI 2.36-5.64), bad health perception (OR=3.46; 95%CI; 1.42-8.46), low self-esteem score (OR=1.88; 95%CI; 1.03-3.45) and alcohol dependence pattern (OR=3.74; 95%CI; 2.49-5.65).

Conclusions: One in 22 middle- and high-school student adolescents from Bucaramanga is a daily cigarette smoker. Daily cigarette smoking was associated with sibling substances consumers, bad health perception, alcohol dependence pattern, and low self-esteem score.

EATING AND WEIGHT DISORDERS IN AN ADOLESCENT RESIDENTIAL PSYCHIATRIC FACILITY

INSTITUTIONS
1. Rivendell Adolescent Unit, Sydney South Western Area health Service, Concord, Australia
2. University of Sydney, Discipline of Psychological Medicine, Sydney, Australia

AUTHORS
1. Janice D Russell¹,², Professor Doctor, MD FRACP FRANZCP, jrussell1@mail.usyd.edu.au
2. Rose Anderson¹,², MBBS MMed FRANZCP, Dr, rose.anderson@email.cs.nsw.gov.au
3. Robert Redwin¹,², Dr, MBBS MMed FRANZCP, robert.redwin@email.cs.nsw.gov.au

Eating and weight disorders most often have their onset in adolescence, are prevalent in this age group and constitute a major public health problem. Adolescents with eating and/or weight disorders not infrequently become psychiatric patients. The occurrence of eating and weight disorders in a residential psychiatric facility for adolescents who are receiving treatment for a variety of disorders including early psychosis, depression, anxiety disorders, attention deficit and autistic spectrum disorders is of major concern.

Aim/Objectives: To ascertain eating disorder diagnoses in day and residential patients of a residential adolescent treatment facility between March and June 2006

Methods: Seventeen patients were surveyed over a three-month period using EEE-C (Abraham and Lovell 2000), a computerised inventory for eating disorders and exercise. Patients were also weighed and measured.

Results: Only three out of 17 adolescents did not have an eating and/or a weight disorder. Diagnoses included purging and restricting anorexia nervosa, bulimia nervosa, EDNOS, binge eating and exercise disorder. Almost half the adolescents were overweight or obese.

Conclusions: Eating and weight disorders were present in the majority of adolescents surveyed. How these were addressed and measures aimed at prevention will be discussed along with data from a follow-up survey two years later.

Introduction: Adverse events during childhood and adolescence are believed to be related with adulthood psychopathology. Both axis 1 and 2 psychiatric disorders have been found to be associated with past adverse events. The aim of this study is to find the rate of childhood adverse events in a cohort of psychiatric inpatients and investigate the correlation between the type of adverse event and variety of psychiatric diagnosis.

Methods
Records of 1105 patient, who have been hospitalized in psychiatry inpatient service of Gazi University Hospital between years of 2001 and 2006, were searched retrospectively. 211 patients (19.09 %) who have experienced physical, sexual and emotional abuse before the age of 16 were included in the study.

Results
Numbers of female and male patients of the sample were 136 and 72 respectively. 64.5% of these patients (n=138) have experienced one adverse event whereas 34.6% patients (n=73) have experienced multiple adverse events. There was no statistically significant difference between the type of adverse events and axis 1 and 2 diagnosis of the patients (p=0.64 for axis 1; p=0.76 for axis 2). Patients diagnosed with at least one axis II disorder had significantly higher number of childhood adverse event than patients without axis II disorder.

Discussion
One of the most considerable outcomes of this study is the high frequency of trauma history in psychiatric inpatients. Especially patients with personality disorders have reported significantly higher childhood adverse events.

5. Romina Kuyumcuoglu²

According to prospective studies; hyperactivity, behavioral problems and substance use were found to be the predictors of delinquent behaviors in child and adolescence. Comparing to the non-delinquent youngsters, the probability of having psychiatric disorders is three times more for delinquent ones. However; psychiatric disorder ratios are changing according to the socio-demographical features and to the prevalence of the disorder in the general population of the countries where researches have been conducted. For this reason, finding an answer to the question of "Can delinquency be prevented?" is very important. In order to do this, we are conducting a research with child and adolescence who are staying at "Agaci Care and Rehabilitation Center" because of their delinquent behaviors. Since, research is in progress results are not obtained yet. However; according to the initial findings ADHD, depression and anxiety disorders are common in this sample. Another important finding is that by the effect of ADHD, education is interrupted. With the lack of social support being away from the school leads these children and adolescents to have trouble with laws. When the results obtained, it will be clearer how delinquent behavior can be prevented.

AN EPIDEMIOLOGICAL STUDY OF BULLYING IN SCHOOL CHILDREN

INSTITUTIONS
1. PGIMS, Rohtak, Department of Psychiatry, Rohtak, India

AUTHORS
1. Sujata Sethi¹, Dr., MD, reachsujatasethi@gmail.com
2. Subhash Chander Bhargava¹, Dr., MD, b-subhash@indiatimes.com
3. Rajat Setiya¹, Dr., MD

Aims: To investigate the prevalence of bullying in school children and to study the socio-demographic correlates of bullies and victims.

Method: The students of grades 7 and 8 constituted the study sample. The schools—one private and one public were selected randomly. The Korean-Peer Nomination Inventory (KPNI) scale was used to identify the bullies and victims. The data obtained were analyzed using SPSS Version. 10.0.

Result: The prevalence of school bullying was 43.5% Bullying behavior was categorized as follows: victims only 19%, perpetrators only 18.4% and victim-perpetrators 6.2%. Boys outnumbered girls in bullying in all 3 categories though the difference was statistically insignificant. Most of the perpetrators belonged to high family income group. Education level of the fathers of the perpetrators (in private school only) was found to be significantly correlated. Their fathers were more likely to have completed the college level.

Conclusions: The study shows that bullying behavior is highly prevalent in school children. Most of the socio-demographic variables did not correlate with the bullying. The study indicates the need for comprehensive remedial plan at the level of school, parents and law enforcing agencies.

SOCIAL PHOBIA: A STUDY OF ITS PREVALENCE IN TWO SCHOOLS IN PORTO ALEGRE, BRAZIL.

INSTITUTIONS
1. Fundação Faculdade Federal de Ciências Médicas of Porto Alegre, Psychiatry and Forensic Medicine, Porto Alegre, Brazil

AUTHORS
1. Gabrielly Cruvinel Fernandes, Mrs., MD, gabrielly@terra.com.br
2. Mauro Barbosa Terra, Mr., PhD, mabarte@portoweb.com.br

Objectives: This study reports the prevalence and impact of social phobia on education in a sample of adolescents of one public and one private school in the city of Porto Alegre, RS, Brazil.

Methods: The Social Phobia Inventory (SPIN) was administered to 525 students of primary and high school, of both genders, but 32 students were excluded from the study due to incomplete answers. A questionnaire to observe sociodemographic characteristics of the sample was also used.

Results: According to the SPIN, 114 of 493 (23.12%) students obtained scores equal to or greater than 19 points. Girls tended to show a greater frequency of social anxiety disorder when compared to boys (p=0.053). Social phobia was not associated with a higher number of repeating students.

Conclusion: Social phobia symptoms are common among teenagers and, due to its chronic course, may result in severe impairments. Therefore, early identification and treatment of such disorder is extremely important.

Keywords: Social phobia. Adolescents. Prevalence. Impairment.

FREQUENCY OF ADHD IN ADULTS MEXICAN SAMPLE WITH SUBSTANCE ABUSE DISORDERS

INSTITUTIONS
1. National Institute of Pediatrics, Mental Health, DF, Mexico
2. National Institute of Psychiatry, DF, Mexico

AUTHORS
1. Mirna A. Trancoso, Dra., MD, mirna_trancoso@yahoo.com.mx
2. Diana Molina, Dra., MD
3. Ricardo Nanni, Dr., MD

Objective: To describe frequency of ADHD in adults with substance abuse disorders (SAD) in a Mexican Sample.

Method: Assessment of 85 adults with SAD. ADHD diagnosis was done using OMS rating Scale Adults ADHD, Wender Utah Scale (WURS) and Weiss and Murray items (WM).

Results: Sample with SAD was male 60% and female 40%. The rate of ADHD was of 54.1 %, for retrospective childhood diagnosis we found 68.2% were positive for ADHD, of them 62 % was male and 38 % female. Most frequent psychiatric diagnosis was Depression (89.4%), Anxiety Disorders (40%), Eating Disorders (22.4%), and Bipolar Disorder (15.3%). Antisocial Personality was 35.31%, and 29.4 report moderate suicidal risk. Most frequent Substance Abuse was Cannabis (92.9%), alcohol (82.3%), tobacco (48.2%), and cocaine (48%) None of patients with ADHD had ever been diagnosed and treated in childhood.

Conclusions: Frequency ADHD was similar to international findings. ADHD sample had a statistical difference in cocaine abuse (p=0.03) and cannabis (p= 0.001). Adults ADHD had difference in difficulty managing money, completing housework or being on time (p= 0.01) and trouble living with others (p= 0.006).

PSYCHO-EDUCATION IN AUTISM SPECTRUM DISORDERS

INSTITUTIONS
1. Vincent van Gogh Institute for Psychiatry, Clinical Research, Venray, The Netherlands

AUTHORS
1. Wim Verbeeck¹, Dr., MD, WVerbeeck@ggzvn.nl
2. Iris Bloemen¹, Mrs, MA, IBloemen@ggzvn.nl
3. Rob van Tienen¹, Mr., MA, Rvntienen@ggzvn.nl
4. Siegfried Tuinier¹, Dr., MD, PhD, stuinier486@freeler.nl

Aims
Psycho-education is considered to be a cornerstone in the management of individuals with a psychiatric disorder. It is assumed that the awareness and insight into the illness plays a role in the recognition and experiencing of symptoms, the ability to accept help, the ability to adapt to the illness, therapeutic compliance, and prognosis. Doubts have been put forward, whether these tenets apply in a similar fashion to chronic psychiatric conditions. It has been reported amongst psychotic patients, that insight into the illness is correlated with less emotional wellbeing. Research on the impact of psycho-education on patients with an Autism Spectrum Disorder (ASD) is scarce.

Methods
A pilot study was started to ascertain the efficacy of psycho-education in ten young adults with ASD. They participated in a structured psycho-educational program, consisting of eight sessions of two hours. The Harter Self-Perception Profile for Adolescents and The Rosenberg Self-Esteem Scale were administered at baseline and after the last session. The former scale is a self-administered scale measuring the adolescent's perceived competence in various domains as well as there sense of general self-worth.

Results
Scores on the Rosenberg scale increased about 25%. Scores on the Harter Profile differed dependent on the domain measured. Self-worth increased as well as the perceived capacity for friendship. Measures that implied social interaction did not.

Conclusion
The results of this pilot study do not suggest detrimental effects of psycho-education. The sample is too small to prove an increased sense of well being.

ACCESSIBLE MEDICATION INFORMATION FOR PEOPLE WITH INTELLIGENT DISABILITIES

INSTITUTIONS
1. University of Birmingham, Department of Psychiatry, Birmingham, United Kingdom

AUTHORS
1. Gemma L Unwin¹, Miss, BSc, G.L.Unwin@bham.ac.uk
2. Shoumitro Deb¹, Professor, MBBS, FRCPsych, MD, S.Deb@bham.ac.uk

Aims/Objectives
To provide resources to assist clinicians in adhering to a national (UK) clinical guideline on the use of medication for behaviour problems in adults with intellectual disabilities (ID). To provide people with ID accessible information about medications. To work in collaboration with people with ID.

Methods
The guideline recommends that clinicians provide service users with information about their medication to take away. Initially, an expert who has worked on accessible information designed a template for the 35 medication information leaflets. The individual leaflets were then drafted following this template, taking specific information from the British National Formulary. The leaflets used easy words, short sentences, large font size and pictures to help convey the information. The leaflets were then translated into audio versions. Two groups of people with ID advised on the project. A steering group of pharmacists and psychiatrists also gave advice on the content of the leaflets.

Results
The resources provide accessible audio and visual information relating to medications that are used to manage behaviour problems. They include information on medication names, side effects, when and how the medication should be taken and where further advice can be sought. All the resources were uploaded to the project website and are freely available to download and distribute. CDs containing the information were also produced.

Conclusion
It is important that people with ID are given information in a way that they understand, particularly in relation to medication. It is essential that people with ID are consulted when developing such information.

PEDIATRIC HOSPITALIZATION IN SUICIDAL ATTEMPTS

INSTITUTIONS
1. University of Concepcion, Psychiatry and Mental Health, Concepcion, Chile
2. University of Concepcion, Psychology, Concepcion, Chile

AUTHORS
1. Mario Valdivia¹, Dr., MD, mvaldivi@udec.cl
2. Daniel Silva¹, Mr, dansilva@udec.cl
3. Felix Cova², Dr., PhD, fecova@udec.cl
4. Silverio Torres¹, Mr

Aims
We describe the biodemographic characteristics of all the children that were admitted for suicidal attempt in the pediatric unit of Concepcion General hospital between October 1995-September 2003, and the characteristics of their attempts.

Objectives
1. To describe the sociodemographics characteristics of the suicidal attempters hospitalized in the pediatrics services.
2. To describe the clinical characteristics of those attempters.
3. To describe the characteristics of their attempts.

Methods
All patients admitted during the period were included in the study. The patients and their families were assessed by child psychiatrist and their medical files were reviewed. The information was registered in a special record and then descriptively analyzed.

Results
128 children were admitted; their mean age was 13.04 years (6-15 years), 85.9% were female, 43.0% lived with both parents, 61.7% had at least a relative with a psychiatric disorder, and 56.3% reported some kind of domestic violence.

The most common psychiatric diagnostics of the attempters were depressive disorders (44.5%), and abnormal personality traits (31.3%).

Most of the suicide attempts took place in the children’s home (78.1%), they were in October (beginning of spring) in 14.1% and in December (end of the school year) in 13.3% of the cases. Most of them were without planning (57.8%), and after a precipitant situation (84.4%), medicament overdose was the most commonly used method (83.6%) and intensive care unit was required only in 20.3% of the cases.

Conclusions
The study of the group of children that begins early in their lives with suicidal behavior is of the utmost importance in order to design early intervention and prevention programs.

ANALOGIES BETWEEN PUNISHMENT AND OBSESSION-COMULSION: EVIDENCES OF A SOCIAL APPRENTICESHIP

INSTITUTIONS
1. Centro de investigación, difusion y promocion de la libertad interior (cipli), research, Trujillo, Peru

AUTHORS
1. Juan Miguel Vargas Ponciano¹, Dr., PhD., chrisvar009@gmail.com

Objective: Demonstrate that Mental Illness, as aberrant process, is not a genetic disease.

Method: Analysis and record of all those animus states produced in the real I search, during 3 decades.

Results:
Unexpected assault of paternal dispositions and coercive ideas or impulses, attacking against the Being, like they both share: Their repeated persistence, initial rejection, ignorance of their origin, to ignore their real premeditation, to interrupt the homeostasis, not to represent an intrinsic need, not to execute it will increase the contradictions; try for ignoring it, suppressing it, neutralizing it without result; alternative does not exist before these, because they are incisive and vertical; any adopted attitude will not avoid such a coaction; to execute immediately against the will; to produce annoyance, alienation and loss of control; environment disconnection, a dual feeling appearance. Consciousness of: impotence, not to have the necessary weapon to revert it and that, of such a conflict, will leave loser. This mechanical repetition, with evident vexation, originating a dead time (Non-Being), it will make abort the existence, of the Being, in emptiness, toward future avoidance.

Conclusion: This demonstrates that 'Mental Illness' comes from that imperfect relation among parents and children; since both events are essentially identical.

ADHD IN ADULTS: CO-MORBIDITY AND AETIOLOGY

INSTITUTIONS
1. Vincent van Gogh Institute for Psychiatry, Clinical Research, Venray, The Netherlands

AUTHORS
1. Wim Verbeeck1, Dr., MD, WVerbeeck@ggzn.nl
2. Siegfried Tuinier1, Dr., PhD, stuinier486@freeler.nl

Aims
Attention Deficit and Hyperactivity /Impulsivity Disorder (ADHD) is a neuropsychiatric condition that affects about 1 % of the adult population. Approximately 70 % of patients with ADHD have additional disorders, making co-morbidity the rule. Apart from that ADHD is co-morbid in a variety of other disorders, including psychoses and mental retardation. This situation severely hampers research into genetic aetiologies. Originally co-morbidity was not conceived to signify that the patient had several disorders, but to document the whole symptomatic syndrome in a patient.

Methods
Two hundred adult patients with ADHD are examined for co-morbid conditions with semi-structured interviews, collateral information and an extensive neuropsychological battery. Furthermore an analysis is performed of research into the genetic aetiology of ADHD and especially the use of inclusion and exclusion criteria in this research.

Results
The pattern of co-morbidity corresponds to a large extent with similar studies. The research about the genetics of ADHD is severely compromised by co-morbidity, the inclusion of heterogeneous samples and the implicit conception that ADHD is a homogenous disorder instead of a behavioural syndrome with a variety of aetiologies. This state of affairs is comparable to that about the genetic aetiology of schizophrenia and autism.

Conclusion
The current diagnostic fashions itself are the cause of the inconclusive results of the research into the genetic aetiology of ADHD.

MENTAL ILLNESS: REPETITION AND STYLIZATION OF A LEARNED CONDITIONAL PATTERN

INSTITUTIONS
1. Centro de investigación, difusión y promoción de la libertad interior (Cipli), Costa Rica

AUTHORS
1. Serulio Winar1, DR

Objective: Demonstrate that ‘Mental Illness’ has as a central nucleus the mechanical exercising of a pattern learned at home.

Method: Planned introspection and meticulous evolved record of all internal conflicts triggered after the tireless search of the I, during 30 years.

Results: The Human Being, during fetal life, exercising only material laws is being fused to the Cosmos, with universal objectives; after the delivery, executing what please to his progenitors, he keeps adapted to group: I. Valid this at home and reinforced in the society Man learns that, over his intrinsic requirements and natural accomplishment, his progenitor is as principal element, to whom he has to satisfy and to be pending on his requirements to deserve a recompense and avoid a punishment: Social Law.

Conclusion: Search of the liberty unmufflely puts in evidence the learned mechanization, preventing non-adaptation. However, if that automatism is executed with a particular ‘element’ occupying progenitor position, such aberrant supplantation with later stylization, inescapably will guide to exercise answers tend to effect change in the form and behavior of ‘this’, the same as he did as with the aggressive progenitor, his impositions and conditioned stimuli to avoid a punishment, only now he is consciousness of his automatism.

MDR1 POLYMORPHISM ASSOCIATED WITH RESPONSES AND SIDE-EFFECTS OF OROS-METHYLPHENIDATE IN CHILDREN AND ADOLESCENTS WITH ADHD

INSTITUTIONS
1. Pochon CHA University College of Medicine, Department of psychiatry, Seongnam, Republic of Korea
2. Hallym University College of medicine, Department of psychiatry, Chuncheon, Republic of Korea
3. Yonsei University College of Medicine, Department of pharmacology, Seoul, Republic of Korea

AUTHORS
1. Ki-Hwan Yook¹, Mr., MD, PhD, chachacha97@hanmail.net
2. Hyun Ju Hong², Mrs., MD, PhD, hongdr@chol.com
3. Sung Hee Lee³, Mr., MD, egohigher@yunc.yonsei.ac.kr
4. Min Goo Lee⁴, Mr., MD, PhD, mlee@yumc.yonsei.ac.kr

Objectives: We investigated the association between five SNPs of multidrug resistant protein 1 (MDR1, ABCB1) and responses/side effects of OROS-methylphenidate (OROS-MPH) treatment in children and adolescents with attention deficit/hyperactivity disorder (ADHD).

Methods: 123 children and adolescents with ADHD who were treated with OROS-MPH were analyzed with 5 SNPs of MDR1 gene. The SNPs were compared between subjects and normal controls (N=100). Subjects were grouped into Responders and Non-Responders according to their reduction rate of K-ARS scores at 4th week of OROS-MPH treatment. The scores of side effects of OROS-MPH were compared with genotypes of MDR1.

Results: There were no differences statistically in age, sex ratio, ADHD rating scale scores at baseline and OROS-MPH doses at 1st and 8th week between responders and non-responders. All the 5 SNPs were in Hardy-Weinberg equilibrium and had no significant difference in the genotype frequencies of subjects as compared with normal Korean controls (N=100). The LD blocks and its associated values are listed. One promoter SNP, g.-1459G>a, was associated with the responder group at 4th week. The a alleles of this SNP found more in responder group than in non-responder. In haplotype analyses, the second haplotype composed of 5 SNP was also associated with non-responder group. In addition, c.2677G>T was associated with the increase of side effects of OROS-MPH, especially in the appetite category.

Conclusion: Our results suggest that subjects who have A allele of g.-1459G>A without TT genotype of c.2677G>T are likely to have good response without serious side effects of OROS-methylphenidate.

STUDY OF FACTORS AFFECTING HEALTHY LIFE BEHAVIORS OF TURKISH ELDERS

INSTITUTIONS
1. Ege University School of Nursing, Department Of Psychiatric Nursing, Izmir, Turkey
2. Ege University School of Nursing, Izmir, Turkey

AUTHORS
1. Ayça Gürkan¹, Dr., PhD, ayca.gurkan@gmail.com
2. Aysun Babacan Gümüş¹, Dr., PhD, aysungumus@hotmail.com
3. Armadan Ersoy¹, Mrs., armaganersoy_1983@hotmail.com

Objectives: Being elderly creates various problems due to physical, social, economical and cultural changes (1,2). The purpose of this study was to study the factors affecting healthy life behaviors of elders.

Method: The study was carried out in a rural rest home located in Usak, Turkey, between January 2007 and February 2007. The sample consisted of 150 elders, selected by basic random sampling method. The data were collected by introductory information Form and The Healthy Life Behavior Scale. ANOVA, t test and Tukey HSD test were used for analysis of data.

Results: The mean age of the elders was 70.69 ± 6.09. It has been determined that there is a significant difference in the Healthy Life Behavior Scale mean score of elders according to age (F=3.460, p<0.05), marital status (F=11.832, p<0.01), education level (F=5.139, p<0.01), working condition (t=3.005, p<0.01), the frequency of seeing their children (F=5.573, p<0.01) and also the frequency of meeting their relatives (F=5.982, p<0.01).

Conclusion: As a result, it has been determined that the healthy life behaviors of the elders who are above 75, illiterate, unemployed and who live alone and never see any of their children or relatives are to be in lower level.

4. Knut Engedal¹³, Dr., MD, PhD, knut.engedal@aldringoghelse.no

Aim/Objective: Depression is one of the most prevalent psychiatric symptoms among patients with dementia and is associated with negative outcomes. The aim of the study is to analyze the prevalence of depression and its correlates in a nursing home sample.

Methods: A sample of 1,159 randomly selected nursing home patients was assessed with the Cornell Scale, the Clinical Dementia Rating Scale (CDR) and Lawton’s Scale for activities of daily living. Additionally, information was collected from the patients’ records. We considered a cut-off ≥ 7 in the Cornell Scale as clinically significant depressive symptoms, and analyzed differences between patients with and without dementia of various degrees. A multiple stepwise logistic regression analysis was performed with depression as the dependent variable.

Results: The prevalence of significant depressive symptoms was 31.2%. In bivariate analyses patients with depression were more functionally (p<0.001) and cognitively impaired (p<0.001), used more drugs (p<0.001), antipsychotics (p<0.001), anxiolytics (p<0.001), hypnotics (p=0.004) and antidepressants (p=0.001), and had worse physical health (p<0.001). In the multivariate logistic regression analysis the following variables were of significance: CDR score (p<0.001), use of anxiolytics (p<0.001), total number of drugs (p=0.004), use of sedatives (p<0.012) and use of antipsychotics (p=0.02).

Conclusion: Prevalence of depression in Norwegian nursing home patients is high. Depression was associated with cognitive impairment, use of anxiolytics, number of drugs, sedatives and antipsychotics, but not with use of antidepressants.

2. Matthias Weisbrod2,3, prof., MD, Matthias.Weisbrod@kkl.srh.de
3. Thomas Christine4, Dr., MD, mail@christinethomas.de

Objectives: Patients with Alzheimer’s disease present characteristic memory deficits. So far, no direct parameter has been described to image a possible faster decay of cortical sensory short-term memory traces. However, we recently described that modality-specific cortical areas show prolonged activation after short stimuli (N700 event-related potential component) in healthy adults (see references). We wanted to test whether N700 would be a suitable marker to image a faster decay of sensory stimulus-postprocessing in Alzheimer’s disease.

Methods: We analyzed ultra-late stimulus post-processing (sensory memory traces) as reflected by the N700 ERP-component after paired auditory clicks in 17 subjects with Alzheimer’s disease (AD) and 17 age-matched controls. Subjects passively heard the stimuli while watching a silent video.

Results: While earlier auditory evoked potentials were not reduced, N700 decayed significantly earlier in subjects with AD (400-500ms).

Dipole source analysis (BESA) indicated reduced activity from a generator in the auditory cortex in the temporal lobe.

Conclusions: The N700 ERP-component takes advantage of the high time-resolution of multichannel EEG. It is a promising marker to image a faster decay of automatic traces in the sensory cortex in Alzheimer’s disease. Further studies in other modalities should be undertaken to establish whether a faster decay of sensory memory traces is a replicable and general phenomenon in AD.

DEMENTIA AND STIGMA: PUBLIC BELIEFS ABOUT REJECTION AND RISK OF VIOLENCE

INSTITUTIONS
1. UNIFESP, Psychiatry, São Paulo, Brazil

AUTHORS
1. Sergio L Blay1, Dr., MD, PhD, blay@uol.com.br
2. Erica T.P. Peluso1, PhD

Aim: To assess the frequency of stigma and the risk of violence within a general population of the city of São Paulo, Brazil, when a vignette depicting an Alzheimer’s Disease (AD) case is shown to the selected sample.

Method: Cross sectional population-based random sample of 500 household residents aged 18 years and over were examined in Sao Paulo. Instruments were a case vignette depicting an Alzheimer Disease (DSM-IV) and a structured questionnaire investigating stigma, negative conceptions and the risk of violence.

Results: Stigma and negative conception against Alzheimer disease was identified by 43% of the interviewees. Results also showed that 35% of the respondents consider that people close to an Alzheimer disease patient will consider keeping a distance of such patient. The risk of a violent behavior was identified by 41% of the sample. However this figure is sharply reduced if the population is informed that patient is receiving appropriate treatment. Logistic regression showed no factors affecting responses on stigma and violence.

Conclusion: Stigma and the risk of violence are clearly present in the general population’s perception in relation to a case vignette depicting an AD case. No sociodemographic variable is associated to stigma against AD patients.

RETHINKING RETROGRADE AMNESIA: THE ROLE OF MEDIAL TEMPORAL, LATERAL TEMPORAL AND FRONTAL PATHOLOGY

INSTITUTIONS
1. Anglia Ruskin University, Department of Psychology, Cambridge, United Kingdom
2. University of Cambridge, Experimental Psychology, Cambridge, United Kingdom
3. Kings College London, Institute of Psychiatry, University Department of Psychiatry, London, United Kingdom

AUTHORS
1. Peter Bright1,2, Dr, PhD, pbright@cs1.psychol.cam.ac.uk
2. Michael Kopelman3, Professor

Objectives and Methods
There is considerable controversy concerning the theoretical basis of retrograde amnesia. We compare medial temporal, medial plus lateral temporal, and frontal lesion patients on a new autobiographical memory task and measures of the more semantic aspects of memory (famous faces and news events). We also present a more detailed analysis comparing individual patients with quantified pathology restricted to specific critical brain structures.

Results
The main group study revealed the following: Temporal pathology: Only those patients with damage extending beyond medial temporal cortex into lateral temporal regions showed severe impairment on free recall remote memory tasks, and this held for both the autobiographical and more semantic memory tests. Frontal pathology: We found no clear evidence for remote memory impairment in the frontal group on any task. However, correlational analyses indicated significant correlations between frontal lobe volumes and recall performance on semantic (but not episodic) tasks. These findings, in the context of further detailed analysis of individual cases, raise the possibility that, although medial and temporal regions may form part of a distributed neural network subserving memory retrieval, damage needs to be quite extensive and exceed a certain critical volume before a significant remote memory impairment can be observed.

Conclusions
The findings do not offer unequivocal support for either consolidation or multiple trace theory, but suggest that a widely distributed network of regions underlies the retrieval of past memories, and that the extent of lateral temporal involvement is critical to the emergence of a severe remote memory impairment.

Objective: To explore the prevalence and subtypes of depression in patients with Alzheimer’s disease (AD), vascular dementia (VaD), or undifferentiated dementia (UD).

Methods: Analysis of subtypes of depression was conducted on 6,440 patients 60 years or older with dementia (2,947 AD, 725 VaD and 2768 with UD) from the Integrated Healthcare Information Services (IH CIS), a National Managed Care Benchmark Database database, identified from January 1, 2001 to December 31, 2001. Sub-types of depression, AD, VaD and UD were diagnosed using ICD-9 criteria.

Results: The prevalence rate of depressive disorders was 27.41% in all patients with dementia independent of the dementia subtype. The prevalence of depressive disorders was much higher in the VaD group (44.14%) and UD group (32.48%) compared to AD group (18.53%). Compare with AD and UD, VaD patients had significantly higher prevalence in arteriosclerotic dementia, depressive disorder NOS, major depressive disorder single and recurrent episodes and neurotic depression (p<0.01). Adjustment disorder, presenile and dementia senile with depression were significantly more common in UD patients, whereas depressive psychosis was similar in all dementias types. AD patients had the lowest prevalence in all subtypes of depression.

Conclusions: This study supports that depression is more prevalent in VaD compared to UD and AD and also provide indicators to the clinician for further evaluation of depression in different dementia subtypes.

In the broadest sense the dementia can be characterized as acquired conditions, which are appearing after final developments of intellectual functions. All dementias toward dominant source of etiopathogenesis mechanism can be divided into subcortical, cortical and mixed. Appearance of depressive phenomenology is a significant characteristic of subcortical dementias, so that represents an important differential-diagnostically dilemmas toward unipolar depressive disorders. In the group of subcortical dementias an important place takes certain kinds of vascular dementia, among is also Subcortical Arteriosclerotic Encephalopathy - MorbusBinswanger. This dementia, toward original review by Otto Binswanger, characterizes gradual, slowly progressive mental deterioration and changes in white mass with secondary ventricular dilatation. Before its introducing, MRI was considered as extremely uncommon, neuropathological entities. Benett and fellows are suggesting clinical and radiological criterions for a diagnose setting. Basic cognitive profile characteristics of this dementia are memory disorders and disexecutive syndrome.

In our research we are representing a development of cognitive and depressive phenomenology to 70-years-old woman patient, hospitalized in our hospital during 2007. Because of exacerbation depressive syndrome.

Key words: depressive syndrome, vascular dementia, Morbus Binswanger.

Objective: To determine differences between narcissistic personality disorder and no personality disorder as regards the following variables: suicide attempt, behavioral and psychological symptoms of dementia, psychotic episode, diagnostic assessment, substance abuse, depression and suicide ideas, in older patients with dementia.

Material and methods: This is a comparative, prospective, observational, transversal, single blind study

Results: We studied 67 inpatients with dementia. Statistical significant associations were found between narcissistic personality disorder and suicide attempt (p=0.022;OR;IC) and narcissistic personality disorder and suicide ideas (p=0.023;OR;IC)

Discussion: In patients with early dementia with perception of their deterioration narcissism and hate of ageing plays a crucial role. There seems to be an association between narcissistic personality disorder and suicide ideas and attempts in patients with dementia that should be taken into account to prevent suicide in older age not always related to depression.

In recent years functioning of glutamate system in Alzheimer’s disease (AD) has been extensively investigated. Glutamate is an excitatory neurotransmitter and neurotoxin that has the potential to destroy neurons. It was well documented the key role of glutamate in mechanisms of neuronal degeneration in AD. The study of antibodies to glutamate is important for understanding the mechanisms of neurodegeneration in AD and the development of therapeutical treatments.

The aim of present study was to determine the level of serum glutamate antibodies in modified solid phase immunoenzyme assay (ELISA) in patients with AD. The study included 41 female patients with AD and 30 mentally healthy women of the same mean age (81.0±7.0). The diagnosis of AD was made in accordance with the criteria of the National Institute of Neurological and Communicative Disorders and Stroke (NINCDS) and AD and Related Disorders Association (ADRA). In some cases brain Computer-Tomography was employed. In blood sera of AD patients we found significant higher levels of glutamate autoantibodies compared to elderly controls. Distinctions in the level of glutamate antibodies were revealed at early and late onset of AD (1,3±0,08, 1,9±0,1; p <0,05). Moderate and severe alterations in cognitive function in AD patients correlated with high levels of glutamate antibodies. We suggest that glutamate antibodies can play the important role in protective mechanisms of neurodegeneration in AD. Glutamate antibodies may be used as neuroimmune marker in selecting the clinical and therapeutical strategies for AD.

It is generally accepted that the term, Phantom boarders symptom (PBS) was introduced by Rowan EL, a delusion occurring in the elderly, with or without dementia, in which the patients believe that someone uninvited is living in their homes. An old woman’s nightly phone calls of the police department complaining of loud noise and partying upstairs, or hippies in the attic, making loud conversation and music. These phantom boarders activities were not deliberately annoying the patients. These delusions and congruent hallucinat- ion occurred without other evidence of thought disorder, affective disturbance, or organicity and therefore may be a subset of late paraphrenia. PBS in this condition, is basically persecutory delusion. PB move into the house from external world, often associated with delusion of theft. Recently Terada S et al used a term, phantom intruder delusion, which clearly describes this characteristics. On the other hand, there is another type of PBS. Boarders were old family members and relatives, late father, mother, grand father, grand mother, nephews and nieces. They were not uninvited persons, but very old trustworthy persons never did nuisance. The patient showed no hostility behavior. They appeared willing to take care of these boarders, preparing meals or making beds for them, especially in cases of children. These may be referred as phantom relatives. These phantom relatives were much more popular in Japan and already described in Japanese literature. The difference and similarity will be discussed in terms of genesis of these PBS.

NURSING CONSULTATION FOR ALZHEIMER DISEASE PATIENTS CAREGIVERS: ONE YEAR EXPERIENCE AT PSYCHOGERIATRICS

INSTITUTIONS
1. Hospital de Magalhães Lemos, Serviço de Psicogeriatria, Porto, Portugal

AUTHORS
1. António José Giro¹, Mr., ajosegir@netcabo.pt

Alzheimer disease patients caregivers burnout is expected just from the beginning of illness process. That's why give them information about disease and its development as well as to teach them how to deal with all the changes in patients behavior is part of the program of our Service for patients with Alzheimer disease.

Nursing consultation for caregivers is where caregivers can learn more about Alzheimer disease and its consequences on daily living for the patient and family. They can also learn what to do and how to do it in order to protect and stimulate them.

Nursing consultation is also the site where caregivers can ask questions and where they can talk about their fears. Our first objective was to study the profile (caregiver's demographic characteristics and satisfaction with life) and the care burden in caregivers of patients with Alzheimer disease.

The second objective was to evaluate caregiver's satisfaction with nursing consultation and its impact: if it was useful and helpful for them.

The caregiver's profile was assessed by a non-structured questionnaire and Satisfaction With Life Scale (SWLS) (Diener et al., 1985) and the care burden was evaluated by Zarit Burden Interview (Zarit, 1983). Patients were moreover assessed with Barthel Index (Barthel, 1965) and the Lawton and Brody's Index (Lawton, 1969).

Functional scales were applied to patients or to caregivers during an interview.

THE SLEEP PATTERN CHARACTERISTICS AND AFFECTING FACTORS OF TURKISH ELDERS

INSTITUTIONS
1. Ege University School of Nursing, Psychiatric Nursing, Izmir, Turkey

AUTHORS
1. Esra Engin¹, Dr., PhD, esraengin@yahoo.co.uk
2. Aysun Babacan Gümüş¹, Dr., PhD, aysungumus@hotmail.com
3. Gönül Özgür¹, Dr., PhD, gonul.ozgur@ege.edu.tr

Objectives: Elders have difficulties physically, socially and physiologically (1,2). This study was conducted to investigation of factors affecting sleep pattern characteristics of Turkish elders.

Method: The study was carried out between December 2007 and January 2008. The sample of the study was composed of 132 elders residing in Izmir Gürçesme Rest Home. The data were collected by Introductory Information Form and Sleep Pattern Characteristics Form (Cronbach alpha = 0.67) developed by researchers in line with the related literature (2). The data were analyzed by ANOVA, t test and Scheffe test.

Results: The mean age of the elders was 75.79 ± 7.62. It has been calculated that there is a significant difference between the sleep pattern characteristics mean score of the elders and gender (t=4.643, p<0.01), physical health perception (F=9.045, p<0.01), sleep quality perception (F=63.540, p<0.01), the situation of residing in rest home voluntarily (t=-2.468, p<0.05) and the status of using a drug for physical problems (t=2.776, p<0.05).

Conclusion: As a result, it has been determined that the sleep pattern characteristics of the elder women who consider their physical and psychological health and sleep quality as bad and who don't reside in rest home voluntarily and take physical drugs are to be in a bad condition.

3. Ertuğrul Saatçi  
4. Erol Başar

Aims/Objectives: As a new evaluation in a series of measurements in Alzheimer patients (1), event related coherence of patients with Alzheimer type of dementia (AD) was analyzed by using a visual oddball paradigm. Method: A total of 22 mild probable AD subjects were compared to a group of healthy controls consisting from 20 age-, gender-, and education-matched subjects. AD group was divided into the untreated (n=11) and those treated with cholinesterase inhibitor (n=11). EEG responses were recorded from 13 scalp electrodes. Results: Higher coherence values in the theta frequency range at F3-P3 were found between control group and both of the AD groups by using One-way ANOVA analysis (between groups, p=0.010) (treated vs control p=0.014; untreated vs control p=0.009; Post-hoc LSD test). Cholinesterase inhibitors did not have significant effect on theta coherence values. Conclusion: Our findings imply that left fronto-parietal connections are highly affected by AD pathology occurring primarily in parietal regions at early stages. We also have the hope that analysis of brain oscillations and evoked coherences can be useful in diagnosis of AD.

5. Shuyue Zhao

Aim: To investigate the effect serum IL-1β in Alzheimer’s disease of aging rats. Methods: 20 rats were divided into two groups with 10 in each, one was model, while the other group with compare. The model rats were treated with D-galactose and AlCl3 to establish the AD animal model. D-galactose and AlCl3 were given through intraperitoneal route for 90 days. Another 10 rats without any intervention were as normal controls. After the 90th day, the water maze test was on the AD model rats. At the last test day, the animals were killed and the expression of serum IL-1β was measured with enzyme linded immunosorbent assay (ELISA).

Results: Normal controls had shorter latency (P < 0.01) and less error times (P < 0.05) in water maze test compared with those in AD model group. Furthermore, AD model group serum IL-1β (38.38±5.49), normal controls of serum IL-1β (23.96±5.39) (P < 0.05).

Conclusion: Serum IL-1β increased that should be important factors in the neurodegeneration process associated with AD and it should significantly contribute to the pathogenesis of AD.

2. Ammar Natalwala
3. Rahul Potluri1
4. Hardeep Uppal1
5. Parth Narendran2

Objective: Dementias are major causes of mortality. The mortality rates of different types of dementia may vary due to the variable influences of different risk factors. Consequently, the present study investigates the influence of age, gender, ethnicity, length of stay and co-morbidity on the risk of mortality after first hospital admissions.

Methods: During 2002-2007, 505 patients with Alzheimer’s disease, 283 with vascular dementia, 1773 with mixed dementia and 53123 age-matched controls were admitted to University Hospital Birmingham NHS Trust. The influence of risk factors on mortality was examined using multivariate statistics including Cox regression analysis.

Results: Mortality was increased in all types of dementia compared to controls. The relevance of risk factors on mortality was significantly different between the three types of dementia, e.g. co-morbidity being more relevant in subjects with vascular types of dementia.

Conclusions: The relevance of risk factors of mortality varies for different types of dementia. Prevention of mortality in dementia may be more efficient if interventions were specifically directed towards the individual types of dementia.

4. Katrin Pottrich1, Dr., PhD
5. Annett Werner2, Dr., PhD
6. Ruediger von Kummer2, Professor Dr., MD

The purpose of the present study was to compare the neural correlates associated with content (episodic versus semantic) and remoteness (recent versus remote) of memories in patients with early AD and age-matched controls. We performed fMRI in 14 healthy elderly (mean age 60.5 years, SD 5.7) and 14 patients with early AD (mean age 61.5 years, SD 7.4, MMSE mean 25, SD 2.1) and analysed neural activity related to memory content and remoteness (remote events from the age of 5-15 years, recent events from the last five years). The stimuli used during the fMRI study were based on autobiographical episodic memory items that included recollection and re-experiencing context-rich events of the participant’s own life (episodic memories) and were contrasted with the retrieval of semantic memory items including public events of the same time period. Comparison of the network supporting declarative long-term memories irrespective of remoteness revealed significant bilateral activations of the parietal-temporal junction, left temporal pole, anterior cingulate, retrosplenial cortex and cerebellum in the elderly controls. In contrast, AD patients revealed significant activations in left precentral cortex. Autobiographical episodic versus semantic memory retrieval in the controls led to significant bilateral activations of the parietal-temporal junction, left temporal pole, anterior cingulate, retrosplenial cortex and cerebellum. During re-experience of autobiographical event memories AD patients significantly activated middle left temporal cortex, left superior motor cortex and left precuneus cortex. Our data suggests that early AD leads to a loss of specificity in the network supporting long-term memory and to activation of alternative pathways.

COMPARISON OF MEMORY FUNCTION BETWEEN NORMALS AND PATIENTS WITH SCHIZOPHRENIA (PARANOID & NON – PARANOID)

INSTITUTIONS
1. Islamic Azad University of Arsenjan Unit, Iran (Islamic Republic of)

AUTHORS
1. Gholamreza Chalabianloo1, Dr, chalabianloo_f@yahoo.com
2. Marzieh Kavianinia1, chalabianloo_f@yahoo.com

Objectives: Memory is defined as a retrieval procedure of information during time (Durcou & etal, 1999). Memory has a multidimensional structure that each dimension has a specific function in cognitive processing. It has been discovered that memory as one of the most superior cognitive functions, has been affected by the mental disorders. Schizophrenia is the most deteriorative and ominous disorder that cause severe memory dysfunctions (Tamlyn & etal, 1992 ; Nickoli, 1999).

Methods: In order to compare of memory function in patients with paranoid and non-paranoid schizophrenia with normals, 80 patients with schizophrenia were selected from mental hospitals of Shiraz by a random sampling procedure, and matched with 40 normal individuals on the basis of education and age. All participants have completed Wecksler Memory Scale - revised (WMS-R).

Results: Results indicated that there is a significant difference between groups in general memory function (F= 32.62, P <0.01). Also, There are significant differences between groups in the most subscales of WMS-R ,such as verbal memory ( F= 20.71 , P <0.01 ), visual memory ( F= 48.76 , P <0.01 ) , attention and concentration ( F= 11.36 , P <0.01 ) and delayed recall ( F= 30.72 , P <0.01 ). In all subscales, normal participants have shown better performance than patients with schizophrenia.

Conclusion: Our results indicated that psychosis and specially schizophrenia, has sever effects on memory function of patients ,but its sub types such as paranoid or non paranoid, have not significant difference in their memory performance.

P-02-018

ANTIPSYCHOTIC PRESCRIPTION TRENDS IN DEMENTIA CARE HOMES AND THE ROLE OF SPECIALISTS

INSTITUTIONS
1. Edgware Community Hospital, London, United Kingdom

AUTHORS
1. Nikolaos G Christodoulou1, Dr., nikoschristodoulou@gmail.com
2. Patricia Ryan1, Dr.

Background: The prescription of antipsychotics in dementia care homes involves complex decisions based on the knowledge of evidence, clinical risk assessment and holistic judgment. Old age psychiatrists may be best suited to provide this high level of care.

Objective: To compare the prescription of antipsychotics in specialist-supervised and specialist-unsupervised dementia care homes.

Methods: This is a cross-sectional study, in which a chart review was undertaken on all residents (N=102) of three care homes in our hospital’s catchment area.

Results: We found a trend for over-prescription of antipsychotics in specialist-unsupervised care homes (p<0.1), which correlated with significant under-prescription (p<0.001) of benzodiazepines. Cases of antipsychotic polypharmacy were only detected in specialist-unsupervised placements.

Conclusions: In this study, specialist-supervised services appear to adhere better to evidence-based management, compared to specialist-unsupervised services.

ANIMAL ASSISTED THERAPY FOR ELDERLY JAPANESE DEMENTIA PATIENTS: A LONGITUDINAL STUDY

INSTITUTIONS
1. Sapporo City University, School of Nursing, Sapporo, Japan
2. Rakuno Gakuen University, Ebetsu, Japan

AUTHORS
1. Namiko Kawamura¹, RN, MSN, n.kawamura@scu.ac.jp
2. Masayoshi Niiyama², DVM, PhD

Objectives:
This study was a trial evaluation of the long term psychological and behavioral effects of Animal Assisted Therapy (AAT) on elderly dementia patients in a special care unit. It has been theorized that short term AAT will have a positive effect on people suffering from dementia. In an earlier study, these researchers found that institutionalized elderly showed improved emotional well-being following long term AAT sessions.

Methods:
The subjects were eight residents of a private psychiatric hospital in Japan: six females and two males. Volunteers in an occupational therapy program brought two small dogs that residents fed, held and played with over a ten month period. Data was collected three times: pre-therapy, after the sixth therapy session and after the twelfth therapy session. The GBS scale and the Mental Function Impairment Scale (MENFIS) were used in data analysis.

Results:
The GBS scale for intellectual, emotional and other Mental functions showed initial improvement between the pre-therapy and sixth therapy sessions, but then declined by the twelfth session. Motor function continually declined. An item by item comparison showed a significant decrease in ‘Distractibility’ by the sixth session. There was no significant difference with MENFIS. The overall results showed the same pattern: an improvement up to mid-session, but a declined by the last session.

Conclusions:
More study is necessary, but this study suggests that each subject’s needs and goals should be reexamined after an initial period of therapy to maintain the initial positive effect of AAT on mental functions.

10. Kyung-Yeol Bae¹, Dr, MD, psalmpsy@chol.net

Objectives: Prospective findings have not been consistent for folate, vitamin B12 and homocysteine concentrations as predictors of dementia. This study aimed to investigate both baseline concentrations of folate, vitamin B12 and homocysteine and changes in these concentrations as predictors / correlates of incident dementia. Methods: Of 625 elders without dementia at baseline, 518 (83%) were followed over a 2.4 year period and were clinically assessed for incident dementia and Alzheimer’s disease (AD). Serum concentrations of folate, vitamin B12 and homocysteine were measured at both baseline and follow-up assessments. Covariates included age, sex, education, disability, depression, alcohol consumption, physical activity, vascular risk factors, serum creatinine concentration, vitamin intake, and weight change. Results: Only baseline lower folate concentrations predicted incident dementia. The onset of dementia was significantly associated with a relative decline in folate and vitamin B12 concentrations and an increase in homocysteine concentrations over the follow-up period. These associations were reduced following adjustment for weight change over the same period. Conclusions: Incident dementia is more strongly associated with changes in folate, vitamin B12 and homocysteine than with previous concentrations. These changes might be linked with other somatic manifestations of early dementia, such as weight loss.

4. Marek Preiss1, Dr., PhD
5. Hana Stepankova1, Mrs., stepankova@pcp.lf3.cuni.cz

Objectives: The aim of our study was to confirm a hypothesis that speed of searching from semantic memory is slower in patients with dementia than in healthy controls. Methodology: We assessed 17 patients with Alzheimer's or mixed dementia (mean age 74.3±6.1 years, MMSE 15.3±3.3) and a control group of 17 healthy controls (mean age 71.1±5.6 with a short form of a semantic verbal fluency test (name 12 animals as fast as one can) and 2 tests of mental speed (recite the 12 months and count from 100 to 111 as fast as one can). Results: All 17 patients were able to recite the 12 months, 15 patients were able to count, but only 8 patients were able to name 12 animals. Patients took significantly longer to name 12 animals than the controls (Mann-Whitney U test; p<0.001, CI 95% 64.8-122 s vs 12.8-19.3 s). The time to name 12 animals was significantly longer in the dementia group even after controlling for education and mental speed as covariates using MANOVA (F=16.48; p<0.001). Discussion: Non-overlapping confidence intervals between groups suggest that time measurement to name 12 animals could be a quick screening tool for Alzheimer's and mixed dementia.

This study was supported by a grant from IGA Ministry of Health of Czech Republic MZ–I–PCP2005.

Objective: The purpose of this study was to assess the neurocognitive characteristics of the dementia with traumatic brain injury (TBI).

Methods: Subject groups were composed of the dementia with traumatic brain injury patients, 117(26.0%), alzheimer’s disease patients 80(17.8%), psychiatric patients 81(18.0%), brain disease patients without trauma 172(38.2%).

Results and Conclusion: In MMSE, TBI group showed lowest performance than other group with statistical significance. And TBI groups showed lowest performances with statistical significance in the attention, language and related functions, visuospatial functions. In assessment of memory ability, TBI group showed lower ability with statistical significance than other groups, but in Rey Complex Figure Test, TBI group did not showed difference with statistical significance to other group comparing verbal memory. In frontal/executive function assessment, TBI had showed lowest performance than other groups with statistical significance, but did not show statistically significant difference each other in cognitive inhibition like Stroop test, except for psychiatric patients group (lowest performance with statistically significance). In Depression, Barthel ADL and CDR showed lowest performance than other groups, also. Education level had affect on the neurocognitive ability in TBI group with statistical significance, persistently.

**Background:** Recent findings indicate that neurovascular dysfunction contributes to cognitive decline and neurodegeneration in Alzheimer’s disease (AD) (1). Fibronectin (FN), multidomain and multifunctional glycoprotein, is known to exert a strong angiogenic influence on endothelial cells in the CNS (2).

**Objective:** In the present study, alterations in the expressions of the carboxy-terminal (CT-FN), collagen (Collagen-FN), cellular (Cell-FN) and fibrin (Fibrin-FN) domains of plasma fibronectin and the expression of the molecular forms of plasma fibronectin in 30 AD patients, compared with vascular dementia (VD) groups (24 patients) and age-matched control were analyzed.

**Methods:** FN domain concentrations were determined by ELISA using a panel of domain-specific monoclonal antibodies. Western immunoblotting using a monoclonal antibody was performed to analyze the FN molecular forms.

**Results:** In the AD and VD groups, the mean values of the concentrations of CT-FN and Collagen-FN were significantly higher than in the age matched control group. Immunoblotting revealed the presence of 272-kDa and 311-kDa FN bands besides the 237-kDa and 218-kDa bands corresponding to healthy individuals. Densitometry analysis of FN immunoblotting showed that the relative amounts of the 311-kDa and 272-kDa bands in the AD were significantly higher than in the VD and control groups.

**Conclusion:** The plasma FN status can reflect the molecular processes associated with AD state and with aging. The findings seem to be a promising test qualifies as a screening tool for disease risk.

**HOSPITAL UTILIZATION ASSOCIATED WITH ORGANIC SENILE AND PRESENILE PSYCHOSIS (ICD-9, Cod.290). A DESCRIPTIVE LONGITUDINAL STUDY (Spain, 1980-2004)**

**INSTITUTIONS**
1. Agency for Health Technology Assessment, Institute of Health Carlos III. National Health Secretary., Madrid, Spain
2. University of Alcala Faculty of Medicine, Health Sciences and Social Medicine Department, Madrid, Spain

**AUTHORS**
1. Alvaro Medel-Herrero, Mr., alvaro.medel@isciii.es
2. Antonio Sarria-Santamera, Dr., asarria@isciii.es

**AIMS/OBJECTIVES:** To study a series of indicators related with hospital care for organic senile and presenile psychosis (ICD-9, Cod.290) in Spain during a timeframe determined by a process of psychiatric reform and population aging.

**METHODS:** Assessment of national hospital utilization databases: CMBD, EIMH. A descriptive study, 25-year time (1980-2004), divided into five periods of five years. Age and sex adjusted hospital indicators were obtained and analyzed. Hospital morbidity indicators obtained: admission, readmissions, total stays, average stays, time intervals during the hospital stay, timely assisted prevalence and cause for discharge. Gender-disaggregated data. Analysis of time cycles and the age distribution of admission and stays.

**RESULTS:** A decrease of averages stays and increase of admission and total stays for the first two periods of five years (1980-1989) was observed, as well as a decrease in averages stays, admissions and totals stays during the three subsequent periods of five years (1990-2004). In the last five years the average stay is 66 days per admission, the admission rate per 10,000 population is 1.14 and the total stays rate, 75.5. These values represent 10.4% of hospital stays and 4.3% of hospital admissions for all psychiatric disorders (ICD-9, Cod.290-319). 42% of admissions take place in acute hospital areas the remaining 58% in monographic hospitals. Re-admission rate for calendar year is estimated at 4.36%. The average age of the patients increased during the first four periods of five years (1980-1999). In the last five years there has been a decline in average age in both men (75.1 years) and women (78.3 years). Intra-hospital mortality rate per admission is 15.23% (2000-2004).

**CONCLUSION:** Hospital utilization associated with organic senile and presenile psychosis has been high in Spain from 1980-2004, although shows a decreasing tendency in spite of ageing population and an increase in admissions for all psychiatric disorders (ICD-9, Cod.290-319).

Research objective was evaluation of cognitive and uneasy disorders of patients with consequences of cerebral stroke in determination of degree of disablement. Survey of 209 patients of work-capable age with stroke consequences, located in neurology departments of National Center for Rehabilitation of Uzbekistan, Tashkent City Hospital No.1 was conducted. Based on our observations, stroke occurs at 114 (54.5%) men, and 95 (45.5%) women. Patients were classified into 3 periods: 1) early recovery period - 62 (29.7%); 2) late recovery period - 73 (35.4%); 3) residual period - 74 (35.4%) patients. The patients were shared into two group: the main group consisted of 111 patients (53.1%) - patients, who received vinpocetine 10mg 3 time a day during 2 or 3 months, 2 courses a year; and the group of comparison consisted of 98 ones (46.9%).

We were conducting medico-labour examination, which was based on general principles of complex evaluation of medical and social factors. Education, occupation, character of work were considered as social factors. Significant professional displacements were observed in the invalids with mental work, they were losing their occupation. Often over-specialization was required. 18 people of mental work with light cognitive deficit and uneasy disorders were able to work on specialty for a long time, there were 13 (72.2%) people from main group, and only 5 (27.8%) people from comparison group. Rehabilitation potential, in our judgment, also was higher in main group. Therefore, we can draw a conclusion, that vinpocetine influence not only on physical condition, it is also improve social outcome.

THE NEUROPROTECTION OF SOME XENOBIOTIC COMPOUNDS AGAINST THE NEURODEGENERATIVE EFFECTS OF BETA-AMYLOID IN ALZHEIMER’S DISEASE

INSTITUTIONS
1. Neuro Research, Basic NeuroPsychiatry Sciences, London, United Kingdom

AUTHORS
1. Alain Mititelu, Dr, MD, gabrielmittleu@yahoo.co.uk

It is well known that cerebral beta-amyloid pathology is strongly influenced by genetic factors and seems very plausible that a transformation of the diffuse amyloid in cytotoxic (even apoptotic) condensed amyloid could be due to the intervention of non-genetic factors. Amongst exogenous factors, a special influence in this respect seems to be some components of environmental tobacco smoke.

As one in 5 people smoke, the majority of nonsmoking individuals cannot avoid the daily inhalation over years and even decades of chemical xenobiotics from environmental tobacco smoke.

Even contradictory, neurotoxicoepidemiology of Alzheimer’s and other neurodegenerative diseases, support the negative association between smoking and these debilitating diseases.

Based on previous experiments and an strong research activity, the team from NeuroResearch Institute presents a viable hypothesis as a start point for future development of new therapeutic product beginning from MEP.

But what is MEP?

Melanin Exogenous Polymer is a tar quinone-semiquinone radical with natural melanin-like properties (highly reducing scavenger) and anti-apoptotic. Hydroquinone is a competitive apoptotic factor (Ross et al, 1996 Environ.Health Persp.).

Also by reducing the metal cations (Zn and Al) which is known to play an essential role in beta-amyloid aggregation (Smith and Anderton 1994, Neuropathol Applied Neurobiol), MEP interfere successfully in inhibition of polymerization of tau protein into PHF (Mititelu AG, 1998, Alzheimer’s Reports). The new theory expressed here represents the position and personal view of NeuroResearch Institute.

INCIDENCE OF COGNITIVE IMPAIRMENT IN A GROUP OF PATIENTS WITH POSTTRAUMATIC STRESS DISORDER (PTSD), IN COMPARE WITH NEUROTIC PATIENTS

INSTITUTIONS
1. shiraz university of medical science, mentak health service, Iran (Islamic Republic of)

AUTHORS
1. Mojtaba Naghshevarian\textsuperscript{1}, Dr, MD, bahredar_m@yahoo.com

Aims: Iraq invasion during 1980-1987 produced several post traumatic stress disorder (PTSD) suffers among military and Iranian civil. The present study was designed to investigate memory and learning abilities of PTSD patients.

Method: in the present cross sectional study with available simple sampling 20 PTSD patients were compared with 20 patients with anxiety or mixed anxiety depression disorder. They were investigated using semi structural interview for diagnosis of the disorder, impact of event scale and PTSD symptom scale (for PTSD pts only), tow subtest of WMS-R (Verbal & Visual Paired Association and delay Recall), Digit Span (Forward & Backward), Word Fluency, and finally Serial Digit Learning.

Result: Multivariate analysis of variance using reading scores as covariate showed that the PTSD patients had significantly lower score in Verbal Memory (recent & delayed) and Digit Span (Backward). The result also revealed that PTSD patients had generally lower verbal ability in contrast to control.

Conclusion: the data indicates a significant decrement in some cognitive functions after trauma that may relate to structural changes in neurochemical and neurobiological systems in relevant areas of brain. The findings confirm the adverse effect of traumatic event in memory and learning function that may interfere in sleep, family, social and occupational duties.

REASONS FOR HOSPITAL ADMISSIONS IN DEMENTIA PATIENTS DURING 2002-2007

INSTITUTIONS
1. University of Birmingham, Medicine, United Kingdom
2. Queen Elizabeth Psychiatric Hospital, Department of Old Age Psychiatry, United Kingdom

AUTHORS
1. Ammar Natalwala\textsuperscript{1}, Mr
2. Rahul Potluri\textsuperscript{1}, Mr
3. Hardeep Uppal\textsuperscript{2}, Dr
4. Reinhard Heun\textsuperscript{2}, Professor

BACKGROUND: There is a lack of evidence to explain why patients with dementia are admitted to a general hospital.

METHODS: The main reasons for hospitalisation were investigated in patients admitted to a multi-ethnic inner city hospital during 2002-2007, by analysing type of admission and primary diagnosis. Of these, 505 patients were diagnosed with Alzheimer's disease (AD), 283 with vascular dementia (VD) and 1773 with mixed dementia (MD). Logistic regression analysis was used to compare these groups to non-demented controls.

RESULTS: More dementia patients were admitted as emergency cases compared to controls (AD=95.8%; VD=95.4%; MD=96.7%; Controls=54.4%; P<0.001 for all comparisons). The proportion of patients admitted for dementia as their primary diagnosis was small (AD=5.9%, VD=6.0%, MD=6.0%). Primary diagnoses that were significantly more frequent in all three types dementia patients compared to controls were syncope and collapse (P<0.001), urinary tract infection (P<0.001) and dehydration (P<0.001). Acute lower respiratory tract infection, pneumonia and fractured neck of femur diagnoses were more frequent in AD and MD compared to controls (P<0.001 for all comparisons).

CONCLUSION: Dementia patients are often admitted as emergency cases but dementia itself is often not the primary diagnosis. Specific diseases are more common in patients with dementia and further work is required to establish whether this is due to inadequate self or hospital-care, and to impose measures that can reduce the occurrence of these conditions in the dementia population.

We have reported that transgenic (Tg) mice overexpressing human tau protein develop filamentous tau aggregates in the CNS. We overexpressed the smallest human tau isoform (T44) in the mouse CNS to model tauopathies. These tau Tg (PrP T44 Tg) mice acquire age-dependent CNS pathologies including insoluble, hyperphosphorylated tau and argyrophilic intraneuronal inclusions composed of tau-immunoreactive filaments. Therefore, these Tg mice are a model that can be exploited to elucidate mechanisms of tau pathology in various neurodegenerative tauopathies including Alzheimer disease (AD). Aluminum (Al) has been implicated as a potential risk factor for AD in reports from various fields, including epidemiology, cell culture, and animal studies. In the present study, the effects of chronic exposure to Al on PrP T44 Tg mice, which can be considered vulnerable to tau-related pathology, were investigated in order to confirm whether or not Al has any effect on tau lesions. As previously reported animal studies, chronic Al exposure had certain deleterious effects on histology and behavior even on wild type mice, but they were significantly exacerbated in Tg mice. For example, the number of tau-positive inclusions in the spinal cord of Tg mice was decreased, and vacuolar degeneration was prominent, suggesting that cell viability was attenuated and the cells underwent a degenerative cascade rather than containing tau inclusions "safely". These results suggest that chronic Al exposure has a promotive effect on tau-related neurodegeneration.

**Aims/hypothesis:** We set out to investigate the impact of impaired glucose tolerance and duration of diabetes on cognitive performance and to explore coronary heart disease as a potential mediator of this association. Our secondary aim was to explore the effect of birth weight on cognitive performance.

**Methods:** We performed a standard oral glucose tolerance test and a computerised test for cognitive performance (CogState®) on 1147 subjects from the Helsinki Birth Cohort study. At the time for cognitive testing the mean age of the subjects was 64 years and 176 of them had type 2 diabetes. 78 of these had been diagnosed with diabetes before coming to our clinic in the years 2001-2004. Subjects with a history of stroke were excluded.

**Results:** Previously diagnosed diabetic subjects had significantly worse performance in cognitive tasks measuring psychomotor speed, working memory and episodic learning than subjects with normal glucose tolerance. Subjects with newly diagnosed diabetes or milder impairments in glucose tolerance did not differ from the reference group. The association between diabetes and learning was mediated by the presence of coronary heart disease. A low birth weight was associated with slower reaction time in the task measuring attention. Additionally, a low birth weight enhanced the association between diabetes and poor performance in the memory and episodic learning tasks.

**Conclusions:** A longer duration of diabetes is associated with poor cognitive performance. This is only partly mediated by the presence of coronary heart disease. Low birth weight is a vulnerability factor enhancing cognitive decline in diabetics.

Neuro-inflammation, triggered by β-amyloid peptide, is implicated as one of the primary contributors to the pathogenesis of Alzheimer's disease, and several cytokines were identified as key instigating factors. To reveal the inflammatory response of lymphocytes to the neuro-toxic β-amyloid peptide, we evaluated the release of several cytokines from human peripheral blood mononuclear cells using immuno-assays (Elisa). From hyper-acute to chronic effects of β-amyloid peptide were assessed at different concentrations (10⁻⁵ M – 10⁻⁸ M). The pro-inflammatory IL-1β, TNF-α and Rantes, as well as the pleiotropic IL-6 showed a bi-phasic release pattern over time in both low and high doses of amyloid-treatment: after an initial increase, their concentration gradually fell below baseline over time. The release of the suppressors IL-4 and IL-6 was the opposite: an acute depression in their levels was followed by their chronic over-secretion. These results delineate a highly organized pro- and anti-inflammatory response of cells to the neuro-toxic peptide. This is the first study to describe how β-amyloid-induced inflammatory processes in Alzheimer's dementia are regulated.

2. Ramathibodi Hospital, Mahidol University, Psychiatry, Bangkok, Thailand

**AUTHORS**
1. Tatkamon Promma, Miss, MD, mind_tatkamon@yahoo.com

**Objective** To compare the treatment outcome between meditation and group psychotherapy in the treatment of mixed anxiety-depressive disorder.

**Methods** This study was an 8-week randomized controlled trial in 60 mixed anxiety-depressive disorder patients who were suffered from flood disaster at Uttaradit province. Participants were randomly allocated into two groups. Both groups received amitriptyline 25-75 mg per day. Patients in the first group were assigned to the 8-week course of group meditation, one session (1-1.5 hours) per week. Patients in the second group were assigned to the 8-week course of group psychotherapy, one session (1 hour) per week. Participants were assessed by the Hospital Anxiety and Depression Scale (HADS) and the Hamilton Anxiety Rating Scale (HAM-A) at baseline, week 4, and endpoint (wk 8).

**Results** At week 4 and week 8, mean HADS and HAM-A anxiety scores, mean HADS depression score, and the total HADS score of both groups decreased significantly (p<0.05). At week 4, participants who received group meditation improved significantly more than those who received group psychotherapy in both depression and anxiety scores (p<0.05). At endpoint, there was no significant difference in improvement between the two groups. All patients in the meditation group reported benefit from this treatment approach.

**Conclusions** Meditation and group psychotherapy were equally effective in the treatments for mixed anxiety-depressive disorder. Given its convenient and familiarity, meditation is a more favorable approach for the treatment of mixed anxiety-depressive disorder in Thailand.

Step-down inhibitory avoidance (IA) is usually acquired in one single trial, which makes it ideal for studying processes initiated by training, uncontaminated by prior or further trials, rehearsals, or retrievals. Biochemical events in the hippocampus related to long-term memory (LTM) formation have been extensively studied in rats using a one trial step-down IA task. DARPP-32 (dopamine and cAMP regulated phosphoprotein of Mr 32 kDa) is a cytosolic protein that is selectively enriched in medium spiny neurons in the neostriatum. It has been shown that activation of DARPP-32 and the resultant inhibition of PP-1 activity, is of critical importance for the expression of two opposing forms of brain synaptic plasticity, striatal LTD and LTP. Both forms of plasticity are also critically linked to the activation of DA receptors. To our knowledge, no studies have examined the effect of IA task on DARPP-32 expression. In order to demonstrate changes in the protein expression profile we analyzed DARPP-32 levels in the striatum, prefrontal cortex (PFC), hippocampus and entorhinal cortex of Wistar rats after step-down IA learning. Our results showed that IA induced changes on DARPP-32 expression in striatum and hippocampus.

EARLY ONSET AND RAPIDLY PROGRESSIVE DEMENTIA OF UNKNOWN CAUSE: A CASE REPORT

INSTITUTIONS
1. Psychiatry Department of Gazi University Hospital, Turkey

AUTHORS
1. Aslıhan Sayın, aslihansayin@yahoo.com
2. Ulaş Anasoy
3. Selçuk Candansayar

Introduction:
The foregoing is a case report of a female patient, who had an early onset, severe and rapidly progressive dementia, and whose laboratory tests were negative for all possible and well-known etiologic factors for dementia.

Case report:
A 47 year old female patient was referred to our inpatient psychiatry clinic with complaints of forgetfulness and apathy. Her psychiatric history has begun 3 years ago, when she woke up one morning, fell on the floor and screamed for about 2 hours. Afterwards, her forgetfulness has begun, and after a rapid progression (6 months), she became amnestic to almost all past events. Her neurological and mental status examination at her administration included impaired orientation, immediate, short-term and long-term memory, confabulation and agnosia. Her MMT score was 7. Neuropsychological tests battery revealed a general and severe impairment at all of her cognitive abilities. Her laboratory blood tests were within normal limits except low folat (1.9 mg/dl) and zinc (52.17 mg/dl) levels and slightly increased sedimentation (22) rate. Her blood samples were negative for metal poisoning (lead, copper and mercury), tumor and immunological markers. BOS biochemistry was normal except a slightly increased glucose levels (76 mg/dl) and microbiology and culture were negative for all bacterial, viral, prion (JC protein) and fungal infections. There were periventricular and supraventricular milimetric ischemic gliotic white matter areas at her MRI. Her PET scan showed bilateral hipoperfusion of temporal, parietal and frontal lobes. She was given vitamin replacement treatment and was discharged without any symptomatic improvement.

4. Andreas Kruse³, Dr.
5. Johannes Schröder¹, Dr., Johannes.schroeder@med.uni-heidelberg.de

Objective. Autobiographic memory (ABM) comprises memories of one’s own past that are characterized by a sense of subjective time and autonoetic awareness. ABM deficits are among the major complaints of patients with dementia they were not systematically assessed in Alzheimer’s disease (AD).

Method. Using a semi-structured interview, both semantic and episodic aspects of ABM were examined in 211 subjects in different stages of AD (n=164) and mild cognitive impairment (MCI, n=28), respectively, and 19 cognitively non-impaired comparison subjects. Memories from three different life periods were considered; all subjects received a thorough medical and gerontopsychiatric examination.

Results. Findings confirmed a progressive loss of ABM with increasing severity of dementia. While semantic memories remained rather stable until moderate stages of AD, the richness of details in episodic ABM was already compromised in subjects with MCI. A temporal gradient indicating a recency effect was observed in the less affected individuals and predominantly involved episodic ABM’s.

Conclusions. While semantic ABM remains rather preserved up to moderate AD, episodic memories are already compromised with manifestation of the disease. This dissociation supports the view that these memory functions are subserved by distinct neuronal systems. It is suggested that ABM deficits should be addressed/considered in the clinical work-up of patients with AD.

DISCRIMINATION OF FACIAL EXPRESSIONS OF EMOTION BY FRONTOTEMPORAL DEMENTIA PATIENTS: A COMPARATIVE STUDY WITH PROBABLE AD PATIENTS USING SIGNAL DETECTION THEORY

INSTITUTIONS
1. Hospital Magalhães Lemos, Psychogeriatrics, Porto, Portugal
2. University of Coimbra, Institute of Cognitive Psychology, Coimbra, Portugal

AUTHORS
1. Margarida R. Sobral¹, Dra., margarida_sobral@sapo.pt
2. Armando M. Oliveira², Dr., PhD

Frontotemporal dementia (FTD) is a neurodegenerative disease characterized by behavioral disorders that suggest abnormalities of emotional processing. In the past few years several studies investigated the recognition of facial emotion by FTD dementia patients. Evidence gathered converges to suggest that inability to recognize facial emotions in FTD results from inability to recognize emotions rather than from failure in recognizing facial features. The aim of this study was to examine the discrimination of facial expressions of emotions in patients with FTD and to compare it with that of patients with Alzheimer disease (AD). One group of FTD (n = 6), another of probable AD patients (n = 10), and a sample of matched controls (n = 6) were compared on same-different roving tasks involving the discrimination of emotion-conveying faces (of a same person) and of individual faces (same or different persons). Two different sets of stimuli were accordingly used: (1) pairs of intensities of a same emotion, with Fear, Sadness, and Joy as the selected emotions, in the emotion task; (2) pairs of neutral faces in the non-emotion task. Patients and controls were compared on sensitivity and criteria parameters derived from Signal Detection Theory. Patients were moreover assessed with a battery of neuropsychological tests and with the Frontal Behavioral Inventory (Kertesz, 1997). Both groups of patients exhibited a deficit in the discrimination of facial expressions of emotion regarding the controls, with FTD patients showing a more pronounced difference between the emotion and the non-emotion tasks.

PSYCHODRAMA WITH THE ELDERLY IN PSYCHIATRIC HOSPITAL

INSTITUTIONS
1. Hospital Magalhães Lemos, Psychogeriatrics, Porto, Portugal

AUTHORS
1. Margarida R. Sobral, dra., margarida_sobral@sapo.pt

Introduction: Psychodrama can be used with older adults and it may be helpful for improving psychological and behavioural areas (Sobral et al., 2007; Oguzhanoğlu et al., 2005; Carman et al., 1984). The author has conducted a psychodrama group with elderly psychiatric patients without cognitive deficits. This study attempts to investigate the impact of this present psychodrama group on the satisfaction with life and the coping strategies with psychological and behavioural problems.

Method: Three male and five female patients recruited in Psychogeriatrics, Hospital Magalhães Lemos who have attended this present group. None of them had deficits, according to neuropsychological evaluation with Mini Mental state examination (Folstein et al, 1975) and Clock-Drawing Test (Strub et al., 1977). Psychodrama orientated group work sessions were held, during an 18 months period. Each session was 2 hours long and took place once a week. The psychological and behavioural problems were evaluated with Clinical Assessment of Depression Inventory (Vaz Serra, 1994), with Self Anxiety Scale (Zung, 1975), with Symptoms Checklist - SCL-90 (Derogatis, 1973) and with Satisfaction With Life Scale (Diener et al., 1985).

Results: The early warming-up among the members in this group led to dramatization in all sessions. During the study, the psychodrama techniques encouraged spontaneity, creativity, empathy and, consequently, an improvement in communicating with and in helping others and coping with problems. Articulation of emotions and thoughts improved gradually. Total anxiety-depression scores decreased. Satisfaction with life increased.

Conclusion: This psychodrama group has helped older patients because it has improved psychological and behavioural areas.

5. Johannes Schröder, Dr., MD, johannes.schroeder@med.uni-heidelberg.de

Introduction: Elevated levels of total tau protein (t-tau) and of several hyperphosphorylated isoforms (p-tauX) in the cerebrospinal fluid (CSF) of patients with mild cognitive impairment (MCI) and Alzheimer’s disease (AD) are a well established finding. How CSF concentrations of these biomarkers and cerebral morphology relate to each other is only partly understood.

Methods: 23 subjects with MCI, 16 with AD and 15 healthy controls underwent both magnetic resonance imaging and lumbar puncture. Optimized voxel-based morphometry (VBM) was performed to investigate the putative association between CSF levels (t-tau and p-tau181) and gray matter density throughout the entire brain.

Results and discussion: VBM revealed both, elevated t-tau and p-tau181 concentrations to be significantly associated with reduced gray matter density in a variety of cerebral sites comprising temporal, parietal and frontal regions. Within the MCI group, elevated CSF levels of p-tau181 (but not t-tau) were significantly correlated with a pronounced atrophy in the right hippocampus. Elevated CSF levels of t-tau and p-tau181 reflect degenerative processes in AD typical cortical regions. Being related to atrophy in the right medial temporal lobe of MCI patients, our findings support the hypothesis that p-tau181 might be more specifically related to neurodegenerative changes in early AD.

2. Philipp Thomann¹, Dr., MD, philipp.thomann@med.uni-heidelberg.de
3. Vasco Dos Santos¹
4. Marco Essig², Dr., MD
5. Johannes Schroeder¹, Dr., MD, Johannes.schroeder@med.uni-heidelberg.de

**Background:**
The Clock Drawing Test (CDT) is a widely used instrument in the neuropsychological assessment of patients Alzheimer’s disease (AD). As CDT performance necessitates several cognitive functions (e.g. visuospatial and constructional abilities, executive functioning), an interaction of multiple brain regions is likely.

**Methods:**
51 subjects with mild cognitive impairment, 23 with AD and 15 healthy controls were investigated using magnetic resonance imaging. Optimized voxel-based morphometry (VBM) was performed to investigate the putative association between CDT performance and gray matter (GM) density throughout the entire brain.

**Results:**
In the first step of analysis (p<0.001, uncorrected), VBM revealed a reduced GM density in numerous cortical (temporal lobe, frontal lobe, cerebellum) and subcortical (thalamus, basal ganglia) brain regions to be associated with poorer CDT performance. When corrected for multiple comparisons over the whole brain (p<0.01), the associations remained significant in the left temporal and - less pronounced - the right temporal lobe.

**Conclusion:**
VBM demonstrated an impaired CDT performance to be significantly correlated with atrophic processes in multiple brain regions, reflecting the fact that CDT performance requires an interaction of several cognitive domains. The observed structural alterations were pronounced in the temporal lobe, a region which is known to be affected early in the course of AD.

Yokukansan (YKS, Yi-gan san in Chinese), which is a traditional Japanese medicine, has been approved by the Ministry of Health, Labor, and Welfare of Japan as a remedy for neursis, insomnia, and irritability. Recently, YKS has been reported to improve behavior and psychological symptoms of dementia (BPSD). However, the mechanism of these effects remains unclear. Abnormalities of the serotonin system have showed a significant correlation with BPSD, including overactivity and psychosis in Alzheimer’s disease patients. In the present study, we investigated the effect of YKS on head-twitch response induced by 2,5-dimethoxy-4-idoamphetamine (DOI, 5 mg/kg, i.p.), a 5-HT₂A receptor agonist, in mice that represents hallucinations. We found that acute treatment with YKS (100 and 300 mg/kg, p.o.) had no effect on the DOI-induced head-twitch response, whilst 14 days repeated treatment with YKS (300 mg/kg, p.o.) significantly inhibited this response. Moreover, we measured the expression of 5-HT₂A receptor protein by Western blotting. Repeated treatment with YKS (300 mg/kg, p.o.) decreased expression of 5-HT₂A receptors in the prefrontal cortex but not in the hypothalamus. Thus, YKS inhibited the DOI-induced head-twitch response by down-regulation of the cortical 5-HT₂A receptors, which suggests the involvement of the serotonin system in psychopharmacological effects of YKS.

**Objectives:** The aim of study is to demonstrate efficacy of rivastigmine and memantine in the treatment behavior and psychological symptoms of Alzheimer's dementia, compared to atypical antipsychotic risperidone. AD disease is a progressive neurodegenerative disorder with impairment of cognition, behavior, activities in daily living and quality of life.

**Methods:** In this 12 weeks comparative study 25 inpatients and outpatients with AD disease aged 60-85 years were randomly assigned to receive either monotherapy with rivastigmine, memantine, risperidone or combination memantine/risperidone and rivastigmine/risperidone, at medium doses, in order to compare their effect on behavioral and psychological symptoms such as agitation, hallucinations, aggression, depression and wandering, as well as cognitive performance. The main instruments used were BPRS, CGI, MMSE and structured interview according to ICD-10. Evaluation was made at baseline and after three months.

**Results:** All patients completed study, at baseline they had mild to moderate cognitive decline with psychological symptoms. At the end point of trial rivastigmine and memantine significantly reduced agitation, depression and delusions, improved sleep disturbances and moderate cognitive improvement. Risperidone group showed similar result related to psychotic symptoms. The best results on psychological symptoms demonstrated combined therapy.

**Conclusion:** Rivastigmine and memantine showed in our study similar effects on psychological symptoms of AD as atypical antipsychotic.

**AUTHORS**  
1. Huali Wang, Dr., MD, PhD, huali_wang@bjmu.edu.cn  
2. Xin Yu, Prof., MD  
3. Tao Li, Dr., MD

**Objective:** To investigate the neuropsychiatric features of Alzheimer’s disease (AD) and mild cognitive impairment (MCI) in memory clinic setting.

**Methods:** Fifty-seven AD patients, 28 MCI subjects and 46 normal elderly controls were recruited in the memory clinic at Peking University Institute of Mental Health. Neuropsychiatric features were assessed with Neuropsychiatric Inventory (NPI), and general cognitive status was evaluated with MMSE.

**Results:** After controlling the effect of age and education, the total score of NPI was significantly different only between AD and control group (P<0.05). There was no significant relationship between total scores of NPI and MMSE (P>0.05). In AD group, the total score of caregiving distress was significantly associated with that of NPI (r=0.92, P<0.05).

**Conclusion:** It is suggested that in memory clinic, the problem associated with hallucination, agitation, apathy, irritability, and abnormal motor behaviors were more pronounced in AD than MCI individuals. Thus, the study indicates that neuropsychiatric symptoms should be attended to more closely in memory clinic services.

2. Jae-Min Kim 1, MD, PhD
3. Jin-Sang Yoon 1-2, MD, PhD

Aims: The purpose of this study was to investigate the effect, safety, and tolerability of risperdal oral solution (risperdal sachet) with lorazepam tablet versus intramuscular haloperidol and lorazepam injection for management of acute psychotic symptom in the elderly with organic mental disorder.

Methods: Total 37 patients who have dementia, medical or physical diseases, associated with acute psychotic symptoms were randomly assigned to oral treatment with 1mg of risperdal sachet (oral solution) plus 1mg of lorazepam tablet (N=17) or to intramuscular treatment with 2.5mg of haloperidol injection plus 2mg of lorazepam injection (N=20). The change of CGI scores was used for evaluation of efficacy.

Results: The mean of CGI scores at 15, 30, 60, and 120 minutes after dosing was changed significantly and psychotic symptoms were improved significantly at each time point in both groups (p<0.001). There was no group difference of improvement (p=0.189).

Conclusion: A single oral dose of risperdal sachet (oral solution) plus lorazepam was as effective and tolerable as parenterally administered haloperidol plus lorazepam for the rapid control of acute psychotic symptom in the elderly with organic mental disorder.

PURPOSE: galantamine is a reversible, competitive cholinesterase inhibitor that also allosterically modulates nicotine acetylcholine receptors. Inhibition of acetylcholinesterase, the enzyme responsible for hydrolysis of acetylcholine at the cholinergic cognitive impairment. To evaluate the efficacy, safety and tolerability of galantamine in long-term in Mild Cognitive Disorder.

METHODS: a multicenter, open label, prospective, observational study enrolled 800 patients, more 50 years old with Mild Neurocognitive Disorder (DSM IV criteria), during 24 months of treatment with galantamine 16 mg./day. Assessments included the Mini Mental State Examination (MMSE), Clinical Dementia Rating (CDR), Alzheimer’s Disease Assessment Scale (ADAS-COG), Seven minutes test, Wisconsin card sorting test, Token test, Raven Test, Trail making test, Functional Activities Questionnaire (FAQ), Deterioration Scale, Global Clinical Impression (GCI) and UKU scale of Adverse Effects.

RESULTS: a total 800 outpatients were treated with 16 mg./day galantamine during 24 months, the therapeutic response evaluated with CDR, MMSE and the tests and scales of function cognitive measuring, GCI and UKU scale of adverse effects, comparing the baseline to final scores.

CONCLUSION: Mild Cognitive Disorder is being examined, so there aren’t enough treatment for this. A long-term treatment (24 months) galantamine improves cognition and global function, behavioural symptoms and the general state well being of patients with Mild cognitive Disorder. With incidence of adverse effects not significant and a very good profile of safety, the final results of the study suggest that galantamine may be particularly appropriate in the Mild Cognitive Disorder.

To evaluate the efficacy of galantamine-escitalopram association in patients with Mild Cognitive Disorder and Depression. So there is a possible relation between the deficit of cerebral oxygenation and depression or relation between the serotonin system and cholinergic system in relation with disease comorbidity cognitive-depression

OBJECTIVE: To evaluate the therapeutic response in patients with comorbidity between Mild Cognitive Disorder and Depression in treatment with Galantamine, Escitalopram and the two drugs associated.

METHOD: A group of 300 patients with symptoms of Mild Cognitive Disorder and Depression (DSM IV-R criteria) were separated in 3 groups of 100 patients. Each group received different treatment in an 8 months period:
Group 1: Galantamine 16 mg/day.
Group 2: Escitalopram 20 mg/day.
Group 3: both drugs, same dose.

RESULTS: The therapeutic response evaluated in Hamilton Scale for Depression (HAM-D), Montgomery and Asberg Depression Rating Scale (M.A.D.R.S.), Mini Mental State Examination (M.M.S.E.) and Global Clinical Impression (G.C.I.) scores during 8 months. In the third group who received the two drugs associated, had much better response than the others and “brain enhancer”.

CONCLUSION: The group who received the association of the nootropic agent Galantamine with antidepressant (SSRIs) Escitalopram had a relevant satisfactory therapeutic response (the best result), so there is a possible relation between the deficit in cholinergic systems and depression. Could be cerebral cholinergic systems deficit a generator of Depressive Disorder?

Aim: For assessing the personality characteristics of a sample of Iranian psychiatrists and their ways of coping against stressful events.

Method: 87 Iranian psychiatrists completed the Temperament and Character Inventory (TCI) and Ways of Coping (WAYS) questionnaires.

Result: Psychiatrists personality had no significant difference, in each of the temperament and character domains, by norms of general population. Investigating the correlation between different methods of coping with stressful events, and different kinds of personality, the results showed that higher level of novelty seeking was associated with more problem focused coping, more wishful thinking and more seeking social supports. On the other hand, higher level of harm avoidance was associated with less detachment, less seeking social support, and more self isolation, while higher level of persistence was accompanied by more problem focused coping, and more wishful thinking.

Conclusion: This study shows that psychiatrists with different personality temperaments and characters had different methods of coping in stressful conditions. Moreover our results failed to show any difference between psychiatrists' personality and normal population.

A REVIEW OF 60 BORDER LINE PERSONALITY DISORDERS RECORDED IN 2007 IN KOLKATA

INSTITUTIONS
1. Calcutta Pavlov Hospital, Psychiatry, Kolkata, India

AUTHORS
1. Asis Kr. Acharya1, Dr., DIH(cal), DPM(Cal), drasisacharya@yahoo.com

Objectives: Border line personality Disorders (BPD) are frequently found in busy urban clinics. On longitudinal observation they are usually diagnosed after several visits and also their dramatic presentation, blaming to others and liability of their moods, and their peculiar aloofness and a sense of boredom or emptiness. Their presentation as well as patterns differ in different cultures & countries.

Methods: 60 new cases those were finally diagnosed after careful clinical evaluation in Calcutta Pavlov Hospital in the year 2007 were studied here. Diagnosis were based on DSM-IV-TR diag. criteria.

Results: 34 male & 26 females, age ranging from 24 to 46 yrs with a median average of 31 yrs. were assessed here. Among nine contexts described in DSM-IV-TR the symptoms most found here are: 1) Unstable interpersonal relationship 2) Identity disturbance as inner "self" is not at ease with the outer "expressed self" 3) Impulsivity 4) Aggression to self & others 5) Frantic efforts to avoid imagined abandonment, 6) Marked affective instability. Self mutilating (wrist slashing etc.) were more marked in females. Spending, joblessness and poverty are noted more in males with suicidal attempts & sexual promiscuity. BPD patients were mostly brought by their spouses (64%), and by parents or in-law parents. Friends were conspicuously absent in the scenario. Marriage is stake in BPD cases. A 25% divorce, 23% desertion living alone were noted.

Conclusions: In BPD cases there are deterioration in social, occupational, & financial sate & quality of life. Clinician should borne in mind of this differential diagnosis.

Background: We aimed to develop a tool to measure sexual aggression and passivity and investigate the relation with sexual orientation.

Methods: A cross-sectional survey was carried out in a sample extracted from the population of University of Athens, Greece. We used a questionnaire of 70 items, regarding the sex, age, university attribute, sexual orientation, frequency of acts of sexual aggression and passivity, sexual competence and desire of the participants.

Results: In total 994 subjects answered the questionnaire. The calculated sexual aggression and passivity scores range from 0 to 101 and from 0 to 97 respectively. The upper cut-off of sexual aggression and passivity for male heterosexuals is 25.5 and 19.33 respectively, for homosexual males 75 and 59, for heterosexual females 15 and 23.33 and for homosexual women 26 and 36 respectively. The differences of the mean score of aggression between the above sub-groups are statistically significant. The differences of the mean score of passivity between homosexuals and heterosexuals of the same sex are statistically significant. The mean rate of rejection of sexual practices of aggression and passivity is affected by sexual orientation. Sex and sexual orientation were identified as independent variables affecting significantly sexual aggression. Sexual passivity is affected significantly by sexual orientation and age. Sexual competence (erection and sexual desire) was identified as independent variable affecting sexual passivity.

Conclusion: Our study provides evidence that sexual orientation is strongly associated with sexual aggression and passivity.

4. Sonia González Bardanca4, Dr., MD
5. Yolanda Prieto-Paredes5, Dr., MD
6. María J Ávila-González1, Dr., MD

Objectives: to evaluate the incidence of stroke among psychiatric patients and cardiovascular risk factors.

Material and Methods: We analyzed all patients diagnosed from stroke admitted to a community hospital between 1-1-2007 and 1-1-2008. Variables like age, sex, stroke location, psychiatric diagnosis and cardiovascular risk factors were reported.

Results: A total of 104 strokes were included. In 62 (59.61%), psychiatric comorbidity was found: 43 were women and 19 men. Mean age 72 (59-84) years. The most frequent psychiatric diagnosis was alcohol abuse (35, 56.45%) followed by anxiety (22, 35.48%) and depression (17, 27.41%). In the control group (42 patients), 27 were women and 15 men. Mean age 75 (61-92) years. When comparing risk factors for stroke in both groups, psychiatric patients smoke more frequently (p=0.021), were more sedentary (p=0.016) and have greater levels of total cholesterol (p=0.011) and lower HDL-cholesterol (p=0.039). No differences were found in the incidence of diabetes mellitus, levels of LDL cholesterol and triglycerides. The most common stroke location was the left middle cerebral artery followed by the right middle cerebral artery in both groups.

Conclusions:
1.- A majority of patients suffering from stroke have some degree of psychiatric comorbidity in our study (59.61%) been alcohol abuse the most frequent psychiatric diagnosis.
2.- Smoking and sedentary are more frequent in psychiatric patients reflecting a less healthy lifestyle in these patients.
3.- Total cholesterol was higher and HDL-cholesterol lower. This feature is consonant with the higher prevalence of the metabolic syndrome in psychiatric patients as compared with the general population.

6. MR Mohammadi1  
7. H Kaviani1  
8. Z Bayat1  
9. A Sadeghi1  
10. H Parsafar1

Aim: This study investigated psychological profile and burnout among a sample of Iranian psychiatrists.

Method: General health questionnaire (GHQ-28) and temperament and character inventory (TCI) for assessing psychological profile and the Maslach Burnout Inventory (MBI) as a measure of burnout were used. In addition, demographic data such as age, sex, marital status were also inquired. Subjects selected randomly among psychiatrists who participated in annual national Iranian psychiatric association congress

Results: In this study 87 psychiatrists participated. 12.6% of psychiatrists showed mental disorder which is less than general population in Iran. Their personality profile didn't show any significant differences, in any of the temperament and character subscales, in compared with general population's norms. Average scores level of burnout was reported in low range on personal accomplishment and emotional exhaustion subscales, and was in average range on depersonalization subscale. There is not any significant correlation between sex, and temperament and character characteristics of personality with the level of burnout. Age and GHQ like rt score showed a significant positive relationship with the level of burnout. (p<0.05)

Conclusion: Psychological symptoms can affect burnout among psychiatrists. Problems of general health, as well as mental health and burnout, among psychiatrists are in need of attention.

Introduction: Neurosyphilis is a potentially fatal infectious disease that has a long history of association with psychiatry. Recent studies reported that 15-20% of the cases presented psychiatric manifestations after 15-20 years of the primoinfection. The complexity of its clinical picture requires a multidisciplinary approach. Today due to drug treatment, penicillin, usually is a rare complication and the first symptoms may be psychiatric.

Objectives: Description of a case of neurosyphilis that began with psychiatric symptoms.

Methodology: We present a case report, a review of the literature and a discussion

Results: Case report: This is a 54 year old male who presented a clinical case consisting of tremors widespread, disruption of the march, urinary incontinence, loss of strength and spoke inconsistent with laughter unreasonable. He had entered the Psychiatric servi-

ce 3 months earlier by a depression with psychotic symptoms that responded to treatment with imipramine 150 mg / day and risperidone 2 mg / dia. Serology was positive for TPHA and VDRL and CSF was positive VDRL. The diagnosis was neurosyphilis and we started a treatment with penicillin and steroids and the patient improved in a few days.

Conclusions: This clinical case shows the complexity of this disease emphasizing the importance to maintain a high level of diagnostic and justifying the screening of neurosyphilis in psychotic symptoms.

Stigma and cultural barriers may discourage alcohol and drug treatment-seeking. Arab Americans are reported to stigmatize substance use and may experience cultural barriers to obtaining treatment. To explore pathways to treatment, we administered questionnaires and interviewed ten Arab Americans who were or had been in substance abuse treatment. The diverse sample included five with co-occurring mental disorders, eight men and two women, nine Muslims and one Christian, seven treated for alcoholism and three for drug use, and different countries of origin, generation and language proficiency. The participants reported high Arab community stigmatization of alcohol and marijuana use. Participants in recovery perceived the Arab community as more supportive of treatment seeking than those still using alcohol or drugs. Families and friends, once convinced of the need for treatment, were supportive but lacked the knowledge to recognize substance abuse. Surprisingly, half the participants had a family history of substance abuse which did motivate the participants to seek and stay in treatment. Religion was ranked as extremely important to almost all the participants. Only six participants reported their religion discouraged alcohol use. Criminal justice involvement and mental health referrals were major pathways to treatment. Cultural barriers to accessing and staying in treatment were common; counselor ethnic-matching did not eliminate this barrier. In conclusion, stigma in the Arab community may discourage substance use but it may also contribute to delays in treatment seeking. Cultural competency of programs and counselors appeared to influence both access to treatment and retention.

PREVALENCE AND CLINICAL CONSEQUENCES OF DUAL DIAGNOSIS

INSTITUTIONS
1. Institut Pere Mata, CPU, Reus, Spain

AUTHORS
1. Sara Arranz1, Sarranzgarcia@hotmail.com
2. Olga Gonzalez1
3. Samuel Pombo1
4. Beatriz Pascual1
5. Ines Niubò1
6. Joan Peña1

Introduction: The co-occurrence of a severe mental illness and a substance abuse or dependence disorder is common. Substance use disorders can occur at any phase of mental illness. Causes of this comorbidity may include self-medication, genetic vulnerability, environment or lifestyle. The consequences of dual diagnosis include poor medication compliance, physical comorbidities, poor health, increased risk of suicide.

Objective: The aim of the present study was to determine the prevalence of dual diagnosis and its clinical consequence in a psychiatric institution in Reus (Spain).

Method: The sample consisted of 120 short-stay inpatients, which were hospitalised in our admission Unit. We obtain clinical and demographic variables from the clinical history. The software used in analyses was SPSS v.12.00.

Results: Of the 120 patients, 65 (54.2%) were male, and 55 (45.8%) were female. The mean age was 45 (SD= 14.9). Thirty-two (26.7%) patients have dual diagnosis. The psychiatric diagnostic more prevalent was the psychotic disorders (67.5%) and the substance abuse more prevalent was the alcohol (21.3%). We found differences between patients with dual diagnosis and those without, respect to adherence to treatment, negative PANSS in psychotic patients and age of onset (a < 0.001)

Conclusion: Nearly one third of the inpatients were shown to suffer dual diagnosis. These patients with dual diagnosis have an earlier onset of the psychiatric illness and a worst adherence to treatment. However, the identification of reliable dual diagnosis is important, because its patients may have a poor outcome.

RELATIONSHIP BETWEEN FIBROMYALGIA AND SOMATIC SYMPTOMS OF DEPRESSION: DIAGNOSTIC AND THERAPEUTIC IMPORTANCE

INSTITUTIONS
1. S. M. S. MEDICAL COLLEGE, PSYCHIATRY, JAIPUR, India

AUTHORS
1. Lalit Batra¹, Dr., md_lalitbatra@hotmail.com

Objectives: Physical symptoms are common in depressed patients and are major obstacle in the effective management of depression. In the clinics, a high number of patients present (69%) with somatic symptoms overlapping with fibromyalgia. Hence, present paper will focus on the interrelationship of fibromyalgia and somatic symptoms of depression.

Method: We searched the literature with the keywords “fibromyalgia”, “somatic symptoms of depression”. Results were retrieved and reviewed.

Results: Fibromyalgia is a disorder of central sensitization and also that depression is associated with central sensitization to induce headache at least. It may be one reason why depressed subjects complain of generalized pain. Based on the available literature we hypothesize that fibromyalgia, headache and depression may be different presentations of a similar illness and may lie at the different points of a spectrum. As fibromyalgia and headache are not seen in all depressed patients, there could be two possibilities: few of the depressed subjects are predisposed to develop these symptoms during depression; or the central sensitization occurs after the depression reaches a critical level in terms of severity, duration etc. and when it is reached, depressed patients develop headache and/or fibromyalgia. Strong evidence has accumulated to support the hypothesis that a deficiency in serotonergic neuronal functioning might be related to the pathophysiology of fibromyalgia. Patients with fibromyalgia were found to have decreased concentrations of 5-HT and tryptophan in serum and CSF similar to depression.

Conclusion: We conclude that fibromyalgia and “somatic symptoms of depression” are closely related.

THEORETICAL, CLINICO-PSYCHOPATHOLOGICAL AND CROSSCULTURAL ASPECTS OF CRIMINAL AGGRESSION IN FORENSIC-PsYCHIATRIC PRACTICE

INSTITUTIONS
1. The Serbsky National Research Centre for Social and Forensic Psychiatry, Division functions as scientific-methodical centre on forensic psychiatry, Moscow, Russian Federation

AUTHORS
1. Natalya Batueva¹, Mrs, MD, berinted@yandex.ru

Aims: The paper presents analysis of impact of social-psychological factors on behavior control in terms of shaping criminal aggression. The theoretical aspects of the impact of social-psychological (including ethnocultural) factors on behavior control in terms of shaping criminal aggression as well as their biological basis are defined. Two major mechanisms of regulation of legal behavior are identified and their adaptive nature is established.

Results: 191 subjects with psychic disorders, who had committed aggressive unlawful actions in Bjujratia Republic, underwent forensic-psychiatric investigation. 97 subjects without psychic disorders had committed analogous unlawful acts. The character of psychopathologic disorders and the correlations with socio-psychological factors is described. Two main mechanisms of socio-psychological personal regulation through cognitive and affective-willed sphere of psychic action are shown. Their different predominance in two ethnical subpopulations (Slavonic and Bjujratic) is shown too. Their correlation with peculiarities of psychopathologic disorder which influence social adaptation of persons with psychic disorders is ascertained.

Conclusion: It is assumed that social decompensation occurs primarily as a result of weakening or disruption due to psychic derangement of an intellectual or volitional component of psychological regulation which is least protected by the primary mechanism of regulation.

GNOSEOLOGICAL DIFFERENCES BETWEEN DELIRIUM AND PHENOMENA OF SOCIAL CONSCIOUSNESS

INSTITUTIONS
1. Naberezhnye Chebry Out-Patient Department, Naberezhnye Chebry, Russian Federation

AUTHORS
1. Isaak M. Bekker1, Dr., MD, nchpnd@mail.ru

Trying to find the definitions of some psychiatric phenomena from the viewpoint of philosophic gnoseology, we have studied a number of articles published in independent psych. Journ. in the period of 2001-2006. The subject of our article is to discuss the differences between delirium and phenomena of social consciousness (in particular, belief in extra-sensory perception).

A believer accepts some knowledge as ‘doxa’, i.e. takes it on trust. Such a person says, “I just believe and I do not need the proof of existing God, telepathy, extra-sensory perception”. Thus the phenomenon of believing in ESP remains in the sphere that is immanent in consciousness, it does not transcend consciousness. From the viewpoint of phenomenology, it remains problematic. From a gnoseological standpoint, delirium is “episteme”, i.e. the truth that is accepted as apodeictically determined one. From the viewpoint of philosophy, the phenomenon of delirium that is immanent in a patient's consciousness is transferred into a transcendent sphere and becomes objective. In other words, being immanent in consciousness the phenomenon of delirium is intentionally aimed at transcendently existing events, facts or objects. Therefore it changes the ontological status of existing a patient who begins to live in a different world where problematically existing phenomena are taken by morbid consciousness for apodeictically existing ones. If a delirious judgment, i.e. an experience, is considered “cogitatio” and the content of this judgment is “cogitatum” then the essence of morbid consciousness is expansion of apodeictic existence of a patient’s experiences to his or her judgments.

COMBINED THERAPY WITH INTERPERSONAL PSYCHOTHERAPY OF BORDERLINE PERSONALITY DISORDER: A COMPARISON WITH MEDICATION THERAPY

INSTITUTIONS
1. University of Turin, Unit of Psychiatry, Department of Neurosciences, Torino, Italy

AUTHORS
1. Silvio Bellino1, Dr., MD, silvio.bellino@unito.it
2. Monica Zizza1, Dr., PhD, silvio.bellino@unito.it
3. Marina Fenocchio1, Dr., MD, silvio.bellino@unito.it
4. Fabio Fermo1, Dr., MD, silvio.bellino@unito.it
5. Filippo Bogetto1, Dr., MD, silvio.bellino@unito.it

Objective: Combined treatment with interpersonal psychotherapy and antidepressants has been found more effective than pharmacotherapy alone in depressed patients with concomitant borderline personality disorder (BPD). The aim of this study is to investigate whether combined treatment with a modified version of interpersonal psychotherapy is still superior to antidepressants when treating patients with a single diagnosis of BPD.

Methods: Forty outpatients with a DSM-IV-TR diagnosis of BPD were enrolled. They were randomly assigned to two treatment arms for 32 weeks: (1) fluoxetine 20–40 mg/day plus clinical management; (2) fluoxetine 20–40 mg/day plus IPT adapted for BPD (IPT-BPD). Seven patients dropped-out for noncompliance. Patients who completed the treatment period were assessed at baseline, and at week 8, 16 and 32 with: CGI-S; HDRS; HARS; SOFAS; BPD Severity Index, and a questionnaire for quality of life (SAT-P). Univariate GLM was performed with two factors: duration and type of treatment.

Results: Remission rates, CGI-S, HDRS, SOFAS, and total BPDSI score changes were not different between treatments. Combined therapy had better effects on the HARS, the items “interpersonal relationships”, “affective instability”, and “impulsivity” of BPDSI, and the factors “psychological functioning” and “social functioning” of SAT-P.

Conclusions: Combined therapy with adapted IPT is more effective than fluoxetine alone in BPD patients, if considering a few core symptoms of the disorder, anxiety and quality of life.

6. Béchir Ben Hadji Ali1, Pr., MD, bechir_benhadjali@yahoo.fr

Personality disorders (PD) are common in patients with major depression disorder (MDD) and often responsible of impaired outcome.

Objective
To determine the impact of PD on MDD outcome, this study aimed to compare two groups of depressive patients with and without PD.

Methods
Its a comparative study held in the psychiatric female inpatient unit of Farhat hached university hospital of Sousse (Tunisia). All first time admissions, between January 1999 and December 2006, for MDD according to DSM-IV criteria, were retrospectively examined (N=277), and split into two groups:
Group 1 (G1): inpatients with MDD and comorbid PD (n=159).
Group 2 (G2): inpatients with MDD, without comorbid PD (n=118).

Statistical comparisons were performed between the two groups and based on demographic, clinical and outcome features available in patients medical charts.

Results
Inpatients from G1 had earlier age of onset of their depressive disorder (p<10^-3) and reported more previous suicidal attempts (p=0.002) and more axis I comorbid disorders (p<10^-3). After remission of index episode, they had more persistent depressive symptoms (p=0.035), more relapses (p=0.025) and suicidal attempts (p=0.001).

Conclusion
More than half of our depressive inpatients had comorbid personality disorder. This comorbidity was correlated to persistent depressive symptoms, relapses and suicidal attempts.

RELATIONS BETWEEN ALEXITHYMI A, PSYCHOLOGICAL VULNERABILITY, AND PSYCHOLOGICAL WELL-BEING

INSTITUTIONS
1. University of Tehran, Department of Psychology, Tehran, Iran (Islamic Republic of)

AUTHORS
1. Mohammad Ali Besharat1, Dr., PhD, besharat@ut.ac.ir

Objectives: To investigate the relations between alexithymia, psychological vulnerability, and psychological well-being in a sample of students.

Methods: A correlational analysis was performed to assess the kind of association exist among alexithymia and its three components including difficulty identifying feelings, difficulty describing feelings, and externally oriented thinking with psychological well-being, psychological distress, anxiety, and depression. Three hundred and six students (136 boys, 170 girls) from the University of Tehran were included in this study. All participants were asked to complete Farsi version of the Toronto Alexithymia Scale (FTAS-20), Mental Health Inventory (MHI), Beck Anxiety Inventory (BAI), and Beck Depression Inventory (BDI).

Results: Alexithymia showed a significant negative association with psychological well-being as well as a significant positive association with psychological distress, anxiety, and depression. The results also revealed that total alexithymia and difficulty identifying feelings can predict changes of psychological vulnerability and psychological well-being. Externally oriented thinking could predict only changes of anxiety.

Conclusion: It can be concluded that alexithymia is associated with mental health, anxiety, and depression indices. Results and implications are discussed.

Keywords: alexithymia, psychological vulnerability, psychological well-being

EFFECT OF DEPRESSION ON SLEEP: QUALITATIVE OR QUANTITATIVE?

INSTITUTIONS
1. University College of Medical Sciences and GTB Hospital, Psychiatry, Delhi, India

AUTHORS
1. Manjeet S Bhatia¹, Dr, MD, manbhata1@rediffmail.com
2. Sushant Dahiy⁰, Dr, MBBS
3. Ravi Gupta¹, Dr, MD, guptaravi_2003@yahoo.co.in

Background: Present study was designed to assess whether subjective sleep pattern differ between (i) depressed patients and controls and (ii) between subjects with different severity of depression. Based on available literature it was hypothesized that sleep pattern must be different between above mentioned groups.

Method: This study included sixty subjects with major depressive disorder and forty subjects in the control group. Subjects with sleep disturbance secondary to any other factor e.g., medical illness, environmental factors, other psychiatric illness etc. were not included in the study. Depression severity in subjects with depression was assessed with the help of Beck Depression Inventory II. Subjective sleep complaints were asked in the presence of a reliable informant, preferably bed partner. All the information was recorded in a semi-structured performa.

Results: Depression and control groups were similar with regards to age (p=0.32) and gender (p=0.14) distribution. Subjects in depression group had lesser total sleep time (p=0.001), longer sleep latency (p=0.001), frequency awakenings (p=0.04), greater wake after sleep onset and offset times (both p=0.001), lesser sleep efficiency and tend to wake up early (Mann Whitney U=913.5; p= 0.05). Subjects with severe depression were different from the mild and moderate group on total sleep time (p=0.002), nighttime sleep (p=0.007) and sleep efficiency (p=0.001) even when three groups were comparable in age.

Conclusion: Depression is associated with sleep disturbances not only qualitatively but also quantitatively. The sleep disturbance arises only after a critical level of depression is reached and depression of varying severity may selectively affect sleep parameters.

DIFFERENCES IN THE COURSE OF DEPRESSIVE SYMPTOMATOLOGY IN PATIENTS WITH OR WITHOUT MIGRAINE-COMORBIDITY DURING ANTIDEPRESSANT TREATMENT WITH FLUVOXAMINE AND VENLAFAXINE

INSTITUTIONS
1. Istituto Scientifico Ospedale San Raffaele - Turro, Department of Neuropsychiatric Sciences, Milan, Italy

AUTHORS
1. Fanny Bongiorno¹, MD, bongiorno.fanny@hsr.it
2. Danilo Dotoli¹, dotoli.danilo@hsr.it
3. Enrico Smeraldi¹, MD, smeraldi.enrico@hsr.it

Introduction Migraine is the headache subtype that has been most extensively investigated for psychiatric comorbidity. In a previous study on euthymic patients in long-term treatment with lithium or SSRIs, we supported the hypothesis of a bidirectional association between these two diseases. There are no evidence-based indications to date about treatment of migraine associated with mood disorders.

Methods We compared the course of depression during four weeks treatment with fluvoxamine or venlafaxine at high dose in a sample of 238 inpatients affected by major depression, subdivided according to the presence of migraine associated with mood disorders.

Results At the end of the observation period, the antidepressant response rate in the whole sample was 66.5%. Regression Analysis identified younger current age, choice of antidepressant drug, total number of depressive episodes and duration of current episode as the clinical variables significantly related to the antidepressant response. In the migraine depressed sample there is a statistical difference in the decrease of HAM-D scores during the treatment with fluvoxamine and venlafaxine.

Discussion Our data indicate that migraine comorbidity does not affect antidepressant response di per se in primary mood disorder patients. Nevertheless, in migraine sample the administration of SNRI determined a faster improvement of depressive symptomatology when compared with SSRIs. These results confirm that venlafaxine is efficacious in the treatment of migraine depressed patients.

CAN DRAGONS BE TURNED TO DAFFODILS? BORDERLINE POLICIES TO BORDERLINE PATIENTS: IS THERE A (MIDDLE) WAY?

INSTITUTIONS
1. Amazonic Alpha, Psychiatry, Birmingham, United Kingdom

AUTHORS
1. Ruth L Brand Flu¹, Dr, MD, amazonicalpha@aol.com

Until recently the general view in many countries has been that personality disorders are untreatable. However, the theme of dangerousness and burden to society has increasingly become a hot topic by the media, which has been influential in a shift of thinking towards an inpatient model of management. Proposals to get them locked up only for containment has been rejected eventually and gradually psychotherapeutic approaches are increasingly suggested. However, there is still too little know-how to deal with this large group of patients in the community and due to lack of public in patients units private hospitals are taking over this responsibility. However, intense supervision to communities- as discussed at a world conference dynamic therapy, 2007 illustrated that intense supervision in the community, including at homes can have an additional therapeutic effect to psychotherapy and behaviour management. There are ethical dilemmas of ostracising this group of patient by focusing predominantly on inpatient containment.

The debate is whether it can be considered more user friendly by empowering communities to deal effectively with this group of patients whilst enhancing the therapeutic outcome. How to motivate communities and policies to embark on such a journey can be considered a worthwhile discussion point.

COVERT COLLUSIONS IN THE TREATMENT AND CARE OF AUTISTIC SPECTRUM DISORDERS

INSTITUTIONS
1. St Stephen’s Centre, Learning Disabilities, Birmingham, United Kingdom

AUTHORS
1. Ruth L Brand Flu¹, Dr, MD, amazonicalpha@aol.com

Background:
Like psychotic and personality disordered individuals, people on the autistic spectrum can also evoke extremely strong and infectious reactions. Studies on parental reactions to neonates problematic interactions and controls revealed early recursive reactions. Different presentations at different settings can induce fragmentation of care.

Aims and goals:
Exploring reactions to outpatients on the autistic spectrum

Method:
Naturalistic study of all children and adult patients on the spectrum
Observations of carer’s and professional’s input towards the studied population. Spontaneous remarks of the professional /carer about their reactions, case notes

Diagnostic instruments were the ICD-10 criteria and PDDMRS (Pervasive Developmental Disorder Mental Retardation scale) backed up by the DISCO (Diagnostic Instrument for Social and Communication Disorders) regarding complex cases

Results:
57 patients so far. M/F47/10. 6/57 had normal intelligence. 22 had a late diagnosis (from late adolescence).

Reactions were:
Extreme fragmentation of care: 33/57 (57.9%), isolation: (22/57 (38.6%), extreme sense of aloneness: 23/57 (40.3%), over protectiveness, obsessiveness: 14/57 (24.6%), Wariness: 26/57 (45.6%).
Neutral interaction: 27/57 (46%).

Conclusion:
The findings of this pilot study should be further explored by a more scientifically astute research project. Aloneness and extreme fragmentation of care appears to be directly evoked by the condition. Wariness is highly correlated with degree of aggression of the patient. Abolition of aggression, respite and education diminish evoked reactions. Vigilance is required on covert collusions by professional and non-professionals in the treatment of the autistic individual. Children and adults will be processed separately

CRUELTY TO ANIMALS IN MULTI-EPISTEMIC SADISM

INSTITUTIONS
1. Scientific Center Of Treatment and Rehabilitation "Phoenix", Psychiatry, Rostov-on-Don, Russian Federation
2. Serbskiy National Research Center, Forensic Psychiatry, Moscow, Russian Federation
3. Southern Illinois University School of Medicine and Chester Mental Health Center, Psychiatry, Chester, IL, United States

AUTHORS
1. Olga A Bukhanovskaya¹, Dr., MD, PhD, Olgabux@yandex.ru
2. Alan R Felthous², Dr., MD, PhD, ARFel@aol.com
3. Alexander O Bukhanovsky¹, Dr., MD, PhD, bux@jeo.ru
4. Boris V Shostakovich², Dr., MD, PhD, bux@jeo.ru

Aims: research of role cruelty to animals in multi-episodic sadism.
Methods: clinical and psychopathological. Results: Examined have been 57 men who committed 2 and more violent sexual attacks, 37 serial killers among them. Steady repeated cruel aggression to animals (CA) was found in 19 cases (33.3%). It always first appeared at the age of 5 to 11. CA was mainly aimed against small domestic animal. The choice of the victim was spontaneous, depending on the animal's accessibility; exclusion of disturbing or hindering factors and personal negative account of disgust, aversion, abhorrence ("mangy", "ugly"), annoyance and anger. CA was manifested as repeated episodes of multiple, crude, destructive, physical, torturing, stereotypical impact on the animal, causing injury and death, further mockery of the body, sensation of rule and command. The ways of impact were contacting. No distant (fire), thermal, electric impacts have been registered.
Signs of dependant behavior were discovered. Typical were erotization and sexual deeds. CA was obsessive-compulsive. Its manifestations and consequences differed during pre-episodic and intra-episodic periods. The brutality of aggression grew with time.

Conclusions: In a number of cases CA is an early stage of cruel sadism appearance and development. The 2 types of obsessive-compulsive CA are: pre-episodic, which determines CA episode beginning, and intra-episodic, which determines multiple, stereotypical character of the deeds and a growing level of cruelty within the episode.

3. Aalia Al-Barwani¹
4. Nancy Zaki¹
5. Grigori Ostrovskiy¹

In today's world of rapid globalization, there has been a significant increase in the number of first time expatriates. Expatriation involves multiple changes in career prospects, social, cultural and environmental change and separation from family and friends. All of these are significant life stressors which can cause major distress and high incidence of depression and adjustment disorders in expatriates (1).

The aim of this study is to examine the psychological distress caused by expatriation and related factors in an educated homogeneous group of 171 university faculty members who have expatriated to Qatar to teach in one of the five American Universities. We prepared a socio-demographic questionnaire and utilized the 12-item General Health Questionnaire (GHQ-12) which has been widely used for detecting psychological morbidity over past few weeks. Factors such as age, sex, duration of stay, Educational Institution, marital status, presence of wife/children, Arabic, previous expatriation experience, intention to stay, and extent of socialization with Qataris were examined. Subjects age <35, never married, and who reported not being settled in Qatar had GHQ scores above the median score, indicating above average psychological distress. Higher scores were correlated with non-intention to repeat the experience and an intention to stay a shorter duration. There was also statistically significant association with the Institution where the faculty member works. The Institution environment is important in the psychological well-being of expatriate faculty. Also risk factors of young age, being single, and a subjective feeling of being unsettled are important risk factors for mental distress.

SHOPPING FOR MENTAL HEALTH CARE: LESSONS TO BE LEARNT FROM BANGLADESH

INSTITUTIONS
1. University College London, United Kingdom

AUTHORS
1. Alyson Callan1, Dr, MRCPsych, PhD, alysonf22@msn.com

AIMS
To explore pathways into psychiatric care, including the use of Western biomedical and traditional practitioners, and satisfaction with mental health care in Sylhet, Bangladesh.

METHODS
25 months of ethnographic fieldwork in urban and rural areas.

RESULTS
In cases of mental illness lasting longer than 4 weeks, patients and their families consulted a wide range of healers including Islamic healers, Hindu counter-sorcery specialists and Western biomedical doctors; a psychiatrist was almost always consulted. Traditional healing did not necessarily represent the cheapest option and was often much more expensive than consulting a psychiatrist. Dissatisfaction was expressed with all types of treatment. However, treatment was not sought outside Bangladesh, as is often the case for physical ill health.

CONCLUSION
Bangladesh, like elsewhere in South Asia, is medically pluralistic. Having a wide choice of mental health services does not necessarily lead to high satisfaction with care.

“MY NIECE IS A HERO”- CLINICAL CASE AND REVIEW ON GLOSSODYNIA

INSTITUTIONS
1. Hospital Magalhães Lemos, Portugal
2. Liaison Psychiatry Unit-HGSA, Portugal
3. Dermatology Unit-HGSA, Portugal

AUTHORS
1. Alexandra Cavalheiro1, dexterhard@yahoo.com
2. Monica Caetano
3. Alice Lopes

PURPOSES:
When complaints such as a localized discomfort as burning in the intra-oral area, with no physical findings appear, a great differential diagnostic workup is needed. Sometimes misunderstood by clinicians, the burning mouth syndrome or Glossodynia has a confusing terminology, and an absence of clear diagnostic criteria.

Is Glossodynia a somatiform disorder? Has characteristics for consider it as a mental disturb? Are the psychological symptoms comorbidity factors?

The authors present a case study with special interest to the clinical study of Glossodinia or Burning Mouth Syndrome, and its differential diagnoses, proposing a clinical review.

Clinical Case:
A 66 years old female, widow, with 2 sons, presenting burning mouth sensation for the last 4 years and anxiety for a longer time. This woman played a leading role on his family issues. Investigated by dermatology, she was sent to Liaison Psychiatry consultation. What dialogues can be created between Dermatology and Psychiatry? In what circumstances can we think this as a psychiatric condition? What medical investigation can lead to the treatment? The authors propose to discuss the clinical report.

CONCLUSIONS:
The etiopathogenesis of Glossodynia or Burning Mouth Syndrome seems to be complex and in a large number of patients involves interactions among local, systemic and/or psychogenic factors. In the idiopathic glossodynia patients present an important somatospsychic factors, and for that psychoactive drugs may be used. Some author’s propose the newer serotonin uptake inhibitor in case of depression or depression equivalents also known as “masked depression” or “smiling depression”. The use of psicotherapy is proven efficacious.

ASSESSMENT-TO-TREATMENT TOOLS IN DUAL DIAGNOSIS: INSIGHTS FROM THE FACE©-PROGRAMME

INSTITUTIONS
1. Vrije Universiteit Brussels, Psychology and Educational Sciences, Brussels, Belgium
2. Hospital Simone Veil, Psychiatry, Paris, France

AUTHORS
1. Smadar Celestin-Westreich, Prof. Dr., PhD, Smadar.Westreich@vub.ac.be
2. Leon-Patrice Celestin, Dr., MD, celestinlp@celestin.info

Background: Mental health care to addictive persons with a dual diagnosis of ADHD/Bipolar Disorder faces specific assessment and treatment challenges, resulting from the cumulative impact of these difficulties on their cognitive, emotional and neurobiological functioning.

Method: As part of the multi-site FACE© program (Facilitating Adjustment of Cognitions and Emotions), this paper presents evidence-based tools developed to respond to this challenge. The effects of implementing standardised ‘assessment-to-treatment’ tools are analyzed regarding diagnostic and treatment phases with a series of dual diagnosis addictive clients.

Results: Regarding assessment, systematic implementation of an in-depth multidimensional, evidence-based anamnestic protocol brings forward previously unidentified diagnostic information (e.g. illnesses, family load, suicide risks and childhood trauma) that is crucial to designing informed medication and care pathways consistent with international best-practice recommendations. Regarding treatment, this protocol appears to foster the client-practitioner relationship and the initiation of a therapeutic contract. Furthermore, clients’ active roles in applying ‘assessment-to-treatment’ tools such as observational agendas with contingency analyses of their cognitive-emotional regulations of substance craving, facilitates monitoring of addictive and disorder-specific responses. Early integration of psycho-education sessions with self-monitoring strategies, further benefits comprehension and differential control of multiple disorder challenges by clients.

Conclusion: Evidence-based, standardized ‘assessment-to-treatment’ tools are found to provide valuable insights regarding intertwined disorder dynamics in the context of addictive dual diagnosis clients. Multiple care challenges are thus met by simultaneously providing diagnostic and process-oriented therapeutic data. These also facilitate clients’ differential symptom insights and cognitive-emotional regulation. Further research and practice implications are discussed.

AIMS/OBJECTIVES
A description of a new therapeutic approach for Pathological Gambling

METHODS
After a psychiatric interview, aimed to evaluate the patient’s psychopathology and the eventual need for a pharmacological therapy; patients are enrolled in a group rehabilitation and psychotherapeutical program, which shows some innovations:
- Day Hospital setting;
- Short duration (20 sessions);
- Integration, continuity and contiguity of the 12-step Gamblers Anonymous and a psychodynamic group psychotherapy.

The program is proposed to all of our patients; it is an open group with a predefined termination for each participant. Groups are made of five to ten patients; each session lasts 90’; sessions are held twice weekly, alternating a psychodynamic and a GA-like meeting, lead respectively by a psychotherapist and an ex-gambler councillor.

This short-term intervention is designed as a passage from addiction to a long term treatment, through remission and the acquisition of a new insight.

RESULTS
36 patients joined the program. 20 of them completed treatment, 10 dropped out while 6 are in treatment at the moment. Of the 20 who completed treatment, only two are in a state of complete remission, while 18 were able to reach a state of partial remission. At the completion of treatment, 18 patients out of 20 went on with some kind of psychological therapy: 9 are involved with Gamblers Anonymous, 5 with a group psychotherapy, 4 with an individual psychotherapy.

CONCLUSIONS
An intensive short term rehabilitation program could be an effective tool in the treatment of pathological gambling, aiming to interrupt the dysfunctional behaviour and to start a more specific therapeutic setting.

RORSCHACH ASSESSMENT AND CORRELATION WITH ALEXITHYMIA IN A SAMPLE OF PATHOLOGICAL GAMBLERS

INSTITUTIONS
1. Università Cattolica del Sacro Cuore, Istituto di Psichiatria e Psicologia, Roma, Italy

AUTHORS
1. Annamaria Di Gioia
2. Corrado Villella
3. Massimiliano Pomponi
4. Gianluigi Conte, Dr., MD
5. Carlo Saraceni

AIMS/OBJECTS
In order to provide a better description of the psychodynamic aspects of pathological gamblers, the patients acceding our Psychiatry Day Hospital requiring treatment were assessed through Rorschach test and TAS-20 (Toronto Alexithymia Scale)

METHODS
After a psychiatric interview, twenty patients responding to the DSM-IV-TR criteria for Pathological Gambling were evaluated with the Rorschach test and the TAS-20. Rorschach tests were signed according to Klopfers method.

RESULTS
Preliminary results regarding twenty patients have shown the following features: a discrepancy between high ambition and real intellectual skills; a psychic life condition dominated by immature resources and impulses; an inappropriate self-control which is performed through emotional distance and experiences of deep anguish. Furthermore these subjects have found Rorschach inquiry difficult. These features can be indicative of a trouble in expressing emotions, according to alexithymia construct. Most of the patients were found to have significantly higher levels of alexithymia at Tas-20. This outcome is in accordance with previous works on the topic.

CONCLUSIONS
Our preliminary observations suggest to focus therapy not only on communication contents, but also on the communication style of the patient. These results also suggest that could be important to help patient to recognize and discriminate emotional conditions to prevent relapses due to out-of-control or repressed emotions.

PSYCHOPATHOLOGY OF VERBAL HALLUCINATIONS: MECHANISM, EXPERIENCE AND NARRATIVE

INSTITUTIONS
1. Federal university of rio de janeiro, institute of psychiatry, Rio de Janeiro, Brazil

AUTHORS
1. Octavio Domont De Serpa, Dr., MD, PhD, domserpa@gmail.com
2. Erotildes Maria Leal, Dr., MD, PhD, eroleal@uol.com.br

Objective: The purpose of this study is to discuss the reach and compatibility of main contemporary approaches - cognitive and phenomenological - that take verbal hallucinations as a self-consciousness disorder, having as criterion of evaluation the place given to the subjective experience.

Methods: On one hand the authors present a conceptual review of the central self-monitoring model and of the action self-ascription model, both methods standing from a third-person perspective concerning the verbal hallucinations. On the other hand they also present a conceptual review of the main contemporary phenomenological approaches, concerning the verbal hallucinations from a first-person perspective. The phenomenological approach is subdivided in two groups: one stresses the experiential dimension and the other the narrative dimension. Besides this conceptual review, the authors illustrate the lived experiences of verbal hallucinations with excerpts taken from voice hearers group developed in the Institute of Psychiatry of the Federal University of Rio de Janeiro.

Results: The mechanistic view that issues from the neurocognitive approaches gives us many empirical findings that help to naturalize this kind of symptom. However, it keeps us apart from the subjective dimension of the psychopathological phenomenon, essential to all clinical practices. To close this gap, a phenomenological approach is needed to gain access to the lived experience and to understand its personal meanings.

Conclusions: This study demonstrates the need to integrate third and first-person perspectives in psychopathological research and in clinical practice in the psychiatry field through the example of the psychopathology of verbal hallucinations.

DIAGNOSIS OF PERSONALITY DISORDERS AND SELF-HARM BEHAVIOUR

INSTITUTIONS
1. VMA-Sofia, Psychiatry, Sofia, Bulgaria
2. VMI-Pleven, Psychiatry, Pleven, Bulgaria

AUTHORS
1. Jordan Ganev¹, Dr, MD
2. Vladimir V. Nakov², Dr, MD, vnakov@gmail.com
3. Tony S Donchev¹, Dr, MD, PhD, tonyd@abv.bg
4. Hristina Martinova¹, Mrs

The self-harm behavior is a phenomenon related to a large spectrum of intrinsic, social and economic factors. Identification of self-harm behaviour like a marker of adaptation is related to specific psychiatric pathology. The distinguishing of that notion as one of the indicators for adaptation ability from truly medical epidemiological indicators is related to the identification of specific psychiatric pathology in most percentage of the cases this is pathology of personality. 457 persons were examined in total, classified in 3 groups.

Soldiers 178, students 94 persons from different universities in Sofia. The age in the examined group varies between 18 and 40. The average age in different groups is: clinical 21; students 23; soldiers 20. From the whole extract 82% are male gender and the rest 18% female.

The final model can be written in the following formula where \( p \) is suicide attempt: its prognostic possibility is 90.8% which must be interpreted as high. As this can be seen from the results, the highest risk of suicidal behaviour is for personality dimensions which might be put together under common name impulsiveness. There is a high risk from recidivism of the suicidal act at these dimensions determined as well as the basic characteristics as the fact that personality disorders are conditions comprising together deeply deposited and enduring models of behaviour which are expressed in a rigid manner of reaction towards a wide diapason of personal and social situations.

ANXIETY, DEPRESSION AND MEDICAL HISTORY IN PATIENTS WITH CUTANEOUS FACTITIOUS DISORDER AND IN THEIR SIBLINGS

INSTITUTIONS
1. University Hospital Farhat Hached, Psychiatry, Sousse, Tunisia

AUTHORS
1. Yousri El Kissi¹, Dr., MD
2. Nesrine Kenani¹, Dr., MD
3. Amel Mebazza¹, Dr., MD
4. Selma Ben Naas², Pr., MD
5. Mohamed Denguezli¹, Pr., MD
6. Rafiâa Nouira¹, Pr., MD
7. Béchir Ben Hadj Ali², Pr., MD

Cutaneous Factitious Disorder (CFD) is characterized by artefactual skin lesions with denial of self-infliction. The medical past history of CFD patients sometimes reveals a physical illness or disability with long periods of hospitalization and dependency on hospital staff. Besides, a background of emotional disturbances such as anxiety and depression with feelings of isolation and insecurity is often observed.

Objective
The aim of this study was to compare anxiety, depression and medical past history in patients with CFD and in their siblings.

Methods
It's a comparative study held in dermatology and psychiatry departments of the university hospital Farhat Hached (Sousse, Tunisia). Thirty female patients diagnosed as CFD according to DSM-IV criteria were prospectively recruited. The siblings group consisted of their age matched sisters. Assessment was based on medical personal history, psychiatric antecedents and HAD-S anxiety and depression scores.

Results
CFD patients and their sisters were respectively 30±8.9 years and 30±6.1 years old. They had the same social and family conditions and educational level, but CFD patients were more often celibates \( (p<10^{-4}) \) and out of work \( (p<10^{-4}) \). They also had more personal hospitalization and dependency on hospital staff \( (p=0.02) \), more psychiatric antecedents \( (p=0.06) \) and more previous suicide attempts \( (p=0.01) \). HAD-S measures showed higher depression \( (p<10^{-4}) \) and anxiety \( (p<10^{-4}) \) scores in CFD patients.

Conclusion
In spite of similar family and social conditions, patients with CFD had more past medical antecedents and higher anxiety and depression scores than their siblings. These emotional disturbances may explain why they inflicted themselves skin lesions.

AUTHORS
1. Virgil V. Enatescu¹, Prof., MD, PhD, virgilenatescu@yahoo.com
2. Virgil Radu V. Enatescu², Dr., MD, renatescu@yahoo.com

Aims/Objective: We have the experience of 30 years of objectivi-
zation, analog-digital translation, automatic processing, graphical
representation, pattern recognizing for the dynamic of the human
gait, the patterns of the gesture models, variations of dynamic of the
writing and of the physical pattern of the voice, applied in psychi-
atry.

Methods: The instrument we used are: original traductors, systems
of calculation and programming belonging to the artificial intelli-
gence which create new pattern of representation of the gait, gestu-
re, sonorous background of the speech, the dynamic of the writing
which can be represented or through a matrix or in a n-dimensional
space on specific clusters or to some human typology or to some
psychical disorders.

Results: There is the chance for a new semiology which has objective
paraclinic value for psychiatry field of automate analyses, nonverbal
behavior parameters named by us “Extraverbale Analysis”.

Conclusions: Handwriting’s pathography in psychiatry is very consi-
stent especially during the classical psychiatry period, when the lack
of paraclinic diagnostic tools imposed to extend the investigations
to objective elements of diagnostic. The pathology of non-verbal
expression includes several studied elements. But all acquired know-
ledge has the deficiency of subjective descriptive and metaphorlic
describing, without a precise determination of objective parameters
which could be accessible to automatic processing on computer
with a bigger volume of data which can make them efficient in cli-
nical practice and research. We present techniques of objectivisa-
tion resulted till now and future possibilities of using them. The
workshop wants to be an opening to this new objective domain.

ASSESSMENT OF CASES USING “THE MIGRATORY STRESS
AND GRIEF ASSESSMENT SCALE”

INSTITUTIONS
1. University of Barcelona, SAPPIR, Barcelona, Spain
2. IAS Gerona, Psychiatry, Gerona, Spain
3. University of Barcelona, Personality, Barcelona, Spain

AUTHORS
1. Joseba Achotegui¹, Mr, MD, sappir@terra.es
2. Dori Espeso², Mrs, MD, sappir@terra.es
3. Ana Maria Tuset³, Mrs, PhD, sappir@terra.es

Cases of immigrants are studied, analysing their symptoms in relati-
on to the migratory stress and grief experienced, using the MSGAS
based on psychoanalytical and cognitive approaches (Achotegui
2006). This scale is characterised by
1. The grouping of migration stress factors into 7 types of grief.
2. The classification of these types of grief into simple, complicated
and extreme, depending on their preparation difficulty
3. Assessment of subject vulnerability and the intensity of the stress
factors

Symptoms would be an element associated to these situations that
may be correlated with the scale. The version of the scale presented
is a modification of a previous scale model (Achotegui 1997)

GRIEF VULNERABILITY INTENSITY OF STRESS FACTORS
I. The family Simple Simple
   Complicated Complicated
   Extreme Extreme
II. The language Simple Simple
    Complicated Complicated
    Extreme Extreme
III. The culture Simple Simple
    Complicated Complicated
    Extreme Extreme

IV. The earth Simple Simple
    Complicated Complicated
    Extreme Extreme
V. Social Status Simple Simple
   Complicated Complicated
   Extreme Extreme
VI. Group of belonging Simple Simple
    Complicated Complicated
    Extreme Extreme
VII. Phisical risks Simple Simple
     Complicated Complicated
     Extreme Extreme

NOTE. NUMBER OF:
- SIMPLE GRIEFS:
- COMPLICATED GRIEFS:
- EXTREME GRIEFS:

The results show the existence of clear correlations between the
experience of complicated and extreme grief and the symptoms.

ULYSSES SYNDROM IN INMIGRANT MINORS

INSTITUTIONS
1. IAS Girona-SAPPIR Barcelona, Child Psychiatry, Girona, Spain

AUTHORS
1. Dori Espeso¹, Dr., MD, 36221dem@com.es

This exposition covers the concept of chronic and multiple stress relating to the immigrant infant-youth population. Chronic stress and its pervasive nature with a bearing on the generation of psychosomatic illnesses are analysed, inevitably leading to the need to take preventative aspects and the importance of social capital in the development of mental illness into account. We shall comment on the factors forming stress and aspects involving chronic levels, multiplicity and the loss of control over stress factors. We shall mention the resilience and health promotion models from a clinical and welfare viewpoint.

BULLYING: A SCHOLAR EXCLUSION FACTOR

INSTITUTIONS
1. Centro Universitário Metodista IPA, Post Graduation, Porto Alegre, Brazil

AUTHORS
1. Ygor A Ferrão¹, Dr., MD, PhD, ygorafer@terra.com.br
2. Sumaia F Curço¹, Mrs., familiacurco@terra.com.br
3. Marlis M Polidori¹, Mrs., MD, PhD, marlis.polidori@metodistadosul.edu.br

Introduction: The school violence is a consequence not only of the social context, but also of its own educational process and specific relationship phenomena. One of these phenomena is the so called “Bullying”, which leads some students to a kind of social exclusion and its consequences. Objectives: to better understand the risk factors and the consequences of bullying phenomena.

Method: this pilot qualitative case study included 14 to 17 years old students from two private schools in Porto Alegre, Brazil. Eleven students were directly interviewed; five observations during the class and two during the class-interval were conducted.

Results: in the school A, homosexualism and relationship problems were cited as risk factors, while in the school B, homosexualism and socioeconomic differences were cited. In both schools, the students cited repetitive aggressive verbal jokes as the main bullying factor, leading to different degrees of suffering, and the students to move to other classroom (if possible) or even to other school. The students believe the schools are not able to resolve bullying, and that teachers are not enough compromised to interrupt the process.

Conclusion: bullying is a universal process that occurs even during the class. Repetitive aggressive verbal jokes are the main bullying instruments and its content generally includes sexuality and socioeconomic differences. The schools’ and teachers’ initiatives absence to stop bullying can be a risk factor of its maintenance.

AUTHORITARIAN PERSONALITY TRAITS IN IRANIAN MEDICAL STUDENTS

INSTITUTIONS
1. Shiraz university of medical sciences, Psychiatry, Shiraz, Iran (Islamic Republic of)

AUTHORS
1. Ali Firoozabadi¹, Dr., MD, firooz@sums.ac.ir
2. Mohammad Jafar Bahredar¹, Mr., Msc, psychat@sums.ac.ir

Background: Adorno and his colleagues made an attempt to describe the behavior of people in the pre-war era in Germany. Their research led to the introduction of F-scale which is used as a measurement for conservative and authoritarian attitudes. Objective: By the use of F-scale, we tried to evaluate authoritarian traits in a group of Iranian medical students in Shiraz University of Medical Sciences. Socio-economic status of the present-day Iran is comparable to pre-war era in Germany. Method: 80 medical students (40 men and 40 women) in different years of education were randomly selected and evaluated by the questionnaire. By statistical analysis, authoritarian traits were compared between male and female students and also in different years of education (First year, 3rd year and internship).

Results: Female students showed a higher score than the male students. Also, we found a trend for male students to become more authoritarian over time. For the female students an opposite trend was found. Conclusion: These results could be representative of different attitudes of male and female students toward authority related issues. Also, it could be in favor of different effects of education on authoritarian traits among the male and female.

HOW STRONG IS TENDENCY TO FAKE GOOD ON AMORALITY MEASURES?

INSTITUTIONS
1. Institute of Mental Health, Serbia and Montenegro
2. School of Medicine, University of Belgrade, Serbia and Montenegro
3. Department of Psychology, University of Belgrade, Serbia and Montenegro

AUTHORS
1. Dejan Florikic¹
2. Ivana Perunicic¹
3. Dusica Lecic Tosevski¹,²
4. Goran Knezevic³

Objective: The aim of this study was to detect dishonest subjects who deliberately show themselves in socially acceptable manner while being assessed by some psychological instruments. Method: The sample consisted of 80 subjects (40 non-psychotic patients and 40 graduate high school students) to whom the test Amoral-15 (measuring antisocial tendencies within three general factors of amorality: amorality which rise from impulsivity, frustrations and brutality) was administered in two different situations - with the standard Instruction (E1) and with the instruction to fake (E2). The (E1-E2) difference is taken as an objective measure of ability to fake good. Results: Results showed that not all of the subjects are able to present themselves in socially acceptable manner even when they are told to do so. Namely, 25% subjects worsened their result while 50% of them showed the same result which they reached under the standard instruction (E1). Another 25% subjects improved their result but not in the way which can jeopardize the rank of subjects who are at the bottom on the Amoral-15 scale. The subjects most easily hide their impulsivity, low control, hedonism, weak socialization and laziness, while they have difficulties in hiding their projections and rationalizations.

Conclusions: The construction of the items which do not judge the transgressions and moral tendencies is helpful in giving positive responses and thus make the Amoral-15 scale resistant to the possibility of giving social desirable answers.

SEXUAL BEHAVIOR CHANGE IN DOMINICAN UNIVERSITY STUDENTS

INSTITUTIONS
1. Autonomous University of Santo Domingo, School of Medicine, Institute of Human Sexuality, Santo Domingo, Dominican Republic
2. Columbia University, Public Health, New York, United States

AUTHORS
1. Rafael A Garcia, Dr., M.D., PhD, raf.garcia@codetel.net.do
2. Cesar Mella, Dr., M.D., inst.sex.humana@codetel.net.do
3. Ian Holloway, Mr., B.A., inst.sex.humana@codetel.net.do
4. Ramon Almanzar, Mr., M.Sc., inst.sex.humana@codetel.net.do
5. Fidel Valera, Dr., M.D., inst.sex.humana@codetel.net.do
6. Antonio De-Moya, Mr., MPH, inst.sex.humana@codetel.net.do

Objectives: The present study analyzed the effectiveness of an STD/HIV prevention program delivered by the Institute of Human Sexuality (IHS) at the Autonomous University of Santo Domingo (AUSD). This project attempted to assess likely differences in knowledge, attitudes and sexual behavior between students who participated in the program and those who did not.

Method: During the summer session of 2006, a self-administered questionnaire was given to 190 intervened students and 897 control students. The questionnaire measure sociodemographic, sexual experience and behavior, condom use and attitudes about condoms (1, 2).

Results: Statistically significant effects between intervention and control groups (p<0.05) were found regarding four key variables. Median self-reported STD knowledge was higher among intervention group than in the control (3.5 vs 3.1). Median number of sexual partners was lower among intervention group than control group (0.8 vs 1.1). Two thirds (66.7%) of intervened students reported using a condom at last intercourse compared with 46.5% of those in the control group. Median scores on attitudes toward condom use were significantly more favorable in the intervention group than in the control (23.4 vs 20.9). Multiple regression analysis demonstrated that these results were independent of gender or formal studies in the health sciences.

Conclusions: University students in the DR are at elevated risk for STD/HIV infection. The intervention program implemented by IHS is effective in influencing several important factors that have been shown to affect STD/HIV transmission, including positive attitudes toward condoms and use of condom at last intercourse. Recommendations for program improvement and dissemination are made.

3. Alexandros Gerontas
4. Matthaios Sardis
5. Nektarios Drakonakis
6. Ersi Tsapanaki
7. Konstantinos Kontis

AIMS: To track, analyze and group the graphological disorders of patients with severe psychiatric disease. Relating such disorders with psychiatric symptomatology would enable us evaluate the effectiveness of the treatment administered and correlate a patient's recovery with changes in graphological findings.

METHODS: Two samples of handwriting have been collected from 100 inpatients with major psychiatric disorders who met DSM-IV criteria for schizophrenia, depression and bipolar disorder. The first sample was collected at admittance (acute phase) and the second at discharge (remission phase). The sample collection took place under specific conditions. Sample analysis included: an assessment of 175 graphological signs and 7 graphological genera (speed, pressure, size, direction, form, sequence and page structure), an interpretation of these graphological signs, a composition of a graphological portrait for each patient and a correlation of all the above with his medical history and psychiatric diagnosis.

RESULTS: The analysis of the graphological data mentioned above, demonstrated a significant influence in formative graphological features such as size, direction, writing pressure, form and page structure during the acute phase, whereas the remission phase was followed by an improvement in all these parameters, including the general structure of handwriting.

CONCLUSION: Graphology could be utilized and cooperate with Psychiatry. We consider it to be a valid and useful tool -among others- in the assessment of the clinical picture of psychiatric patients and the evaluation of their response to therapy.
CASE REPORT: SEVERE SELF-MUTILATION WITHOUT BORDERLINE PERSONALITY DISORDER

INSTITUTIONS
1. University of Sao Paulo, Psychiatry, Sao Paulo, Brazil

AUTHORS
1. Jackeline Suzie Giusti1, Mrs, MD, jsgiusti@yahoo.com.br
2. Anna Karla Garreto1, Mrs, akgarreto@yahoo.com
3. Hermano Tavares1, Mr, PhD
4. Euripedes Constantino Miguel1
5. Sandra Scivoletto1

Self-mutilation behavior (SMB) is considered to be a common clinical behavior among individuals with Borderline Personality Disorder (BPD) and as part of Impulse-Control Disorders criteria. This case report describes a 24-year-old woman with severe SMB, without BPD. The patient was admitted to the multiple impulse-control disorder outpatient unit for treatment of SMB. This patient was submitted to the SCID-I/P, SCID-II/P, Y-BOCS, DY-BOCS, Functional Assessment of Self-Mutilation (FASM), and USP-SPS, this last questionnaire was designed to assess the kinds of subjective experiences that may precede or accompany some repetitive behaviors, compulsions and tics. The more frequently SMB presented was skin cutting which was associated with relieving feelings of "numbness"; self-punishment; feeling something (even pain); feeling relaxed; and stopping bad feelings. Others comorbidities presented by her were Obsessive-Compulsive Disorder (OCD) with predominance of compulsive over obsessive behaviors, Social phobia, Bulimia, Depression Disorder (DD) with high levels of anxiety, and avoidant personality disorder. The characteristics on SCID-II/P were not enough for BPD diagnosis. Subjective experiences of tactile sensations, "visual just-right perceptions", and "urge only" (an inner sense that she "have to" do it) were related to SMB rituals, as well as preceded the compulsive behaviors, at the USP-SPS.

Conclusion: This case raises some questions: Would this case be an atypical kind of SMB, without BPD, or a nosologic entity with its own characteristics, where OCD comorbidity is frequent? Would SMB be a symptom of OCD that increases its severity? More studies will necessary to answer these questions.

AURICULAR ACUPUNCTURE IN DUAL DIAGNOSIS: RANDOMIZED CONTROLLED PILOT TRIAL

INSTITUTIONS
1. Abarbanel Mental Health Center, affiliated with the Sackler School of Medicine (Tel Aviv University), IDDTW, Bat Yam, Israel

AUTHORS
1. Eran Goldstien1

3. Yuri Gimelfarb1
4. Zipi Natan1
5. Sabry Elwahidi1
6. Elionora Kaikov1

BACKGROUND AND AIM:
The auricular acupuncture (AA) detoxification was first introduced in 1974. Over the past thirty years this technique has been extensively studied and improved. Unfortunately, there is no empirical evidence to recommend the use of AA for dual diagnosis patients (DDP). The absent data on the efficacy and safety of the AA leads to inappropriate use of this therapeutic intervention in DDP. This trial aimed to investigate the effectiveness and safety of AA in DDP for the management of both psychiatric and addiction issues.

METHODS:
Randomized controlled parallel groups clinical trial: the study population group [10 AA treatments at least 20 minutes 4-5 times a week] comprised 12 subjects (11 males (91.7%), mean age 28.8 years (SD=5.7)), the control population group (without AA) comprised 3 subjects (3 males (100.0%), mean age 29.5 years (SD=7.8)). AGGRESSIVE BEHAVIOUR IN CANCER PATIENTS

INSTITUTIONS
1. Städtische Kliniken Frankfurt-Höchst, Psychiatry, Psychotherapy, Psychosomatics, Frankfurt / Main, Germany

AUTHORS
1. Michael Grube1, Dr., MD

Introduction:
Some of the in-patients on oncological wards do not meet the staff’s expectations in behaving compliant and show overt aggression.

Objective:
To describe frequency, quality, underlying variables, and the impact of aggressive behaviour on future cutting short from oncological in-patient treatment in cancer patients.

Group and Methods:
Investigation of 388 oncological in-patients in liaison-consultation psychiatry. Methods: Staff-Observation-Aggression-Scale-Revised (SOAS-R), Basic Psycho-Oncological Documentation (PO-BADO), intensity of pre-existing or cancer-induced psychiatric ailments (DSM-IV).

Results:
19 out of 388 (4.9%) patients showed overt aggressive behaviour (14: verbal aggression, 5: beating and/or kicking). Carcinoma induced psychiatric disorders, pre-existing DSM IV axis 1 psychiatric disorders, current function status, and male sex were correlated to overt aggressive behaviour. 11 out of these 19 patients showed organic psychiatric disorders (7 carcinoma induced and 4 pre-existing organic psychiatric disorders) with cognitive impairments (p = .000). 8 out of these 19 patients cut short from oncological in-patient treatment (p = .000). The predictive quality of overt aggressive behaviour for future cutting short from oncological in-patient treatment can be described with the help of Receiver-Operating-Characteristics (ROC): AUC 81.9 % (p = .000; sensitivity 66.7%, specificity 97.1%).

Discussion:
The results demonstrate that organic psychiatric disorders play an important role in aggressive behaviour of cancer patients treated as in-patients. Furthermore aggressive behaviour can be interpreted as a risk factor of cutting short future oncological in-patient treatment. As a consequence the staff working on oncological wards should be enabled to detect aggressive behaviour and its precursors as soon as possible.

P-02-087
BYPASSING THE BLUES: A TELEPHONE-BASED STEPPED COLLABORATIVE CARE TRIAL FOR TREATING POST-CORONARY ARTERY BYPASS GRAFT (CABG) DEPRESSION

INSTITUTIONS
1. University of Pittsburgh, School of Medicine, Pittsburgh, PA, United States
2. University of Pittsburgh, Department of Biostatistics, Pittsburgh, PA, United States

AUTHORS
1. Bea Herbeck Belnap1, Dr Biol Hum, belnapbh@upmc.edu
2. Fang Zhu2, MS, zhuf@upmc.edu
3. Sati Mazumdar1, PhD, maz1@pitt.edu
4. Charles F Reynolds1, MD, ReynoldsCF@upmc.edu
5. Bruce L Rollman1, MD, MPH, rollmanbl@upmc.edu

Background: Approximately 20-25% of post-CABG patients report elevated depressive symptoms. It is unknown whether effective treatment of post-CABG depression improves cardiovascular, economic, and other outcomes. Stepped collaborative care (SCC) for depression with active follow-up by a care manager following a treatment protocol and under physician supervision has been proven effective in primary care, yet never before applied to depressed cardiac patients.

Methods: We screened post-CABG patients for depression prior to hospital discharge with the two-item Patient Health Questionnaire (PHQ). If positive, we administered the PHQ-9 two-weeks later, and randomized those who scored >9 (depressed) to either their physician’s “usual care” or to an 8-month SCC protocol. To facilitate comparisons, we also randomly selected a cohort of non-depressed post-CABG patients (negative PHQ-2/PHQ-9<5).

Results: From 3/2004-9/2007: 2,486 patients completed the PHQ-2; 1,387 (56%) screened positive; 1,268 (91%) were protocol-eligible; 1,100 (87%) completed the PHQ-9; 337 (31%) scored >9; and 303 (90%) agreed to randomization. Their mean age was 64 (range: 36-91), 41% were female, 9% non-Caucasian, and mean PHQ-9 score was 13.5. Compared to non-depressed controls (N=152), depressed subjects were younger (64 vs. 66 years; p=0.04), reported lower mental health-related quality-of-life (SF-36 MCS 43.1 vs. 61.6; p=0.001), and were more likely to have COPD (20% vs. 9%; p=0.003).

Conclusions: Post-CABG depression is common and associated with certain sociodemographic and clinical features. As our study blind is active until 5/08, we will describe the impact of SCC for post-CABG depression on quality-of-life cardiovascular morbidity, work, and health services utilization at the conference.

A REVIEW OF SUBJECTIVE MEMORY IMPAIRMENT - THE NEED FOR A STANDARD DEFINITION

INSTITUTIONS
1. University of Birmingham, Department of Old Age Psychiatry, Birmingham, United Kingdom
2. University of Birmingham, Medical School, Birmingham, United Kingdom

AUTHORS
1. Khaled Abdurab1, Mr, kaa254@bham.ac.uk
2. Reinhard Heun1, Professor, r.heun@bham.ac.uk

Aims/Objectives:
Subjective Memory Impairment (SMI) may hold value in the elderly as a predictor of dementia. There is yet to exist any standard definition of SMI for use in research or for clinical practice. This study aims to identify previous and current definitions of SMI used in published research and to propose a set of criteria that may help increase SMI’s predictive power of future cognitive decline.

Methods:
Literature searches were conducted across a number of electronic databases including Medline.

Results:
515 citations were identified, 336 papers were obtained, of which 37 were selected for containing definitions for SMI. These definitions varied widely in terms of criteria and types of questions used.

Conclusion:
There is no consistency in how SMI is defined. We propose a set of criteria aimed to increase specificity of memory complainers for those at increased risk of dementia. Further research is required to refine and validate the different criteria suggested.

SYMPTOMS PRESENTATION IN PATIENTS WITH SCHIZOPHRENIA: COMPARISON IN 3 MALAYSIAN MAJOR ETHNIC GROUPS

INSTITUTIONS
1. Hospital Melaka, Department of Psychiatry and Mental Health, Melaka, Malaysia
2. Hospital Universiti Kebangsaan Malaysia, Department of Psychiatry, Kuala Lumpur, Malaysia
3. Hospital Kuala Lumpur, Department of Psychiatry and Mental Health, Kuala Lumpur, Malaysia

AUTHORS
1. Nurulwafa Hussain1, Dr, aufaira@yahoo.com
2. Osman Che Bakar2, Dr
3. Siti Nor Aizah Ahmad3, Dr

Aim: This is a cross-sectional study examining the difference of symptoms presentation among the Malay, Chinese and Indian patients with Schizophrenia.

Method: Patients aged between 18 to 64, diagnosed to have Schizophrenia in acute stage, admitted to psychiatric ward, Hospital Kuala Lumpur. The Structured Clinical Interview for DSM IIIR and DSM IV (SCID) and Positive and Negative Syndrome Scale (PANSS) were used to diagnose patient with schizophrenia, and to compare the difference in symptoms presentation, respectively.

Results: 97 patients, comprise of 48.5% Malay, 27.8% Chinese and 23.7% Indian were included in this study. The PANSS score on emotional withdrawal, tension and active social withdrawal were significantly high among the Indians as compared to the Malays and Chinese.

Conclusion: There was no significant difference on positive symptoms but there were significant differences of some negative symptoms and general psychopathology among the 3 ethnic groups. The data could provide as a preliminary finding for future other transcultural research in Malaysia.

PHENOMENOLOGY OF DELIRIUM: A FACTOR ANALYTIC STUDY

INSTITUTIONS
1. PGIMER, Psychiatry, Chandigarh, India

AUTHORS
1. Gaurav Jain, Dr., MD
2. Subho Chakrabarti, Dr, MD, MRCPsych, MAMS, subhochd@yahoo.com
3. Paramanand Kulhara, Prof, MD, FRCPsych, FAMS, param_kulhara@yahoo.co.in

Aims/Objectives: The phenomenology of delirium is not well characterized. Factor analysis could help in defining syndrome subtypes and suggest underlying pathophysiological or neuroanatomical bases for symptoms of delirium. The present study thus aimed to investigate the phenomenology of delirium by using a factor analytic technique.

Method: Eighty-six consecutive adult patients with a diagnosis of delirium according to DSM-IV-TR criteria and the adaptation of Confusion assessment Method scale were assessed using the delirium rating scale revised-1998, the Memorial Delirium Assessment Scale and the Confusion State evaluation within 7 days of onset.

Results: A two-factor solution provided best fit for the data. The first "global cognitive" factor comprised language disturbances, thought process abnormality, disorientation, inattention, short-term memory impairment, long-term memory impairment, disturbance of visuospatial ability, impaired consciousness, and perseveration. The second "psychotic-behavioural" factor consisted of sleep-wake cycle disturbances, delusions, perceptual disturbances including hallucinations, motor agitation, inverse of motor retardation, lability of affect, distractibility, irritability, impaired wakefulness and temporal onset of symptoms.

Conclusions: The two factors derived from this study support the validity of distinguishing delirium into two overlapping subtypes. The "acute confusional state" or hypoactive subtype (the "global-cognitive" factor of this study) can be defined by disturbances in consciousness and cognitive functions. On the other hand, the hyperactive subtype or "acute agitated delirium" (the "psychotic-behavioural" factor of this study) is defined by superadded hyperactivity, hallucinations, delusions, insomnia, etc. Such a classification of delirium can also prove useful in refining its nosology as well as understanding its neurobiological origins.

THE REVISION OF THE INTERNATIONAL CLASSIFICATION OF DISEASE, JAPANESE PERSPECTIVES

INSTITUTIONS
1. Tokyo Medical University, Department of Psychiatry, Tokyo, Japan

AUTHORS
1. Makio Iimori, Dr., M.D., Ph.D., iimori@tokyo-med.ac.jp
2. Toshimasa Maruta, M.D., M.D., Ph.D.,

The Japanese Society for Psychiatry and Neurology organized the ICD committee and has started to clarify the problems of the ICD-10 with regard to preparation for the ICD-11. In addition, the committee organized a comprehensive committee and committees in categories F1-F9.

The comprehensive committee is researching some potential problems like the number of major categories (like F1-F9), comorbidity issues, threshold of disorder and relationship between disability and disorder.

We are distilling the problems expressed by both the specific category committee and members of the Japanese Society for Psychiatry and Neurology using the web.

In this presentation, we report the present problems and recent suggestions by above mentioned methods.

A NEW STRATEGY FOR TREATMENT OF BORDERLINE PERSONALITY DISORDER

INSTITUTIONS
1. Independent Private Practice, New York, United States

AUTHORS
1. Yukio Ishizuka, Dr., MD, dri@lifetrack.com

Objective: To demonstrate that borderline personality disorder can be predictably overcome by transforming their personality through 'breakthrough intimacy' - closeness between committed couples far greater than their previous maximum experiences. The result of this study of 182 cases over the last 20 years supports an alternative approach in treatment of borderline personality disorder.

Method: This approach works with that patient and his/her partner, bringing them far closer than ever before, guided by their own daily self-rating on 41 parameters that allow accurate graphic tracking via Internet of subtle changes in their personalities and dynamic mental status. It frees the therapists from transference (and counter-transference) issues, which is the principal obstacle in treatment of borderline personality disorder. The therapist actively guide the couple to achieve closeness far greater than their previous maximum level, overcoming waves of symptom spikes until they disappear by exhaustion, as the couples undergo personality transformation.

Results: The patient couples typically go through four distinct stages, with stage IV representing complete transformation. Of the 182 diagnosis confirmed patients, 15% reached stage IV, 12% reached stage-III, and 12% reached stage-II at the time of termination. Of the 60% of patients who failed to reach stage-II, 75% were those who came without partners and remained alone through therapy. Therefore, if we count couples only, treatment results would be about twice better.

Conclusion: Symptoms of borderline personality disorder may be better understood and treated as consequences of one's personality, which can be transformed through 'Breakthrough Intimacy.'

ALCOHOL ABUSE IN SCHIZOPHRENICS AND ITS IMPACT FOR VIOLENT BEHAVIOR

INSTITUTIONS
1. Medical University Sofia, Psychiatry, Sofia, Bulgaria

AUTHORS
1. Vasil P Jenkov, Dr., MD, vassil_j@abv.bg
2. Radoslav Borisov, Dr., MD

BACKGROUND: Each alcohol abuse and schizophrenia have been found to be related to violent behavior in a number of studies. There has been much concern about the rates of violence among persons who exhibit more than one psychiatric disorder. It has been suggested that persons with schizophrenia and substance abuse problems are more at risk for the commission of violent offenses than are persons with either alone.

OBJECTIVE: To investigate the hypothesis that violent behavior is more common in schizophrenics who abuse alcohol.

METHODS: Subjects of research were 84 patients (57 men and 27 women) aged from 18 to 70 years, diagnosed by ICD-10 with Paranoid schizophrenia (F20.0) with similar pattern of course - episodic with progressive deficit - of whom 45 abused alcohol. They were investigated retrospectively using a semi-structured interview and BPRS scale - extended version. Data is investigated by the program for statistical analysis SPSS 13.0.1. ANOVA, crosstabulation, $X^2$ - analysis and Mann-Whitney U test have been made.

RESULTS: Significantly higher number of schizophrenics who abuse alcohol and have committed assaults. Significantly more are the acts of violation of property in alcohol abusing schizophrenics and arrests are more frequent in this group. It makes impression that male sex is 3.5 times more presented in the group of alcohol abuse and schizophrenia and twice more of the alcohol abusers have been separated from their parents in childhood.

CONCLUSION: Alcohol abuse in schizophrenia is related to higher rates of violent behavior than schizophrenia alone. Men were more predisposed to alcohol abuse than women.

5. Cem Ilнем, Dr, Assoc. Prof

Objective: Neurosyphilis (NSy), an infection of the CNS caused by Treponema pallidum may present with neuropsychiatric symptoms (1). The aim of this case report is to emphasize the importance of NSy being kept in mind in the differential diagnosis of psychiatric patients (2).

Method: A NSy case presenting as acute psychotic manic episode is described.

Results: A 37 year old male patient, psychiatric symptoms developing in the last 20 days. Delusions of grandiosity and elevated mood are the prominent features of the clinical picture. Serological tests revealed NSy and led to organic mood disorder diagnosis.

Conclusions: Syphilis is still a common STD, especially in developing countries, although frequent use of antibiotics has altered the natural course. This typical case of general paralysis should remind us of NSy as an etiological factor in psychiatric illnesses.

ARIZONA SEXUAL EXPERIENCE SCALE (ASEX)- PATIENTS WITH DEPRESSION

INSTITUTIONS
1. Hospital of Medical School, Psychiatry, Bratislava, Slovakia

AUTHORS
1. Dusan Kesicky, Dr., anexa@post.sk
2. Vladimir Novotny, Prof., PhD., anexa@post.sk
3. Melinda Kesicka, Mgr., anexa@post.sk

It is often necessary to find out promptly what phase of sexual cycle is the most affected in patients with depression. In the research sample of 67 participants (25 men, 42 women, average age 43.4 years) with diagnosis of F31.3, F31.4, F32.x, F33.x, we were finding out the influence of depression depth on changes in sexual desire, arousal ability, coital readiness, orgasmic ability and satisfaction using ASEX Inventory. By statistical analysis (basic, Pearson) in the group the significant influence of depression depth (Beck Depression Inventory and Hamilton Psychiatric Rating Scale for Depression) was found out most on decrease of sexual desire (p<0.001), less on arousal ability and coital readiness (p<0.01). Only the influence on extent of sexual desire is significant in men (p<0.001). In women the depression influences the most arousal ability and coital readiness, less significant influences sexual desire (p=0.05). Intersexual differences are statistically significant. The internal consistency of results is high (Cronbachs index alpha is 0.846) ASEX Inventory is useful screening tool for prompt specifying the influence of depression on particular phases of sexual cycle.

3. M. Kesicka

It is often necessary to find out promptly what phase of sexual cycle is the most affected in patients with depression. It's also useful in monitoring of antidepressive pharmacotherapy.

In the research sample of 67 participants we were finding out the influence of depression depth on changes in sexual desire, arousal ability, coital readiness, orgasmic ability and satisfaction.

By statistical analysis in the group the significant influence of depression depth was found out most on decrease of sexual desire, less on arousal ability and coital readiness. Only the influence on extent of sexual desire is significant in men. In women the depression influences the most arousal ability and coital readiness, less significant influences sexual desire. It was also used the GRISS Inventory (The Golombok-Rust Inventory of Sexual Satisfaction).

ASEX Inventory (The Arizona Sexual Experience Scale) is useful screening tool for prompt specifying the influence of depression on particular phases of sexual cycle. There are significant differences in changes in phases of sexual responsive cycle of men and women.

Objectives: to depict changes in emotional and social functioning in female patient (age 31) suffering from borderline personality disorder following outpatient Gestalt psychotherapy.

Methods: psychiatric interview, psychological testing at the beginning and after 50 sessions, and 75 Gestalt psychotherapy sessions through 3.5 years, focused on building up client-therapist relationship, improvement of awareness and self-esteem, personal responsibilities, building and preserving personal boundaries and integrity. The techniques were: conversation exercises, genogram, collage, drawings, Diary of awareness.

Results: patient said that she had come to the therapy because emptiness and sadness, sense of being on a border between life and death, everything was meaningless, her behaviour was often uncontrolled, she had been unable to establish a relationship for 7 years.

During the therapy the patient graduated from university after 12 years, bought her own apartment and moved away from her parents, kept permanent job and established deep, meaningful relationship and got married. The results of psychological re-testing showed improvement in overall functioning, significant reduction in social maladjustment, easier establishment of close relationships and increased trust. Personality structure remained well outlined, but with better control, more realistic insight and better social adjustment.

Conclusions: the patient was able to recognise better insight and control of her reactions, better social functioning, easier interpersonal contacts, achievement of the most important goals, awareness of personal boundaries and awareness of her own responsibility for her well-being.

The therapist’s conclusions were: patient significantly increased her capacity for self-regulation of emotions and her sense of identity became more complete.

PSYCHOSOMATIC CONNECTIONS IN PATIENT WITH GASTROINTESTINAL DISORDERS

INSTITUTIONS
1. Mental health research institute, Borderline psychiatry department, Tomsk, Russian Federation

AUTHORS
1. Alexei Konstantinovich Kostin1, Mr., MD, redo@mail.tomsknet.ru

AIM: The aim of the study was to assess the connections between psychic and somatic disorders in patients with peptic ulcer disease (PUD), irritable bowel syndrome (IBS) and their combination.

METHODS: One hundred and fifty consecutive inpatients satisfying the criteria for irritable bowel syndrome, peptic ulcer disease were participated. Subjects were classified into three groups according to gastrointestinal pathology: IBS 53 patients, PUD 57 patients, 40 patients with combination of PUD and IBS. The life stress and symptom intensity measures were determined from interview.

RESULTS: IBS, PUD severity appears to be most responsive to major life events. In 60,0% cases connected with the patient's family. In addition, vital exhaustion, which may in part result from sustained stress, may represent the psychophysiological symptom complex most closely associated with exacerbation of psychosomatic process. Patients show an enhanced responsiveness of this system manifesting in altered modulation of gastrointestinal motility and secretion and in alterations in the perception of visceral events. Lifelong patterns of response to threat was learned in the interaction between an infant and his or her primary caregiver and in 92,7% they was abnormal. Neurotic disorders were determine in 45,3%, affective (depressive) in 25,3%, personality disorders 18,7%, organic in 10,7%. The prevalence of more severe pathology was in the cohort of patients with combination of PUD and IBS.

CONCLUSION: Complex of long-term psychological stresses, family factors, personality traits, somatic diseases play a significant role in the pathogenesis of psychosomatic disorders.

BIOLOGICAL PREDISPOSITION IN TRANSSEXUAL PATIENTS

INSTITUTIONS
1. Rostov State Medical University, Psychiatry & Narcology Department, Rostov-on-Don, Russian Federation

AUTHORS
1. Alexander Ivanovich Kovalyov1, Dr., MD, aik_psych@list.ru

Objective: To reveal the biological predisposition of transsexualism.

Methods: Mainly clinical-psychopathological and genealogical. Examined was biological predisposition, which included the analysis of inherited deficiency, peculiarities of pregnancy and delivery.

Subject: 74 patients - 49 adults, 25 kids and teenagers (6 boys and 19 girls ageing between 5 and 18). The adult patients requested to change their sex. The kids were examined on their parents’ initiative due to the inversion of sex-role behavior. The selection criteria were: inversion of personality sex socialization, inversion of psycho-sexual (in both adults and teenagers) orientation, absence of any other mental illnesses and urogenital system deformities. Inherited deficiency was analyzed according to the following factors: a) mental disorders, both non-psychotic and psychotic; dipsomania; b) personality disorders, among them behavioural abnormalities (sex-role behavior abnormality, family disharmony, no marriage after 35, suicides, convictions); c) somatic pathology (II type diabetes, other endocrine diseases, cancers). Altogether we have registered mental disorders in 99.9% of the 1st degree-of-kindred relatives. As to the mental disorders, dominating was dipsomania, especially among male relative (fathers, siblings) (31%). Personality disorders were found in more than 90% of the 1st degree-of-kindred probands. Somatic pathology was found in 36.4% of the 1st degree-of-kindred probands (high occurrence of II type diabetes in mothers).

Results: The biological predisposition analysis showed possible common specific pathogenetic peculiarities in female and male transsexualism. Meanwhile, the problem demands further multidisciplinary research.

SEXUAL FUNCTION IN WOMEN WITH A HISTORY OF CHILD SEXUAL ABUSE

INSTITUTIONS
1. Psychiatric Center Rigshospitalet, Sexological Clinic, Copenhagen, Denmark
2. University of Copenhagen, Faculty of Health Sciences, Department of Neurology, Psychiatry and Sensory Sciences, Copenhagen, Denmark
3. Mental Health Services, Psychotherapy Centre Stolpegaard, Gentofte, Denmark

AUTHORS
1. Ellids Kristensen$^{1,2}$, Mrs., MD, ellids@rh.dk
2. Marianne Lau$^3$, Mrs., MD, PhD, MALA@psv1.regionh.dk

Aims/Objectives
The aim of this study was to investigate sexual function in women with a history of intrafamilial child sexual abuse (CSA), and factors influencing the sexuality.

Methods
A sample of 161 women with a history of hands-on intrafamilial CSA filled out questionnaires concerning social and psychic functioning, body image, and current sexual life in addition to a clinical interview$^1$, before starting treatment in specialist treatment groups$^2$.

Results
Sixty percent were unsatisfied with their sexual life. The women with unsatisfying body image were more unsatisfied with their sexual life. Nearly three quarter of the women were unsatisfied with their body image and two fifth did not enjoy bodily caress. Three fifth of the sexual active women describe at least one dysfunction. Nearly half of the sexual active women describe orgasmic dysfunction and nearly half describe dyspareunia. Frequency of dyspareunia and vaginismus were both correlated to not have had a supporting adult in childhood. Problems with sexuality were correlated to general wellbeing and the occurrence of flashbacks.

Conclusions
The present study showed that most of the women with a history of intrafamilial CSA starting treatment in adulthood had a sexual life with a high frequency of dysfunctions and low sexual contentment. The sexual problems may have a substantial influence on the sexuality in a relationship. The results emphasises the significance of addressing sexuality in therapy.

4. Irena Krupka-Matuszczyk$^4$, Prof.
5. Eugeniusz Kucharz$^5$, Prof.

Aim: In Systemic Lupus Erythematosus (SLE) the involvement of the central nervous system may worsen the outcome of the disease. The American College of Rheumatology (ACR) defined in 1999 criteria for 19 neuropsychiatric syndromes in SLE including cognitive dysfunction, which seems to be a relatively stable feature of the disease. The objective of this study was to evaluate cognitive deficits in patients suffering from SLE.

Methods: Eleven female patients aged 19 to 37 with SLE underwent the investigation. The Vienna Test System was applied to measure the cognitive functioning. All subjects were also diagnosed with Stait and Trait Anxiety Inventory (STAI) and Beck Depression Inventory (BDI).

Results: The scores of the BDI were 5 to 25 which excluded a comorbid depression. State and trait anxiety as measured with STAI was only mild or moderate. The analysis of the scores in the Vienna Test System showed presence of different cognitive deficits in 27 to 45 % of the patients.

Conclusion: The results show considerable deficits in attention and working memory mechanisms in examined subjects. As in the beginning of the study the influence of anxiety and depression was excluded as a potential factor affecting the results, we can assume that observed cognitive deficits in SLE are functional and not reactive.

Previous studies have shown associations between size at birth and both cardiovascular and psychiatric disorders, but the role of prenatal growth specifically on the development of personality disorders remains unclear. We studied the associations between size at birth and personality disorders in adulthood among 6506 Finnish men and 5857 women born between 1934 and 1944. Size at birth was extracted from birth records and diagnosis of personality disorders from the national Finnish Hospital Discharge Register where diagnosis has been entered from 1969 onwards for each hospital stay. 103 men and 80 women (total 1.5% of the sample) had been treated in hospital with the diagnosis of a personality disorder. After adjusting for gestational age, childhood socioeconomic status, sex, and year of birth, head circumference at birth showed a curvilinear (an inverse J-shaped) association with personality disorders (p=0.006). Subjects with a small head circumference (<-1 standard deviation (SD) score) at birth had a 1.62 fold (95 % CI, 1.10 to 2.39, p=0.01) higher risk for personality disorders in adulthood than those with an average head circumference (-1 SD to 1 SD). This effect was significant among men only (p=0.04). Moreover, in men, a smaller head to length-ratio at birth predicted linearly personality disorders (p=0.02). No significant associations were found for gestational age, weight, length, or ponderal index at birth and personality disorders. The results emphasize the importance of prenatal programming of brain growth in the development of personality disorders.

Objective: To evaluate treatment effectiveness of risperidone long-acting injection (RLAI) in recently diagnosed schizophrenia patients versus those diagnosed for a longer period.

Methods: The electronic-Schizophrenia Treatment Adherence Registry (e-STAR) is an international, prospective, observational study of patients with schizophrenia who start RLAI. Data are collected retrospectively (1-year) and prospectively every 3 months (2 years). Effectiveness was measured by the Clinical Global Impression-Severity (CGI-S) and the Global Assessment of Functioning (GAF) scale. Recency of diagnosis was dichotomized into those diagnosed recently (<5 years) versus patients who have been diagnosed longer (≥5 years). This interim report is based on pooled data from Australia, Belgium, Czech Republic, Denmark, Netherlands, Slovakia, Spain, and Sweden.

Results: Among 4,252 patients enrolled in e-STAR, to date, 2,239 patients have been followed for at least 12 months with 44% of them classified as recently diagnosed. Compared to recently diagnosed patients, those diagnosed longer were older (42.5 vs. 31.4 years, p<0.001) and had longer disease duration (16.2 vs. 2.2 years, p<0.001). The proportion of patients still on RLAI at 12 months was similar in both groups (diagnosed <5 years=85.2%, diagnosed ≥5 years=85.6%). Both groups experienced significant improvements in CGI-S and GAF scores. However, the recently diagnosis group experienced greater improvements in CGI-S and GAF (CGI-S, -1.28 vs. -0.99, p<0.0001; GAF, +17.1 vs. +14.1, p=0.0002).

Conclusions: This 12-month interim outcome data show that RLAI treatment significantly improves illness severity and patient functioning in patients with schizophrenia, those who were recently diagnosed experienced greater improvement compared to those diagnosed longer.

AND SUBJECTIVE DEPRESSION, SLEEPINESS AND SLEEP QUALITY AND THEIR CORRELATIONS IN DIFFERENT SLEEP DISORDERS: WHAT DOES BDI IN SLEEP APNEA MEASURE?

INSTITUTIONS
1. Max Planck Institute of Psychiatry, Germany
2. 1st Faculty of Medicine, Charles University, Department of Psychiatry, Czech Republic

AUTHORS
1. Zuzana Lattova\textsuperscript{1,2}, MD
2. Marietta Keckeis\textsuperscript{1}, Mag. nat.
3. Thomas Pollmächer\textsuperscript{1}, Prof., MD

Objectives: Daytime sleepiness and disturbed sleep quality are the core symptoms of sleep disorders. Depressive symptoms are often reported to be associated with sleep disorders. We examined the relationship of daytime sleepiness, sleep quality and depressive symptoms in three different patient groups: Obstructive Sleep Apnea (OSA), Restless Legs Syndrome (RLS) and Psychophysiological Insomnia (INS).

Method: Physically healthy subjects without history of psychiatric diagnosis and psychotropic medication use were included. ESS for daytime sleepiness assessment and PSQI for the subjective sleep quality were administrated. Participants filled in BDI as indicator of subjective depression and underwent a standard psychiatric interview, finally HAMD and HAMA were filled in.

Results: ESS scores were significantly higher in OSA compared to INS. PSQI and HAMA scores were significantly higher in INS. HAMD scores were significantly higher in the INS compared to OSA. Interestingly, the BDI score did not differ significantly between the groups. HAMD and BDI scores correlated significantly in INS and RLS, but not in OSA patients. There were interesting correlations in the OSA group. BDI correlated with objective sleep parameters (AHI, ODI) as well as with subjective sleep quality (PSQI) but not with objective psychiatric scales. On the other hand, HAMD and HAMA correlated with ESS.

Conclusion: Symptoms of daytime sleepiness, sleep quality and objective symptoms of depression differ significantly among the groups. However, subjective symptoms of depression do not differ significantly. It seems that in OSA group the scores ESS and BDI interfere with some more factors than daytime sleepiness and depression.

DOMESTIC VIOLENCE AND RELATIONSHIP TO ALCOHOL USE AT AN EMERGENCY DEPARTMENT IN EASTERN TAIWAN

INSTITUTIONS
1. Tzu Chi Buddhist General Hospital, Tzu Chi University, Family Medicine, Public Health, Hualien, Taiwan Republic of China

AUTHORS
1. Yin-Ming Li\textsuperscript{1}, yinming@mail.tcu.edu.tw

Objectives: Domestic violence (DV) threatens the health and safety of family members, and alcohol involvement may play a role in the violence. This study investigated the characteristics of DV patients and their association with alcohol drinking.

Materials and Methods: Patients admitted to the emergency department (ED) because of an injury that was the result of violence (being in a fight or being attacked by someone at home) were included in this study. Injuries were defined as alcohol-associated based on the report of "alcohol odor" or "intoxicated" by the nurse. Medical records of DV injuries were reviewed for confirmation of DV, record of the offender and any known mental disorder. Logistic regression was used to assess the significant factors related to alcohol-associated violent injuries.

Results: Of 11,837 trauma visits, 142 patients had DV injuries. Females accounted for 67.6% of injured patients and 59.2% were aged 24-44 years. Of the 142 patients, 37.3% of them had alcohol-associated injuries. The percentage of alcohol-associated DV injuries was 50.0% for males and 31.3% for females. Multiple logistic regression analysis found that being male, being aged 25 to 44 years, visiting after midnight, presenting at the ED between 4 pm and midnight or on a week day meant a significant increase in the likelihood of alcohol involvement.

Conclusions: Alcohol use was found to be present in one-third in the DV injuries from an ED in eastern Taiwan. Ongoing epidemiological investigations of the causal relationship between alcohol use and DV are urgently needed.

“TRAINING ATHLETE” SYNDROME AND DEPRESSION IN TRANSCULTURAL CONTEXT

INSTITUTIONS
1. SFU, Austria
2. Health Associates, United States

AUTHORS
1. Zhu Li Jing1, Dr., zhulijing@gmx.net
2. John Heil2, Dr.

“Training athlete” is a frequent problem in daily sport training, which leads to achievement stagnation, and the athlete becomes a “difficult, problem” athlete in the team. There is no direct method to solve this “Training athlete” problem. The coaches claim, “On a white paper is much easier to paint a picture than on a ready painted paper” - it is better to train a new athlete.

This study delineates an empirical qualitative study in which seven Chinese competitive athletes showing achievement problems (selected by key informants: three male, four female) participated in qualitative narrative interviews. An initial evaluation was made through content analysis utilizing the model of Mayring, and subsequent analysis by DSM-IV diagnostic criteria, and parallel TCM diagnostic criteria. The evaluation through qualitative content revealed nine main categories containing: depressed mood; excessive worry; somatic complaints; irritability; sleep problems; excessive dieting, menstrual irregularity, weight gain; excessive alcohol intake and to accept doping under condition; physical injury; as well as social and communication problems and restricted contact between the genders. Two cases were “training athlete”, Case two fulfilled Major depressive episode (MDE) in DSM-IV; case seven the criteria of Dysthymic Disorder (DD) in DSM-IV. Case two met criteria for Zang Zao - Heart Kidney Deficiency - Depression (HKDD), case seven for Heart Spleen Deficiency - Depression (HSDD) and Amenorrhoea (A) in TCM. An awareness of “training athlete” syndrome and associated depression in athletes is necessary for the sake of the athletes.

The psychogeriatric population which usually presents with a combination of psychiatric acute pathology and somatic pluripathology, has a tendency to polypharmacy, severe fragility and clinical complexity.

OBJECTIVE: to describe the comorbidity and the psychopharmacological treatment of the geropsychiatric patient in a specific Unit

METHODS: A descriptive cross-sectional retrospective analysis was carried out based on the outcome data in a period of 7 months in the Geriatrics Psychiatry Unit of the Sagrat Cor Hospital in Martorell

RESULTS: 72.6% of admitted patients were women with a median age of 72.7 + 6.3. In our unit, affective disorders are the most frequently diagnosed psychiatric conditions, followed by dementia, personality disorders and schizophrenia. On the other hand, the most frequently diagnosed medical conditions are cardiovascular risk factors followed by pathology of the bones. The average drug consumption at discharge was 6.9 . Of this, 3.3 were attributed to medical treatments with special emphasis on gastric protection, painkillers, antihypertensive medications, protein supplements and laxatives. The other 3.6 was attributed to psychiatric medication.

CONCLUSIONS: Although the most frequent diagnosis were affective disorders the antipsychotic drugs were highly used. The multidisciplinary care in our unit is reflected at discharge where we emphasize a good balance between psychiatric and organic conditions. Diagnosis and treatment of vascular risk factors, geriatric syndromes (pain, malnourishment, constipation) and social problems are essential elements in the treatment and stabilization of psychiatric pathology and/or dementia syndromes.

Aims: To create a personality model that could distinguish pathological gambling (PG) subjects from their non-PG siblings; to verify whether this model would be useful in an independent population-based sample of PG.

Methods: Temperament and Character Inventory (TCI) was used to assess personality features on 140 sib-pairs discordant for the diagnosis of PG in Brazil (treatment seeking PG subjects). A logistic regression model was developed, and was subsequently applied to a population-based sample of 214 PG subjects and 116 controls in Canada. No data regarding psychiatric comorbidity, gender or age were added to the regression in order to obtain a general personality model.

Results: TCI’s subscales novelty seeking 3 (extravagance), reward dependence 3 (social detachment), self-directedness 1 (blaming of others), self-directedness 2 (goal-undirected actions), and self-directedness 5 (self incongruence) were able to correctly classify 89.3% of the overall Brazilian sample (sensitivity 95.7%, specificity 83%) and 76% of the Canadian sample (sensitivity 73%, specificity 80%). Novelty seeking 3 had the higher effect in both models (OR=2.14 - Brazilian sample, OR=1.5 - Canadian sample).

Conclusions: The model held good overall prediction in two very distinct samples. These results suggest that this model might be useful in identifying PG subjects, and this should be further investigated in future studies. Also, the results underline the importance of addressing personality characteristics that could influence treatment, such as high impulsivity and decreased ability to achieve goals. Our study is limited by its cross-sectional design.

5. Neophytos Theodorides
6. George Garyfallos
7. Aravella Adamopoulou

Aims/Objectives: Clinical experience suggests that a high percentage of patients with borderline personality disorder meet criteria for axis I disorders during the course of outpatient treatment or when hospitalized for psychiatric reasons. Many studies demonstrated that mood disorders, particularly unipolar disorders, are common.

Methods: A clinical sample of 109 outpatients, 84 females and 25 males, who, according to DSM-IV-TR, suffered from Borderline Personality Disorder and have been treated at the Community Mental Health Centre between 2005 and 2006, were examined.

Results: A significantly higher percentage of borderline patients were women. The proportion between women and men was almost 3:1. Most of the patients have multiple diagnoses. 19(76%) males and 72(85,7%) females comorbid one or more axis I disorders. 60,6% of our patients suffered from mood disorder: 10(40%) males and 56(66,7%) females, with tendency for depression mostly for females (52,4 vs 36%). Summing up both sexes, 48,6% of our patients suffered from depression, 5,5% from bipolar disorder, 5,5% from dysthymic disorder and 1,8% from cyclothymic disorder.

Conclusions: These results support previous findings of high rates of comorbidity of borderline patients. In addition, suggest that there is a significant association between borderline personality disorder and mood disorders. Female borderlines were significantly more likely than male borderlines to meet DSM IV-TR criteria for mood disorders. These results suggest that gender plays an important role in the expression of Axis I and comorbidity of BPD patients.

Somatoform and dissociative disorders are characterized by somatic symptoms caused by psychological factors lacking organic base. The crucial diagnostic task is to exclude potential somatic disorder. Previous studies show that 25 to 50% of patients with conversion symptoms were later diagnosed with somatic disorder. The course of differential diagnosis may lead to the possibility of somatic and psychiatric comorbidity. This case report illustrates a patient with overlapping dissociative (pseudo-neurological) disorder and actual neurological disorder. Due to clinical feature of a hemiplegia without pyramidal lesion gradual oligosymptomatic development of Parkinson’s disease was overlooked. The appearance of obvious clinical features of Parkinson’s disease was precipitated after administration of a low dose antipsychotic (risperidone). Increasing hemi-hypertonia was then followed by typical tremor continuing to exist after discontinuation of antipsychotic medication. The utmost importance of thorough diagnostic procedure and close collaboration between psychiatrist, neurologist and psychologist is emphasized.

6. Jasmina Jankovic, Dr, MD

Counseling service for sexual and gender identity disorders is organized as an out-patient functional unit of the department of psychiatry within the clinical and hospital center “Dr Dragisa Misovic”. It is the only service of this kind in a state general hospital in Serbia. Unit staff is currently consisted of two psychiatrists specialized in sexology and marital therapy, resident psychiatrist, psychologist and relaxation therapist. The service is engaged in multiple activities:
- Diagnostic assessment of sexual dysfunctions and gender identity disorders;
- Treatment of sexual dysfunctions sometimes on an integrative basis (sexual therapy, pharmacotherapy, marital counseling, relaxation and EMDR therapy);
- Psychiatric and psychotherapeutic management of gender identity disorders, indication and preparation for hormonal and surgical treatment;
- Consulting service for other departments (urology, gynecology, endocrinology…) and psychiatric units;
- Interactive educational activities through day hospital patient clubs;
- Research activities within the department and multidisciplinary research projects on the Institute of cardiology and department of gynecological endocrinology of the University clinical center;
- On-line communication with general population through our clinical center site and virtual youth counseling service.

KLEPTOMANIA AND BIPOLAR SPECTRUM DISORDERS

INSTITUTIONS
1. Nossa Sra do Rosário Hospital, Psychiatry and Mental Health Department, Barreiro, Portugal

AUTHORS
1. Susana H. Mendes, Dr., MD, susanahmendes@gmail.com
2. Susana Fernandes, Dr., MD, susanafernandes@netcabo.pt
3. Guida Ponte
4. Zaida Pires, Dr., MD, zpires@netcabo.pt
5. Margarida Lobo, Dr., MD, lobomargarida@yahoo.com

Kleptomania, is defined by DSM-IV as the inability to resist the impulse to steal objects which are not needed for personal use or for their monetary value. It may reflect a form of obsessive-compulsive spectrum disorder, has originally conceptualized, but new evidence (clinical characteristics, familial transmission, and treatment response) suggests that kleptomania has important similarities to bipolar spectrum disorders and addictive disorders. Elevated rates of mood disorders also co-occur in kleptomania.

We present a case of a 46 years old woman with history of kleptomania since she was 20 years old, but never recognised or treated. 6 years ago, she had her first mania episode, and began treatment for bipolar disorder with complete remission of kleptomania. Kleptomania tended to emerge again, whenever she had a depressive episode. It is important to study the relationship between kleptomania and other major psychiatry disorders, in order to provide the correct pharmacological treatment and behavioural intervention.

THE QUALITY OF LIFE AND DEPRESSION AFTER ACUTE INFECTIONS OF THE CENTRAL NERVOUS SYSTEM

INSTITUTIONS
1. Zvezdara University Medical Center, Daily psychiatric hospital, Belgrade, Serbia and Montenegro

AUTHORS
1. Aleksandar M Miljatovic, DR, MD, aleksandarmiljatovic@yahoo.com

Objective: The effects of acute infections of the CNS can be complete recovery or partial recovery with consequences. The aim of this study is to establish differences in the assessment of the components of life quality in relation to the outcome of the illness, separately for each of the three groups of the examinees (CR - completely recovered, RC -recovered with consequences and C - control group). We also wanted to point out the differences in the level of depression between these 3 groups.

Methods: The study includes 100 examinees that were treated at the Clinic for Infectious Diseases in Belgrade. "Medical Outcomes Study Short Form 36 questionnaire" and "Hamilton Depression Rating Scale (17 items) were used as a measuring instruments.

Results: In the RC group, 35% had no emotional problems, 74% preserved social functioning skills and 55% felt tranquil and happy. There is a significant degree of differences in the level of depression between the examinees of these three groups.

Conclusion: The analysis of the differences between groups in relation to the assessment of mental components showed that there is a moderate distance between the control group and the group of completely recovered. It also showed that the biggest difference is between the group of completely recovered examinees and those who recovered but with consequences. High level of depression on Hamilton Scale demands a treatment with antidepressants for those examinees belonging to the RC group.

DISORDERED SLEEP AND SLEEP-RELATED DAYTIME FUNCTIONING IN FIBROMYALGIA SYNDROME (FMS)

INSTITUTIONS
1. Centre for Sleep & Chronobiology, Sleep Disorders Clinic, Toronto, Ont., Canada
2. Jazz Pharmaceuticals Inc., Biostatistics, Palo Alto, CA, United States

AUTHORS
1. Harvey Moldofsky, Dr., MD
2. Sarah Alvarez-Horine, PhD

Objective: To assess the incidence of sleep-related problems in disordered sleep and daytime functioning in a US multicenter study of subjects with Fibromyalgia Syndrome (FMS).

Methods: In 304 subjects [95.4% female, mean +/-SD age 47.6 +/- 11.6 yrs, BMI 30.7 +/- 7.4, mean duration of illness 11.1 +/- 9.8 yrs], we evaluated subjective ratings of sleep and daytime function: sleep quality (depth, refreshing/unrefreshing sleep VAS), sleep quantity, sleep impairment (Jenkins Scale [JS 0-20]), daytime sleepiness (morning VAS, Epworth Sleepiness Scale [ESS 0-24]), and disturbances of daytime functioning (Functional Outcome of Sleep Questionnaire [FOSQ 5-20], Vitality domain [SF-36 0-100]). Sleep physiology and anomalies, objectively determined by polysomnography (PSG), were evaluated in a subgroup of 209 subjects.

Observations: Sleep Quality: 78.9% light sleep; 90.3% unrefreshing sleep; 85.6% morning sleepiness; JS=15.6 +/- 4.0; ESS=10.3 +/- 5.3; FOSQ=12.3 +/- 3.4; Vitality=30.3 +/- 6.8.

Sleep Quantity: 59.6% delay in sleep onset; 65.8% 3 or more awakenings; 42.3% >= 1 hr wake time during sleep, 73.7% sleep < 6 hrs; chronicity >= 5 mo. 97.6%. PSG Analyses: Sleep Onset Latency: 28.4 +/- 28.8 min; Total Sleep Time 362.1 +/- 79.7 min.; Sleep Efficiency= 76.6% +/- 16.4; Arousal/hr. of sleep =18.2 +/- 12.7; Alpha EEG sleep moderate to severe (> 40% NREM sleep)=66.0%. Elevation of the cyclical alternating pattern rate (n=93) = 60.5% +/- 21.6.

Apneas and hypopneas/hr of sleep: mild (5 < 15)=27.8%; moderate (15 < 30)=10.5%; severe (30+)=4.8%.

Periodic limb movements/hr of sleep: mild (5 < 15)=15.3%; moderate (15 < 30)=4.3%; severe (30+)=0.5%.

Conclusions: This is the first report in a large cohort of FMS subjects documenting the high incidence of subjective and objective sleep pathology associated with impaired daytime functioning. Improving these symptoms in FMS patients remains an important unmet medical need.

THE PSYCHIATRIST IN AN INFECTIOUS DISEASE UNIT A SIX MONTH EXPERIENCE

INSTITUTIONS
1. Hospital de São João, Psychiatry, Porto, Portugal

AUTHORS
1. Patricia Nunes, Dr., patricialopesnunes@gmail.com
2. João Marques, Dr.
3. Miguel Bragança, Dr.
4. Marcia Mota, Dr., marciamota@netcabo.pt

Infectious Disease inpatient population reveals a high psychiatric comorbidity, mainly patients with HIV/AIDS. In fact, the interrelation between immunodeficiency virus (HIV) infection and mental illness is a complex one, with HIV infection adding stress to the already compromised coping skills of the mentally ill, while mental illness itself may increase risk behaviors and thus predispose the affected person to HIV infection.

Objective: Characterize the liaison psychiatry consultation in the São João Hospital infectious disease unit and in particular to characterize the HIV/AIDS inpatient profile and psychiatric comorbidity.

Method: The authors designed a specific protocol to obtain data on all patients referred to the infectious diseases Psychiatric Liaison Unit between January and June 2008, with the following items: sociodemographic data, hospitalization and referral motive, psychiatric diagnosis, accuracy of the initial referring psychiatric diagnoses, previous psychiatric disease and psychopharmacologic medication, way of contagion, antiretroviral medication compliance, risk behaviors and disease stage (for HIV patients).

Preliminary results: The ongoing study reveals that most of the referred cases are male HIV/AIDS patients with history of substance abuse that are hospitalized for complications of the primary disease. The main reasons for referral are evaluating coping problems, depressive symptoms, behavioral disorders due to substance abuse, and assessment of psychotropic medication. The most common psychiatric diagnoses are mood disorders, psychoactive substance use disorders and organic mental disorders. So far, these preliminary results are in agreement with other researches in literature.

Discussion: The results will be discussed upon the most recent research in this area.

OPINIONS ON DUAL DIAGNOSIS IN MENTAL ILLNESS AMONG MULTI-PROFESSIONAL STAFF

INSTITUTIONS
1. Abarbanel Mental Health Center, affiliated with the Sackler School of Medicine, Tel Aviv University, IDDTW, Bat Yam, Israel

AUTHORS
1. Yuri Gimelfarb, ystatist@gmail.com
2. Sabry Elwahidi
3. Zipti Natan

BACKGROUND: The rate of dual diagnosis patients (suffering from both mental illness and addiction)-DDP is constantly increasing. In order to improve the service the Integrated Dual Diagnosis Treatment Ward was founded in our centre, but some of the DDP are hospitalized in other wards. The science evidence on multi-disciplinary staff members’ opinions on the DDP has not been found yet.

OBJECTIVE: To compare the multi-staff members’ opinions on mentally ill patients to these on the DDP.

METHODS: The sample population comprised 44 subjects (20 males (45.5%), mean age 42.1 years (SD=8.2), mean education 16.8 years (SD=3.0)).

Tools: The questionnaire “Opinions on Mental Illness” with dimensions: Authoritarianism, Social restrictiveness, Interpersonal etiology, Mental hygiene, Dangerousness (Cohen & Struening, 1962). The questionnaire “Opinions on Dual Diagnosis Illness” with the same dimensions (Alpha (Cronbach)=.8).

RESULTS: The mean score of the Interpersonal etiology among the nurses toward the mentally ill patients was 0.2 higher than toward the DDP, and 0.5 lower among the other staff members (p<.01). The mean score of the Mental hygiene among the nurses toward the mentally ill patients was 0.4 lower than toward the DDP, and 0.4 higher among the other staff members (p<.01). The mean score of the Dangerousness among the nurses toward the mentally ill patients was 0.2 lower than toward the DDP, and 0.8 higher among the other staff members (p<.007).

CONCLUSIONS: Nurses avoid from contacts with DDP. Advanced training for multi-staff members is required to give a proper response to DDP’s unique needs.

EFFECTIVENESS OF ARIPIPRAZOLE (AN NEW ANTIPSYCHOTIC) IN CONTROL OF DIMENSION IMPULSIVENESS-HOSTILITY IN PERSONALITY DISORDERS CLUSTER B

INSTITUTIONS
1. Hospital of Motril, Dept. of Psychiatry, Motril (Granada), Spain
2. Provincial Hospital of Almeria, Dept. of Psychiatry, Almeria, Spain

AUTHORS
1. Juan Carlos Navarro-Barrios¹, Dr., MD, PhD, andere21@hotmail.com
2. Inmaculada Esteban-Pinos¹, Dr., MD
3. Maria Luisa Gonzalez-Montoro¹
4. Dolores Carretero¹
5. Anselmo Canabate-Prados²

Personality disorders (PD) are defined by the APA as "an enduring pattern of inner experience and behavior that deviates markedly from the expectations of the culture of the individual who exhibits it". PD type Cluster B are: Antisocial, Borderline, Histrionic and Narcissistic personality disorder. The dimension Impulsiveness - Hostility is a frequent motive of consultation in the patients with PD.

AIMS: To evaluate the effectiveness of Aripiprazole in the control of the impulsiveness in Personality Disorders Cluster B.

METHODS: Aripiprazole was used as pharmacological treatment in 12 subjects, with diagnosis of Borderline PD (n=8), Antisocial PD (n=2), and Histrionic PD (n=2), with ages between 18 and 59 years, associated with bosses of acting-out. The average dose of the Aripiprazole was of 15 mg/day. in some moment of the treatment 75% of the patients received benzodiazepines, and 41.6% received an SSRI. We not utilized other antipsychotic or other anti-epileptic. The instrument utilized for to evaluate the impulsiveness was Barratt's scale at the beginning and to 20 weeks of treatment. For this study we valued as improvement for the control of the symptoms the reduction of 20% of the total punctuation of the subscales, to 20 weeks of treatment, with relation to the basal.

RESULTS: We founded improvement in Barratt's scale at the week 20 of treatment, in 58.3% of the subjects (n=7). The subscale with more improvement was the Motorboat subscale.

CONCLUSION: Aripiprazole can be useful for control of the acting-out in the Personality Disorders, needing open study and double-blind.

FUNCTIONAL GASTROINTESTINAL DISORDERS AND PSYCHOPATHOLOGY: TOWARD A NEW DIMENSIONAL APPROACH

INSTITUTIONS
1. University of Pisa, Psychiatry, Pisa, Italy
2. Clinic of Psychiatry, Livorno, Italy
3. University of Pisa, Gastroenterology, Pisa, Italy

AUTHORS
1. Cristiana Nisita¹, Mrs., MD
2. Giorgio Corretti², Mr., MD, gcorretti@yahoo.it
3. Sonia Cortopassi¹, Mrs., MD
4. Massimo Bellini³, Mr., MD

Introduction: Functional Gastrointestinal Disorders (FGD) are a common reason to consult a physician (GP or specialist). Sometimes, the absence of organic sign ascribes to these patients labels such as: neuroticism, stress, and aspecific psychological factors. Categorical disorders can describe only a part of psychopathology in FGD. Sub-threshold symptomatology can better describe this phenomenon.

Aim of our study was to assess sub-threshold symptomatology in FGD population and to determine how these symptomatology interfere with the well-being.

Material and Method: 130 FGD's patients was studied. Axis I Disorders was evaluate with SCID-IV, sub-threshold symptomatology with: Mood Spectrum (SCID-MOODS-sr), Panic (SCID-PAS-sr), Obsessive Compulsive (SCID-OBS-sr), Social phobic (SCID-SHY-sr) ed Bulimic-Anorectic (SCID-ABS-sr). Gastrointestinal symptomatology and well-being was assessed with specific questionnaires (Rome II Criteria).

RESULTS: Almost half of patients had one Axis I Disorder (Panic 26.8%, Generalized Anxiety 20.2% Moods Disorder 15.0%). A spectrum diagnosis was found in 27.5% of patients without an Axis I diagnosis. Panic disorder and panic spectrum such as mood disorders and mood spectrum showed a similar prevalence. Obsessive compulsive and social phobic spectra are widely more represented than related categorical diagnosis. Obsessive compulsive and social phobic spectrum was significantly correlated to a lower well-being (p<0.01).

Conclusions: A spectrum diagnosis better defines FGD condition. A spectrum diagnosis - obsessive or social phobic - characterizes FGD's wellbeing. A new essential step was represented by the assessment of spectrum diagnosis and global level of well-being independently from Axis I disorders. This new approach may be extended to other medical population.

BULIMIA NERVOSA IN A 57 YEAR OLD MALE NIGERIAN CHIEF MAGISTRATE: CASE REPORT

INSTITUTIONS
1. University of Calabar, Department of Psychiatry, College of Medical Sciences, Calabar, Nigeria
2. University of Calabar, Department of Internal Medicine, College of Medical Sciences, Calabar, Nigeria

AUTHORS
1. Emmanuel C. Okereke¹, DR, MD, dremaokereke@yahoo.com
2. Regina E. Agbulu², DR, MD

Introduction: Bulimia means binge eating; eating more food than most persons, accompanied with a strong sense of losing control. The text revision of the fourth edition of Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR), defined bulimia as binge eating combined with inappropriate ways of stopping weight gain.

Aims: To present and discuss the peculiarities of this uncommon presentation of Bulimia Nervosa.

Method: Case report The patient is a 57 year old retired male Nigerian chief magistrate. He was referred by the family medicine clinic of the university teaching hospital to internal medicine department for treatment of vomiting after meals of 10 months duration. Extensive assessment and investigations by the consultant physician revealed no abnormality and a diagnosis of psychogenic vomiting was made. The patient was then referred to the consultant psychiatrist in the teaching hospital. History and thorough assessments by the psychiatrist revealed that the patient had induced vomiting at least twice daily after the habit of overfeeding himself for a duration of over 30 years. He claimed he induced the vomiting because he felt bloated and disgusted after overfeeding himself. He only sought for medical help when the situation was “out of control” as he induced vomiting more than four times daily.

Conclusion: This case is not in keeping with similar cases in its presentation especially as it relates to the gender. The challenges of this case are discussed and the management protocol instituted yielded positive results.

SOMATIC MORBIDITY AND HEALTH CARE CONSUMPTION IS ASSOCIATED WITH PERSONALITY DISORDER

INSTITUTIONS
1. Innlandet Hospital Trust, Department of Psychiatry, Hamar, Norway
2. The Norwegian Radium Hospital, Department of Clinical Cancer Research, Oslo, Norway

AUTHORS
1. Ingrid Olsson¹, Dr., PhD, ingrid.olsson@sykehuset-innlandet.no
2. Alv A Dahl², Dr., PhD

Aims/Objectives Associations between somatic morbidity, somatic symptoms, health care consumption and neuroticism as a basic personality trait have been demonstrated. Since little is know concerning associations between these factors and personality disorders, the aim of this study was to explore such associations in a population-based sample.

Methods: The Oslo Health study invited all the 26,113 citizens of Oslo aged 30, 40, and 45 years to a health survey, and 10,436 (40%) responded and filled in questionnaires. Among them 8,440 (81%) filled in The Iowa Personality Disorder Screen (IOWA). Persons over case level of anxiety/depression (SCL-10) were omitted, and 369 individuals who filled the criteria for personality disorders (PDs-group) were compared to 5 age and gender matched controls (N=1,845) without any signs PDs (non-PDs group).

Results: The PDs group showed significantly poorer self-rated health and had more alcohol problems, fibromyalgia and chronic musculoskeletal pains compared to the non-PDs group. Members of the PDs group used significantly more non-prescribed analgesics, and they more frequently visited GPs and non-psychiatric specialists. They also significantly more often saw psychiatrists/psychologists and used more of any kind of psychotropic medication. In addition, the PDs group was less satisfied with their last GP visit. All these differences were also significant in multivariate analyses.

Conclusion: In this population-based, cross-sectional study of young adults we observed that individuals with PDs with low levels of anxiety/depression had poorer somatic health, used more psychotropic and analgesic medication, and visited GPs and psychiatric professionals more frequently than individuals without PDs.

RELATIONSHIP OF SELF ESTEEM AND PSYCHIATRIC SYMPTOMS IN PERITONEAL DIALYSIS PATIENTS

INSTITUTIONS
1. Ankara Diskapi Residency Training Hospital, Department of Psychiatry, Turkey
2. Siirt General Hospital, Department of Psychiatry, Turkey
3. Etlik Ohtisas Hospital, Department of Nephrology, Turkey

AUTHORS
1. Hasan Karadag¹, Dr, MD
2. Akfer Karaoglan Kahıllogulları², Dr, MD
3. Ayseğul Oztemel³, Dr, MD
4. Sibel Orsel¹, Dr, MD
5. Hakan Turkcapar¹, Dr, MD

Objective:
Psychiatric disorders are common in patients with renal disease. The overlap between symptoms of chronic medical illness and those of psychiatric disorders make for a particularly challenging diagnosis in this illness. Mental disorders may effect the prognosis of disease and quality of life of the patients with renal failure (Kimmel 98). But the relationship between self esteem and psychiatric symptoms have not been determined in patients with renal failure. The aim of this study is to examine the relation of psychiatric symptoms and self esteem in peritoneal dialysis patients.

Method:
96 peritoneal dialysis patients are recruited. All of the patients gave informed consent. The symptomatology of illness is evaluated by SCL-90 and self esteem is evaluated by Rosenberg self-esteem scale.

Results:
The study population consisted of adolescents and adults aged 17-73 years with a mean age of 39.9 (SD: 13.1). Group included 54 male patients (56.3% of population) and 42 female patients (43.8% of population). Mean duration of peritoneal dialysis was 36.19 months (SD: 26.9). Significant correlations were found between all psychiatric symptom groups and self esteem.

Conclusion:
Self esteem reported to be related with illness intrusiveness in renal failure (Ozcurumez 2003); more emphasis must be placed on the role of psychiatric comorbidity on this in further studies.

DOMESTIC VIOLENCE IN COUPLES AND FAMILIES, OR DESTRUCTIVE MANIPULATION - PAGNARD G. *

INSTITUTIONS
1. Psychiatric praxis and clinic (MGEN), 92100, Boulogne, France

AUTHORS
1. Geneviève Pagnard¹, Psychiatre, dr.pagnard@gmail.com

This very destructive and insidious form of psychological violence concerns an important portion of the population (25 to 30% of women, according to Canadian and Spanish studies, without taking in the count men and children). Stemming from patients observation, the process develops in five stages, including ceaseless humiliating remarks, reproaches and insults, growing more and more violent with time. The destructive manipulator is a double-faced character, harmless outwardly, despotic and erratic in his behaviour within the family closed-door. In his quest for absolute control, he can use physical violence, rape, incest, and genuine financial abuse. The victim may develop an anxious-depressive syndrome, suicidal tendencies, alcoholism or psychosomatic disorders (such as cancer in most extreme cases), delirious de-compensation, PTSD with dissociation, etc. The children are always caught in this destructive process, which extends to divorce proceedings and visitation rights.

The manipulator succeeds to abuse the magistrates, by playing the victim while drowning his/her victim under a flood of lies and calumnies. He unleashes a costly procedural fury. On a nosological point of view, the pathology of the destructive manipulator constitutes an entity, by his symptoms at the crossroads of several pathologies, mostly related to psychosis (narcissist perversion, paranoia, psychopathic personality etc). In view of the importance of the population (male as female), victim of this destructive process, and, of the seriousness of the pathology presented by these numerous manipulators, this perverse pattern is becoming one of the priorities of public authorities in developed countries, and of magistrates in family affairs.

THE PRODROMAL PERIOD AND DUP - CLINICAL AND PROGNOSTIC VALUE

INSTITUTIONS
1. MENTAL HEALTH CENTER, DAY CLINIC, TIMISOARA, Romania
2. PSYCHIATRIC CLINIC, PSYCHIATRY, TIMISOARA, Romania

AUTHORS
1. Stoica Ileana Pepita1, Mrs /Dr, MD, pepita17stoica@yahoo.com
2. Ianciu Monica2, Mrs/ Dr, MD, pepita17stoica@yahoo.com+

The aim of the study
This study is a continuation of a tradition in Timisoara’s research project for endogenous psychosis, and we proposed to find out the clinical and prognostic value of the prodromal phase and DUP in FEP.

Material and method
The study is part of a larger follow-up research which include a number of 80 patients with a diagnosis of first episode psychosis, hospitalized in the Timisoara Psychiatric Clinic and the Timisoara Mental Health Center Day - Care unit, during the years 2003-2005. The patients were monitored from the moment of their first contact with psychiatric services up to now. For each patient have been assessed, apart from the clinical parameters:

- The duration of prodromal phase
- The duration of untreated psychosis (DUP)

Results
The duration of the prodrome influences the improvement of illness following treatment; The duration of prodrome is directly correlated with the number of relapses; DUP is directly correlated with the CGI severity score at the final assessment.

Conclusion
- Assessing the prodromal period and DUP for FEP patients is relevant for their evolution and prognosis.

Key words: first episode psychosis, prodrom, duration of untreated psychosis, evolution, prognostic value.

P-02-125
NONVALIDITY OF THE VALIDATION SCALES

INSTITUTIONS
1. Institute of Mental Health, Serbia and Montenegro
2. School of Medicine University of Belgrade, Serbia and Montenegro
3. Department of Psychology, University of Belgrade, Serbia and Montenegro

AUTHORS
1. Ivana Perunicic1
2. Dejan Florikic1
3. Dusica Lecic Tosevski1,2
4. Goran Knezevic3

Objective: In this research we try to confirm one of the basic hypotheses in psychological assessment which is that with using the validation scales subjects can be seen as giving the social acceptable answers.

Method: The sample consisted of 80 subjects (40 non-psychotic patients and 40 graduate high school students) to whom the Amoral -15 scale measuring antisocial tendencies was administered in two different situations - with the standard instruction (E1) and with the instruction to fake the responses (E2). The difference between E1 and E2 was taken as a measure of the ability to fake well. We correlated differential score (E1-E2) with the validation scales (the mix of Marlow-Crown and Eysenck’s L scale from the EPQ).

Results: Results indicated no significant correlation between the ability to fake good and the scores on validation scales. In some items we found negative correlation which means that subjects who better present themselves in social desirable way have lower scores on the validation scales.

Conclusions: Validation scales seem not to be good instruments for detecting tendencies to give social acceptable answers and therefore future research is necessary, because according to these scales subjects are often disqualified as being dishonest and we cannot be certain what validation scales are actually measuring.

PSYCHIATRY MORBIDITY WITH FOREIGN JOB AS STRESSOR

INSTITUTIONS
1. B.P.Koirala Institute of Health Sciences, Psychiatry, Dharan-18, Nepal

AUTHORS
1. Shyangwa Mohan Pramod1, Dr., MD, shyangwa@yahoo.com
2. Lamicchane K. Nirmal1, Dr., MD, drnrmalam@hotmail.com
3. Shakya R. Rabi1, Dr., MD, shakya_rabi@yahoo.com
4. Shakya Ratna Dhana1, Dr., MD, drdhana.shakya@yahoo.com

Objectives: To find out psychiatric morbidity among people working abroad who attended psychiatry service.
Methodology: This is a descriptive, cross-sectional study of 30 subjects receiving psychiatric services at BPKIHS, a tertiary care centre at eastern Nepal. An informed consent was obtained before administering a standard questionnaire which covered all relevant information including diagnosis. The final diagnosis by the consultant psychiatrist based on ICD-10 (WHO, 1990).
Results: Of 30 subjects; (90%) was male below 30 years with mean age of 27.97± SD 6.97, married (66.75%), literate (76.7%), and were from rural areas (63.3%). About 60% had gone to Gulf countries for job and majorities were employed as menial workers (70%). All subjects presented with some vegetative symptoms, 73.3% had anxiety feature, 56.7% had low mood, 13.3% had elevated mood, 50% had psychotic features and 50% had other symptoms in the form of headache, multiple physical complaints. About (20%) had history of substance abuse while 16.7% presented with intentional self harm. Majority (56.7%) had primary mood disorder and 6.7% had co-morbid mood disorder. About 44.0% subjects were managed in inpatient and outpatient (50%), under psychiatry and rest were in medicine department.
Conclusion: Majority suffered from major mental illnesses- schizophrenia, Bipolar disorder, severe depression and other psychotic disorders, supporting that a change in place of residence with its socio-cultural differences is known to play a role as stressor in precipitating & developing psychiatric illnesses.

7. Rutja Phuphaibul7, Dr, PhD, raphr@mahidol.ac.th

Objectives: To investigate the predictive factors for early language delay at age 2 years based on the Prospective Cohort Study of Thai children.
Study design: A prospective cohort study: secondary data retrieving.
Subjects: Total of 3,905 children was recruited based on 4 communities and 1 hospital in five areas of Thailand.
Material and Method: Language Development Survey was performed to identify children with early language delay at age 2 years. Logistic regression analysis was used for investigation the association between possible factors (both biological and environment factors) and early language delay.
Main outcome measure: Children with early language delay at age of 2 years.
Results: The incidence of early language delay at age 2 years was 11.68%. Factors strongly linked to early language delay were birth weight ≥2,500 grams (Odds ratio =0.41, 95% Confidence interval =0.29-0.61), gender, female,( Odds ratio =0.54, 95%, CI=0.37-0.60), 1st or 2nd birth order (Odds ratio = 0.53, 95%, Confidence interval = 0.31-0.93), the first word within 1 year (Odds ratio = 0.44, 95%, Confidence interval = 0.35-0.56), first step walking within 1 year (Odds ratio = 0.74, 95%, Confidence interval = 0.58-0.95) and study site, district areas (Odds ratio = 0.42, 95%, Confidence interval = 0.32-0.54). There was no clear evidence for a link between breastfeeding and early language delay.
Conclusions: Significant factors should be strongly concerned for clinical practice in counseling and treatment planning.

1. Karen Raine1, Ms, RN, M.Couns., Karen.Raine@doh.health.nsw.gov.au

Through a whole of government, family focused strategy, the NSW Department of Health has developed and partly implemented a universal psychosocial assessment and depression-screening model for all women expecting or caring for an infant. This model is now known as SAFE START. First phase implementation revealed that attention to universal perinatal mental health assessment and screening processes in the absence of matched attention to integrated service development for vulnerable families created multiple systemic problems. What became evident was that various health jurisdictions did not share a perception of the systemic change required for implementation of SAFE START.

This poster outlines a series of tools that are being utilised to engage key players in complex health systems to measure how change has previously been managed and predict key leverage points to accelerate further implementation of SAFE START. These tools include assessment of individual readiness for change, sponsor commitment, change agent capability, organisational stress, cultural behaviours and alignment of reinforcement/rewards with performance expectations.

Diagrammatic representation showing acceleration of implementation methodology across maternity, child and family, mental health, drug and alcohol, indigenous and multicultural health services form the core of the poster. Integrated care pathways for vulnerable families identified through universal perinatal psychosocial assessment and depression screening are represented in the context of integrating strategic directions in mental health policy frameworks. Specifically, integration of parenting for mental health and children of parents with a mental illness (COPMI) policy frameworks pertaining to the 0 - 3 age group.

PSYCHIATRIC MORBIDITY IN HIV POSITIVE PATIENTS IN INDIA

INSTITUTIONS
1. CSM Medical University, PSYCHIATRY, LUCKNOW, India

AUTHORS
1. A Rana1, Dr, MD, dranantrana@gmail.com
2. S Sharma1, Dr, MD
3. J K Trivedi1, Dr, MD

Aim: To find out psychiatric morbidity in HIV positive patients attending HIV clinic in Lucknow (INDIA)

Method: 107 registered HIV positive patients attending HIV clinic in the department of medicine were assessed for psychiatric morbidity. 60 item GHQ-12, SCID-I, SCID-II, MMSE, and DSM-IV were applied. Methodology, detailed result will be discussed in presentation.

Result: 66.7% subjects had current axis-I diagnosis. Most common diagnosis was mood disorder. 18% subjects had axis-II personality disorder and most common was antisocial personality disorder. Symptomatic HIV positive patients (AIDS) had statistically more psychiatric morbidity then asymptomatic HIV positive patients.

Conclusion: Result of the study in INDIA is comparable to other studies world wide. We can infer that every HIV positive patient should be assessed for psychiatric morbidity, because psychiatric problems are associated in high percentage in HIV patients.

Background: Social intergenerational mobility among patients with schizophrenia from Austria, Poland, Lithuania, Georgia, Pakistan, Nigeria and Ghana was compared.

Method: Socio-economic status (SES) of patients (N=1080) and their parents was defined by occupation as in the population census of their home-countries.

Results: Among patients with schizophrenia there was a constant downward drift, commonly to unemployment. This social decline was much clearly more distinct within the developed post-modern or modern European countries compared to the traditional Asian and African countries.

Conclusion: Two reasons for these findings are discussed:
1. Better course of illness in developing countries
2. Efficient family networks providing employment also for less productive family members

MAKING SENSE OF DIAGNOSTIC VALIDITY IN PSYCHIATRY

INSTITUTIONS
1. Medical School - State University of Campinas (UNICAMP), Department of Psychiatry, Campinas, Brazil

AUTHORS
1. Adriano C. T. Rodrigues, Dr., MD, MSc, adriano@fcm.unicamp.br
2. Cláudio E. M. Banzato, Dr., MD, PhD, claudio@lexxa.com.br

Background: When applied to classificatory and diagnostic concepts in psychiatry, two higher-order and non-redundant functional subtypes of validity, namely ‘nosologic validity’ and ‘diagnostic validity’, should be recognized. Whereas the former refers to how sound and empirically grounded the diagnostic categories are (by being discrete, robust or pathophysiologically understood), the latter refers to their appropriate-ness to identify what they are meant to. However, while nosologic validity is usually considered a key issue concerning psychiatric diagnostic and classificatory tools in general, the acknowledged lack of gold-standards for evaluating psychiatric nosographic categories often hinders investigations of their diagnostic validity.

Objective: Here we aim at showing in which sense diagnostic validity is a pertinent and valuable index of the quality of psychiatric diagnostic categories, as well as the basis on which it should be evaluated.

Method: The logical relation between tests and standards, and the meaning of both these terms are considered. Additionally, nosographic categories are analyzed within a ‘formation of concepts’ framework, in order to reveal some legitimate references in which regard their diagnostic validity can be appraised.

Results: Nosographic categories should also be considered vis-à-vis their diagnostic validity. Diagnostic categories are provisional scientific concepts and interact dynamically with various sorts of data in an inductive-deductive permanent flux. The interaction between diagnostic categories and the data associated to them provide the standards in which regard categories should and indeed often have their diagnostic validity analyzed in a tacit manner. Appropriate ways to perform such evaluation are discussed.

CAN A DIAGNOSTIC ASSESSMENT HAVE THERAPEUTIC EFFECTS?

INSTITUTIONS
1. Espace Jeunes Adultes (Société Parisienne d’Aide à la Santé Mentale), Paris, France

AUTHORS
1. Francis Rouam1, f.rouam@free.fr

Taking care of people suffering from mental illnesses generally implies two stages. First, treating the pathological process. Then, taking into account its consequences in their daily lives, especially regarding their jobs and their relationships. This is often considered as a matter for social rather than medical intervention. Nevertheless, in our opinion, this classic conception must be challenged in as much as psychiatric treatments and reintegrative processes are closely linked. Actually, on the one hand, the psychological state of patients depends on the effects of the pathological process on their earlier libidinal developments and object relations. On the other hand, identifications, narcissistic stability, adaptability, cognitive abilities, and various aspects of their current relationships are key factors in mental health. The assessment of our patients consists in a psychiatric diagnosis, the anamnesis of the main stages of their lives and their illnesses, IQ, personality and school skills tests. Their family circles must be considered as well as their previous vocational training and knowledge of the world of work. The achievement of this assessment by several members of the medical team makes the patients feel more structured and helps them to acquire a more accurate reflection and representation of themselves, which contribute to a better insight as a result. Moreover, they acquire a more precise understanding of their mental problems, become more critical about their vulnerabilities and their illnesses, even though some aggravation occurs. Furthermore, their capacity for resilience increases. To conclude, that is why diagnostic assessments can have essential therapeutic effects.

ACCEPT TO EXECUTE CONDITIONED REFLEXES: ORIGIN OF SOCIAL IDENTITY OR NON-BEING

INSTITUTIONS
1. CENTRO DE INVESTIGACIÓN, DIFUSION Y PROMOCION DE LA LIBERTAD INTERIOR (CIPLI), RESEARCH, Guatemala

AUTHORS
1. Nicolasa Sabatilga1, DR

Objective: Demonstrate that execution of conditioned reflexes (an alternative to avoid the appearance of internal contradictions) has a main purpose to adapt or to reincorporate, the Man, into social group.

Method: Study and record of those consciousness states produced in the real I search, during 3 decades.

Results: The child rebelliousness, for trying To Be Himself, provoking conflicts with his progenitors, the survival instinct (in front of punishment) push him surrender; with which, pleased they, annulled contradictions and executed recompense, he learns that negating him (while he executes extrinsic needs to his nature), it is a basic condition to become Himself. Time later, all that turned into unconscious conduct pattern, after foreign ideas and impulses to his essence, like is the obsession-compulsion, he will just have consciousness of the real mechanization of his act. Nevertheless, that natural inertia fixed in his meats, inextinguishably and indomitably pushing him to be Himself, this great daily tension only will be solved to renounce to the Being, executing conditioned reflexes: The religion miracle.

Conclusion: The execution of conditioned reflexes although avoids a social non-adaptation, appearance of internal conflicts and ‘Mental Illness’ on the other hand propitiates a gradual regression: A connotation of ‘normality’, for the frequent.

6. Juan Jose Sanchez Ruano

Objectives
The neuropsychiatry effects of the interferon treatment occur in more than 20% of the patients treated for hepatitis, although in some studies this number grows up to 50%, fundamentally referred to depressive clinic. We have done a prospective study to research the incidence of depression during the treatment period and its risk factors. We also analyze if factors such as age, sex, how they acquired hepatitis C, antecedents of the depression, act like risk factors in the greater depression.

Method
Fifty-six patients (33 males and 23 females) with diagnosis of chronic viral hepatitis based on positive markers and on liver biopsy being treated with IFN have been monitored by the department of psychiatry before starting the treatment and once a month until the ending of it, using The Beck Depression Inventory and habitual psychopathologic exploration.

Results
We will compare the medical and social-demographic characteristics of the patients with clinical depression (37%) and under antidepressants treatment, according to the judgment of the DSM-IV-TR and of those without it. No significant differences were noted between patients with and without depression.

Conclusions
Some studies are in favour of the idea that those patients that suffer an increase in depression produced by interferon, in our sample it has not appeared. The adherence to the treatment without necessity of lowering the dosage and the early abandoning of this one, provides a higher virology answer, that's why the importance in close monitoring for the early detection and the careful attack of the psychiatric symptoms.

DO WE KNOW ALL THE SYMPTOMS OF SCHIZOPHRENIA ?

INSTITUTIONS
1. Miyoshi Hospital, Psychiatry, Miyoshi City Hiroshima Pref., Japan

AUTHORS
1. Yasushi Sasaki, Mr., MD, PhD., joy123@mail.goo.ne.jp

Purpose: In 1999, the author had previously reported at WCP the existence of the fourth category of primordial delusion, which is experienced with perception (phenomenon) but cannot be expressed verbally. The author called this “pathological mood on phenomenon (PMP)”. When a background mental activity in the unconsciousness combines with PMP, it may become unusual and can gain attention. The purpose of this report is to determine whether such background mental activities (eg. emotion and will) in the unconsciousness can gain attention and enter into consciousness by the action of PMP.

Method: The author examined patients with autochthonous emotion and/or autochthonous will, and observed their symptoms.

Discussion: Up to now, autochthonous emotion and autochthonous will have not been well documented symptoms. However, some patients have shown autochthonous emotion or autochthonous will. The existence of these symptoms shows that emotion and will can arise pathologically, which suggests that PMP can produce some pathological phenomena.

Mental disorders are one of the most problems in the world and influence on medical disease thus this study investigated the prevalence of mental disorders in medical wards of Beheshti hospital.

Method and materials: this study was a descriptive research in 260 patients hospitalized in medical wards of Beheshti hospital. Data was collected in two groups: 1- identification data includes: name, age, gender, marital status, resident place and previous mental disorder and type of medical ward. 2- G.H.Q. Those who scores were higher than the cut off point in GHQ, were psychiatrically interviewed based on DSM-IV TR criteria.

The results were analyzed by descriptive statistic. Result: 54.2% suffered from mental disorder include: mood disorder (34.2%), anxiety disorder (9.6%), somatoform disorder(1.5%) and psychosis(0.4%). The rate of illness in female was 56.9% versus 42.7% in male. Prevalence of psychotic disorder is more than findings of Higashi and Yashiro (27 to 39%) and Koeng in Duke university (36.5% MDD)

Conclusion: Mental disorders are common in general hospital and consult with psychiatrist and liaison psychiatry is very important.

According to Angst, the more frequent comorbidities of Bipolar I disorder are panic disorder, social phobia, substance abuse / dependence, somatization disorder, personality disorders, suicide and delinquency, and also the attention deficit hiperactivity disorder (ADHD) The comorbidity of personality disorders and the affective disorders have gained interest in the last decade. Medical comorbidity (Axis III) will also influence the development, course and prognosis of Bipolar I disorder.

Objective: To carry out a complete evaluation of the patient, focusing specially on medical and psychiatric comorbidity besides the evaluation of his/her current mood.

The sample is composed by 120 patients diagnosed of Bipolar I disorder as defined by DSM-IV-TR. The diagnosis was made the psychiatrists participating in the study. We contacted the psychiatrist entrusted of the patients in order to inform them about the study and ask for their participation. The selected patients who gave their informed consent complete a clinical interview, including sociodemographic and clinical data.

Results: 84% of the sample don't show any Personality Disorder (PD). Among those suffering from a PD, the most frequent was Borderline Personality Disorder (4.4%). Regarding Axis III, 43.4% of the patients suffer from a medical condition, being the most usual endocrin-metabolic diseases (18.8%) and respiratory disorders (9.2%).

Conclusions: It will be necessary in the future to evaluate the relation between Bipolar and other comorbid disorders and their influence both in the course of the disorder and in the treatment response. Therefore, Bipolar disorders comorbidity requires a special attention, mainly regarding its etiopathogenetical, diagnostical, prognostical and therapeutical implications.

AUTHORS
1. Sara M T Sgobin1, Dr, MD, sara.sgobin@gmail.com
2. Claudio Banzato1
3. Elias Chaim1
4. Mariza Zancaner1

ACM, 27 year, female, with morbid obesity (BMI 46.8), arterial hypertension and orthopedic conditions. The patient was submitted to a routine presurgery psychiatric evaluation and was diagnosed with borderline personality disorder according to the DSM-IV. She presented suicidal behavior, impulsivity and preoperative expectations unrealistically high. Because of that, the surgery was temporarily postponed. She was treated with fluoxetine 20mg and was referred to psychotherapy, attending two sessions a week for about one year. Subsequently, she was submitted to a second psychiatric evaluation and found to be mentally better. In December 2005 she underwent gastric bypass surgery and since then has been followed-up. Two years after the procedure, the patient remains without clinical and psychiatric complications. Current BMI is 26.5.

Discussion: Morbid Obesity, defined as BMI>40, has been growing to a major health problem. Because of the relationship of morbid obesity with other severe illnesses, attention has been focused on methods for producing weighting loss. Conventional approaches have proven unsuccessful for the morbidly obese leading to the development of surgical alternatives. The comorbidity between morbid obesity and mental disorders is certainly far from rare. So this case draws attention an important issue: the conditions for indicating bariatric surgery for patients with severe mental disorders. Although patients with acute mental disorders may have a worse prognosis, mental illness should not be considered an exclusion criterion for bariatric surgery. This case suggests that prognosis may be improved if appropriate mental care is provided. The importance of a presurgery psychiatric evaluation is thus reinforced.

DUAL DIAGNOSIS PATIENTS IN A COMMUNITY BASED GENERAL PSYCHIATRY SERVICE: PRACTICAL DIFFICULTIES & GROUND REALITIES

INSTITUTIONS
1. Queen Elizabeth Psychiatric Hospital, University Department of Psychiatry, Birmingham, United Kingdom
2. St. Brigid’s Hospital, Psychiatry, Ardee, Ireland

AUTHORS
1. Rehan A Siddiquee¹, Dr., MRCPsych, rehan_007@hotmail.com
2. Tariq Siddique², Dr., MRCPsych

Managing patients that come under the umbrella term “dual diagnosis” is a big challenge to Psychiatrists and Psychiatric Services. Although solutions and guidelines for their management are recommended by various psychiatric organisations it is not always possible to implement them on the ground.

A perusal of the cases in a Community based Mental Health Team covering an urban population was done and all the cases that could be diagnosed with substance abuse under the ICD-10 were included. The case notes were screened by two qualified psychiatrists with membership of the Royal College of Psychiatrists, London.

Of the 285 cases that were under the care of the North Wrekin Community Health Team, 17 qualified as dual diagnosis patients. Although this was 6% of the case load, these patients utilised a significantly larger proportion of the available resources.

77% these of patients had poor concordance to their treatment plan, 89% were not involved with an addictions service.

Alcohol abuse was the commonest (70%) followed by cannabis (17%) benzodiazepine (6%) cocaine (6%) and poly drug abuse stood at 11%. There was an overlap because some patients abused two substances concurrently.

The associated psychiatric disorders were Schizophrenia/Psychosis (47%) depression (23%) bipolar disorder (17%) anxiety (17%) personality disorder (6%) and Wernicke/Korsakoffs (6%) Some patients had more than one psychiatric diagnosis.

The poster will highlight further correlations between the substance abused and the associated psychiatric diagnoses, highlight the existing gap between recommendations and available resources and give suggestions to improve treatment outcomes for these patients.

INFLUENCE OF THE HOLY MONTH OF RAMADAN ON ADMISSIONS IN THE MENTAL HEALTH HOSPITAL IN TUNIS

INSTITUTIONS
1. Al Razi mental health hospital, psychiatry F ward, Mannouba, Tunisia
2. Pasteur Institute, preventive medicine, Tunis, Tunisia

AUTHORS
1. Oussama Sidhom¹, Dr, MD, oussama_sidhom@yahoo.fr
2. Azza Klibi¹, Mrs
3. Rym Rafraf¹, Dr, MD
4. Nissaf Ben Alaya², Dr, MD
5. Sawssen Bouhlel¹, Dr, MD
6. Wahid Melki¹, Dr, MD
7. Zouhair El Hechimi¹, Dr, MD

Aims/Objectives:
Muslims fast each year during a whole lunar month called Ramadan (Islamic calendar). A decrease in the number of admissions was noticed during the Holy Month in many psychiatric wards. The aim of this study was to assess the influence of the month of Ramadan on admissions in psychiatry.

Methods:
The administrative data base of Al Razi mental health hospital in Tunis was checked for the following data over the last five years (2002-2006): the monthly and annual number of admissions as well as the monthly and annual rates of the different legal modalities of admissions (voluntary or coerced). Data were considered for the administrative (solar) months and the month of Ramadan.

Results:
There were significantly fewer admissions in Ramadan when compared to the rest of the year (p=0.001) but the number of admissions during Ramadan tends to approach the mean monthly rate in the last years. Considering the legal modalities of admission, we found a progressive annual increase in coercive admissions only, without any particular monthly pattern. These results were constantly found over the five studied years.

Conclusion:
The month of Ramadan appears to play a stabilizing role in, at least, some categories of mental disorders as proven by the decrease in the number of admissions. This effect is very likely due to the better familial care inherent of the general improvement of social binds characterizing the Holy month. This positive effect seems to be fading with time probably due to societal changes in relation with globalization.

8. Herrán Silva⁷

Aim: Working memory refers to transient representation of task-relevant information, and it is crucial for the development of complex, goal-oriented behavior. It has been found to be impaired in some psychiatric disorders and to be associated with the functional outcome of patients. In Borderline Personality Disorder (BPD), a severe mental disorder, previous studies suggest that memory systems may be affected, but a specific neuropsychological profile has not been established. The purpose of this work was to evaluate the performance of a group of BPD patients in a working memory task and to compare it to that of a group of individuals without psychopathology.

Methods: We evaluated a sample of 85 individuals, 51 patients with BPD and 34 controls, using the Tower of London (Drexel University Version) task and analyzed the data using latent class cluster analysis. The clinical evaluation included the IPDE interview to diagnose BPD, a semistructured psychiatric interview to exclude Axis I pathology, as well as structured impulsivity and aggression measures.

RESULTS: The model that best fitted the data was a three class model. One class was formed exclusively by controls, while BPD belonged to two different classes. 79% of the patients had a performance on the task that was indistinguishable from that of controls, while 21% of the patients performed significantly worse on the task.

CONCLUSIONS: This study suggests that neuropsychologically BPD is heterogeneous.

AUTHORS
1. Alicia Navarro de Souza, Dr., PhD, alicia@hucff.ufrj.br
2. João Ferreira da Silva Filho, Dr., PhD, jferreira@ccsdecania.ufrj.br

Objectives: This study dealt with the psychosocial impact of genetic risk in breast cancer patients participating in research on BRCA 1 and BRCA 2 mutations in a public university hospital.

Methods: Fifty patients were interviewed during medical consultations conducted by breast surgeons, during which time genetic risk factors were explained. They were later interviewed by a psychiatrist and their understanding and risk experience were investigated. All the interviews were recorded in audio, transcribed and organized according to content discourse analysis.

Results: Amongst the fifty patients invited to participate in the research, 100% gave informed consent, 42% without further inquiries. From the remaining 58% (who asked questions), 46% asked about the research and 12% about aspects related to diagnosis and prognosis. Semi-structured interviews later undertaken by the psychiatrist showed that only 58% of the patients understood the research; 56% had commented on it to family members; only 18% were concerned about genetic risk factors.

Conclusions: Patient participation with informed consent, which considers values such as competence, autonomy and citizenship, was not enough to convey an understanding of genetic risk. This shows the paternalistic doctor-patient relationship values which are prevalent in our public health system. Even though genetic information seen as being empowering, as a promise of conditions for the control of future health conditions, most breast cancer patients didn’t experience mutation research as enabling them to act as “responsible genetic subjects” towards children and other relatives.

AFFECTIVE PATHOLOGY IN CLINIC WOMEN ORGASMIC DISORDERS

INSTITUTIONS
1. Moscow scientific research institute of psychiatry, Sexology, Moscow, Russian Federation

AUTHORS
1. Natalia Stenyeva, Mrs, nataliasten@mail.ru

The purpose of the present research was to study interrelation of various cases of orgasmic disorders and an affective pathology as a way to optimize medical rehabilitation tactics for patients with the given pathology. The work is based on the results of clinical study of 83 patients with orgasmic disorder, who passed inspection and treatment in sexual pathology department starting from 2000 to 2006. The basic methods of inspection were clinic-sexological and clinic-psychopathological, with the use of standard personal techniques of inspection.

Women orgasmic dysfunction was formed on a background of various affective pathologies within the limits of frustration of mood and neurotic frustration. Orgasmic disorders occurred with the patients with easy and moderate depressive episodes on a background of frustrated libido and was shown as advanced secondary coital hypoorgasmia in some cases resulting in total anorgasmia. Among patients with adaptation infringement orgasmic dysfunction was leading to sexological frustration and declared itself as secondary coital hypo-anorgasmia. Among patients with conversional anesthesia and loss of sensual perception orgasmic disorder was formed in the form of total frustrational secondary anorgasmia. In case of neurasthenia orgasmic dysfunctions developed themselves simultaneously with the infringement of libido as an advanced secondary total hypo-or anorgasmia. The choice of orgasmic disorders therapy was defined by a leading affective pathology and represented a combination of pharmacotherapy, various psychotherapeutic techniques and sexual therapy of an individual and orientation of the couples. Similar tactic of treatment is an effective method of correcting women orgasmic dysfunctions.

THE ATTITUDE OF SCHIZOPHRENIC PATIENTS AND THEIR FAMILIES TO ALTERNATIVE MEDICINE

INSTITUTIONS
1. Clinic for Mental Health Protection, Nis, Serbia and Montenegro

AUTHORS
1. Zagorka Stevanovic¹, Dr, sphtop@bankerinter.net

In the countries with western-type health protection, which is based on scientifical medicine, novices and experts alike are becoming interested, in the last decades, in all types of different treatments, which aren’t practiced in the official health system. Alternative (traditional) medicine is mostly defined as all known practice of treatment given to the sick people, and others, which exists, side by side with the practice of official medicine. There are four kinds of traditional healers but they can be divided into four groups: 1. Herbalists are concerned mainly about plant remedies, some of which are known to contain active ingredients while others appear to be placebos. 2. Medicine men and women use verbal or ritual methods of healing, sometimes combined with plant remedies. They are believed to have special powers, often of supernatural origin. 3. Shamans use methods like those of medicine men by also enter into altered states of consciousness in which they are believed to communicate with spirits or ancestors, and to recover the abducted souls of people made ill by this supposed loss. 4. Diviners discover and name the cause of illness by interpreting oracles, from the content of dreams, or through some form of communication with ancestors or spirits.

In our work we were investigating the attitude of schizophrenic patients and members of their families to alternative and/or traditional medicine: if they, and in which phases of illness, asked help from traditional healers, what kind of treatments were they subjected and what is their attitude now.

2. Ana F Fernández², MD, anafarfalina@gmail.com

HIV/AIDS epidemic imposes a high impact on health care systems. Prevention of HIV infection is still the most important measure of control. Modification of sexual behavior is the only effective strategy today. Sexual behavior could be divided in two: planned and controlled sex (use of condoms and monogamy) or impulsive and irresponsible sex (unsafe). The presence of personality disorders interfere with an HIV infected individual safe sexual behavior, independent of sexual orientation. Diagnosis of these pathologies would allow us to develop more effective strategies for the prevention of HIV/AIDS. The authors aim to establish the relationship between the diagnosis of personality disorders, sexual risk behaviors and HIV infection. We will select a sample of 25 men who have sex with men, between 18 and 45 years of age, with a diagnosis of HIV infection of at least 6 months, asymptomatic, with no DSM-IV axis I psychiatric comorbidity who will attend the Community Services Center of Action For Solidarity Foundation and the Venezuelan Social Security Institute Immunology Center, in Caracas, Venezuela. Participants will be clinically interviewed and complete: the modified Graffar socioeconometric index, the Hamilton and Beck depression scales, the Structured Clinical Interview for DSM-IV (SCID-II), the Millon Clinical Multiaxial Inventory - Third Version (MCMI-III) and the modified CAP Poll on HIV/AIDS. We will apply to the results the appropriate statistics to carry out the final analysis. Our ongoing study is scheduled to be completed in June 2008.

Objective: This study propose to know the process of recognizing lesbian and the experience of this orientation sexual

Method: It is a qualitative study. The participants of this study were women with ages above of 19 years that self-identified as lesbian and lives in south of Brazil. The selection of the participants was made through the technique Snowball Sampling. The first interview started in a contact with an ONG that defends the free sexual expression. For the gathering data we used narrative interviews and they were analyzed according to the principle of discourse analysis.

Results: The data revealed that the recognizing lesbians' sexual orientation is a gradual process of break of personal paradigms and of our society compulsory heterosexuality; being necessary the creation of new social, educational and family spaces that increase this new reality.

Conclusion: A new women's history is necessary to be recounted, therefore our society, still predominantly in compulsory heterosexuality and patriarchal needs to enlarge their spaces for the expression of this diversity, in spite of several efforts for the change of this paradigm.

1. Bjarte Stubhaug¹, Mr, MD, bjarte.stubhaug@psybp.uib.no
2. Ole J Hovland¹, Mr, PhD, olehovl@online.no
3. Stein A Lie², Mr, PhD, stein.lie@unifob.uib.no
4. Holger Ursin², Mr, MD, PhD, holger.ursin@unifob.uib.no
5. Hege R Erikson², Ms, PhD, hege.eriksen@unifob.uib.no

Objectives
To study the prevalence of personality disorders and patterns of personality factors in patients with Chronic Fatigue Syndrome (CFS).

Methods
Patients with CFS (n=62) were interviewed using SCID-II and fulfilled questionnaires of Personality Assessment Inventory (PAI) prior to a treatment intervention program. Patients were examined at 5 years follow-up after treatment, recording fatigue symptoms and improvement after 5 years by self-reported Fatigue Scale.

Results
The prevalence of personality disorder was low (13 %), equal to non-clinical populations. The mean personality score by PAI was 51 (norm T=50), indicating low average personality dysfunctions. The CFS patients had a clinical profile most similar to that of somatoform disorder (Coefficient of Fit = .667). There were elevated scores of somatisation and health concerns and on subscales of vegetative signs of depression, and low scores of self-esteem and perfectionism. Low improvement by 5 years follow up was associated with low levels of perfectionism and high levels of vegetative signs of depression.

Conclusion
Patients with CFS seem to have personality disorders and personality pathology level equal to the average population. CFS patients had a tendency to higher levels of somatisation and somatic complaints, more vegetative signs of depression, lower self-esteem and low level of perfectionism. This could be secondary to the CFS illness, possibly explained by physiological and cognitive sensitisation processes.

A PATHOLOGICAL FEELING OF ISOLATION RELATED TO AWAKENING OF SCHIZOPHRENIA

INSTITUTIONS
1. Surugadai University, Division of Psychology, Department of Modern Culture, Hanno, Japan

AUTHORS
1. Kyoko Sumida¹, Dr., Md, sumidagawa_k@yahoo.co.jp

Although there is no final agreement about the definition of so-called “awakening” in schizophrenia, its clinical significance as a chance of recovery, as well as a crisis of survival, has been known for a long time. The most critical point is a risk of suicide, which tends to be overlooked in the empirical research on the introduction of, or the switching to, atypical antipsychotics but to be emphasized in the descriptive research mentioning anecdotes and clinical cases. The following crucial factors in suicidality are suggested: 1) insight into the illness with stigmatization, 2) confrontation with reality, and 3) elevation of volition. The first and second factors lead the patients to contemplation of suicide, and the third facilitates their execution of it. This mechanism itself can be explained with normal psychology. However, there may be still other pathological aspects. We have indicated that in some cases the patients confronted a reality that was not the living world in common with others but a desolate world of absurdness.

In this presentation, the concept of a pathological feeling of isolation will be abstracted from narrations of patients on awakening by the method of grounded theory. This feeling is related to the pathological aspects of awakening mentioned above and is assumed to be connected with suicidality. In order to search for a psychotherapeutic strategy, the nature of this feeling shall be analysed by referring to the analogous states depicted in epistemological philosophy, object relations theory, and Zen psychology.

RESPONSIBILITY INTEGRAL TO PSYCHIATRY

INSTITUTIONS
1. Otago University, Christchurch School of Medicine, Christchurch, New Zealand

AUTHORS
1. Daniel Svoboda¹, Dr, daniel.svoboda@chmeds.ac.nz

Individual Responsibility is fundamental to civilised society and professional practice, including psychiatry. However, psychiatry underutilises the concept of responsibility in actual clinical practice, perhaps, because of a lack of an established conceptual framework. A theoretical account of responsibility and its utility will be presented. This will include its necessary foundations, with some examination of competing models. A biological - developmental dimension will be given. Relating responsibility to associated terms including choice, motivation, judgement, intention and volition will be explored. An account of its normal and psychopathological aspects relevant to patients’ histories and mental state examination will be discussed. A number of clinical scenarios, across the age spectrum, will be presented to demonstrate the conceptual relevance of assessing for and utilising responsibility. Forensic aspects will be addressed briefly. It is proposed that a conceptual and therapeutic use of responsibility could augment other therapeutic measures undertaken by clinicians.

ILLNESS EXPLANATION MODELS AND THEIR ANALYSIS IN JAPAN AND HUNGARY

INSTITUTIONS
1. Dinamimika Bt, psychiatry, Budapest, Hungary

AUTHORS
1. Gyongyi Szilagyi, Dr, szilagyigy@consultant.com

The purpose of our research is to compare the illness explanation models in two different cultures, one of them with a collectivist society (Japan) and the other one with an individualist society (Hungary). A Questionnaire, Explanation Models of Mental Illness (QEMMI - presented at the IACCP Congress 2003), developed by ourselves, has been used to understand the effects of patients’ explanation models on help-seeking pathways and compliance with a definite type of therapy as well as the Dependency-Interdependency Scale to define the scale of the dependency and interdependency in both societies. Our field of research is based on existing healing methods in Hungary and Japan. Main topics of QEMMI: mental illness explanation model, treatment model, satisfaction with treatment, believes in the treatment plan, compliance, help-seeking pathways, received education on the model.

In each treatment model 50-60 patients completed QEMMI and the Dependency-Interdependency Scale. We studied the differences and similarities of cultural and sociological influences on the explanation models of patients and therapists. It has been shown, that a fit between the models of patients and therapists was more relevant in the case of patients with a high interdependency need and in most cases was very efficient in patient compliance and satisfaction.

DIABETICS TREATED IN PSYCHIATRIC AMBULANCE

INSTITUTIONS
1. Doctor, Psychiatry, Plzeň, Czech Republic
2. Doctor, Internal Medicine, Plzeň, Czech Republic

AUTHORS
1. Jana Šabaková, Dr., sabakovaj@fnplzen.cz
2. Zdeněk Rušavý, Dr., PhD, rusavy@fnplzen.cz

Objective: Diabetes mellitus is a chronic illness and its treatment is associated with many restrictions of patients’ life. Mental condition and diabetes are closely related and there is a provable mutual connection. Thus, the aim of the study was to demonstrate the importance and benefit of psychiatrist and psychologist involvement in a medical team that cares for diabetics.

Methods: All patients who have been visiting regularly psychiatric ambulance of the Diabetology centre for the period at least six months were observed prospectively. Therapy using psychopharmacs, psychotherapy and their combination was compared. Mental condition of the patients was assessed objectively and subjectively, glycated haemoglobin as a parameter of diabetes compensation was measured during the therapy and furthermore changes in therapy were given in account, both psychiatric and diabetological.

Results: The largest benefit has been found in diabetics who received combined treatment, i.e. psychotherapeutic treatment supported by psychopharmacs.

Conclusion: It is important for the systematic care of diabetics to involve both psychotherapeutic and psychopharmacological special treatments.

TWO CASES OF WRITER’S CRAMP ASSOCIATED WITH DEPRESSION

INSTITUTIONS
1. Jichi medical university, psychiatry, Shimotsuke-shi, Japan

AUTHORS
1. Eisuke Takano¹, MD, hidesuk-t@jichi.ac.jp
2. Yoshiro Okajima¹, MD, PhD
3. Satoshi Kato¹, MD, PhD

We experienced two cases of writer’s cramp with depression. Herein, we report the difference in diagnosis according to the DSM-IV-TR criteria. Case 1 was a 43-year-old man. He received a promotion 6 years ago and was transferred 5 years ago. Due to his increased workload and responsibilities, he felt tired, experienced headaches, suffered reduced motivation, and lost his appetite and concentration. Consequently, he was treated for depression. After hospitalization for 1 week, his headache and writer’s cramp improved, and two weeks later, his depression also improved. Case 2 was a 50-year-old man who received a promotion 2 years ago. His increased workload, workplace relationships, and responsibilities made him feel depressed and tired. He experienced headaches, insomnia, loss of appetite, and subsequently developed writer’s cramp. After hospitalization for 2 weeks, insomnia, loss of appetite, and writer’s cramp improved, and 4 weeks later, his depression improved.

The common factors observed in these 2 cases were promotion, workload, and relationship stress. For both cases, hospitalization improved depression and writer’s cramp. Case 1 had a typical past. Therefore, the writer’s cramp seemed to be the result of neurosis, stressful situations, panic disorder, or social phobia. However, in Case 2, writer’s cramp developed during depression. Therefore, it seemed to be related to tremor as an expression of anxiety symptom. Therefore, we thought that the depression and writer’s cramp were linked, and writer’s cramp was symptoms of anxiety of depression.

5. Ryoji Nishimura¹, Dr., PhD

Gender identity disorder (GID) is characterized by a discrepancy between objective born sex and subjective gender identification, expressed as a feeling of being born in the wrong sex. We call patients whose objective born sex is female FT M (female to male), and patients whose objective born sex is male MT F (male to female). Sex differences in certain cognitive abilities are well established. For example, men tend to excel in a targeting task, a mental rotation task, and a line orientation task, whereas women tend to excel in a verbal fluency task and a perceptual speed task. Haraldsen et al (2003) reported that the cognitive pattern of GID patients is consistent with that of their biological sex and not that of their gender identity. However, Egawa et al (2003) suggested that the cognitive performance of GID patients depends on their gender identity. The purpose of this study is to examine and analyze whether there are differences in cognitive abilities between gender identity disorder patients and the control group. FT M subjects were recruited from outpatients of the Fukuoka University Hospital and control subjects were recruited from female nurses working at Fukuoka University Hospital. We performed 6 sex-sensitive cognitive function tests to 20 GID patients and 20 control subjects. Measures of cognitive function included a targeting task, a mental rotation task, the Benton Judgment of Line Orientation, two verbal fluency tasks and the Pegboard task. In this presentation, we will discuss the typicality of sex-sensitive cognitive ability related to GID.

**CROSS-SECTIONAL STUDY OF THE CAREGIVING EXPERIENCE OF CHINESE IN-PATIENTS AND OUT-PATIENTS WITH SCHIZOPHRENIA IN HONG KONG**

**INSTITUTIONS**
1. Castle Peak Hospital, Hong Kong Special Administrative Region of China
2. The Chinese University of Hong Kong, Hong Kong Special Administrative Region of China

**AUTHORS**
1. Victoria WK Tang¹, Dr, MRCPsych(UK), vwktang@gmail.com
2. SK Leung¹, Dr
3. Linda Lam², Prof., MD

**Objective:**
To compare the experience of Chinese caregivers in caring for patients with Schizophrenia in the outpatient and inpatient setting.

**Methods:**
201 patients with schizophrenia and their caregivers were recruited from a list from a large general adult psychiatric clinic. Assessment took place in the clinic or on the wards if patients were admitted during recruitment period from February to July 2007. The caregivers completed the Involvement Evaluation Questionnaire (IEQ) 1. Patients were assessed by the PANSS and GAF. Correlation analysis was performed.

**Results:**
22 (10.7 %) patients were admitted during recruitment period. There was no significant difference between the age and sex of inpatients and outpatients, or the age of caregivers. The majority of carers of inpatients were female (81.8%), while females accounted for only half of the caregivers in the outpatient setting (53.6%). Admitted patients had higher PANSS scores (inpatient= 47.9, outpatient= 39.4 p<0.05) though there was no significant difference in the GAF. Caregivers for inpatients yielded higher scores in all four subscales of the IEQ (tension, supervision, worrying and urging) compared to outpatients, but only the tension subscale scores reached statistical significance (inpatient= 8.0 , outpatient= 3.0 p<0.01).

**Conclusion:**
Circumstances leading up to admission usually involved exacerbated psychotic symptoms and disturbing behaviour, which would increase interpersonal tension. Service planning should include assessment of caregivers, especially for female caregivers in households with significant tension, to identify at risk caregivers.

**RELATIONSHIP BETWEEN DURATION OF UNTREATED PSYCHOSIS AND OUTCOME IN FIRST-EpISODE PSYCHOSIS**

**INSTITUTIONS**
1. Hospital Magalhães Lemos, Departamento de Psiquiatria, Porto, Portugal

**AUTHORS**
1. Isabel Saavedra¹, Dr, MD, isabel.saavedra@sapo.pt
2. Pedro Teixeira³, Dr, MD, jpnovaisc@yahoo.com
3. Filipa Veríssimo¹, Dr, MD

There is evidence that the duration of untreated psychosis (DUP) correlates moderately with short-term symptomatic and functional outcomes in first-episode of psychosis. The authors review the predictors of DUP in a first episode patient population (n=30) and its implications in the clinical and functional outcome. The sample consists in a majority of male Portuguese speaking patients, single, unemployed, with substance abuse and average DUP of 102 weeks. The literature shows that shorter DUP is associated with greater response to antipsychotic treatment, as measured by severity of global psychopathology, positive symptoms, negative symptoms and functional outcomes.

Understanding the mechanism by which DUP influences prognosis may lead to better understanding of the pathophysiology of psychosis. We conclude that DUP may influence the response to treatment, reflecting a potentially malleable pathological process. In this regard, there is support for effective intervention programs in emerging psychotic illness.

PSYCHOLOGICAL DIFFERENCES BETWEEN PARAMYLOIDOTIC AND OTHER LIVER TRANSPLANTED PATIENTS AFTER TRANSPLANTATION

INSTITUTIONS
1. Faculty of Medicine/ University of Lisbon, Psychiatry, Lisbon, Portugal

AUTHORS
1. Diogo Telles-Correia¹, Dr., MD, tellesdiogo@gmail.com
2. Antonio Barbosa², MD, PHD
3. Ines Mega³

Background and Aims
Liver transplantation is, nowadays, considered the treatment of election for many patients with severe liver disease. Paramyloidosis is a very uncommon genetic liver disease almost only present in Portugal and about which very little has been published. We aimed to study the psychological differences between paramyloidotic and other liver transplanted patients one month after transplantation.

Methods:
We studied a liver transplant candidates sample (n=40), comprising consecutive patients attending out-patient clinics of a public liver transplantation Central Unit (30% of patients with paramyloidosis, 70% with other liver diseases) by means of DSM-IV diagnostic criteria, HADS (Zigmond 1983), Brief COPE (Carver,1997) and a multi-dimension adherence questionnaire (Telles-Correia 2006). A liver transplant candidates sample (n=40), comprising consecutive patients attending out-patient clinics of a Public Liver Transplantation Central Unit transplant candidates, was evaluated before and one month after liver transplantation.

Results and Conclusions
In the pre-transplantation period only 28% showed no lifetime psychiatric disorders in the past, and as current DSM-IV psychiatric diagnosis 25% showed major depressive disorder, 18% anxiety disorders, 11% adjustment disorder, 11% dependence/abuse of alcohol or other substances. Forty percent had moderate-high scores for anxiety and 36% for depression (HADS). There was a predominance of acceptance, active coping, use of emotional support, positive reframing, and planning coping strategies.

After transplantation, we found statistically significant differences between paramyloidotic and other patients concerning scores of anxiety/depression, coping mechanisms and multidimensional adherence. This conclusion emphasises the importance of a specific approach for each of these populations after liver transplantation.

AUTHORS
1. Nesrin B Tomruk¹, Dr, MD, tomrukn@superonline.com
2. Emre Tan¹, Dr, MD
3. Nesrin Karamustafalioglu¹, Dr, MD
4. Nihat Alpay¹, Dr, MD

Objective: Syphilis is still a common STD. Although use of antibiotics has altered the natural course and late-stage neurosyphilis (NSy) is seen in various clinical manifestations, it has also made a comeback in HIV (+) patients (1). Psychiatric symptoms may be the initial or major manifestations of thyroid diseases. Hashimoto's thyroiditis' cerebral complications are related to hypo/ hyper-thyroid state in most cases. Approximately 1/3 of cases are clinically hypothyroid at the time of diagnosis (2). This case report describes a rare comorbidity of NSy and Hashimoto's hypothyroidism.

Method: A case diagnosed as schizophrenia for ten years was further evaluated and the laboratory findings revealed two major organicities.

Results: 48 year old female patient, hospitalised 4 times in ten years with a diagnosis of schizophrenia. Serum VDRL was found positive in early stage and was treated with comorbid diagnosis of syphilis. Although atypical features, cognitive impairment and inadequate treatment response persisted, the patient was not further investigated for neurosyphilis. After a thorough investigation, neurosyphilis and autoimmune hypothyroidism have been detected.

Conclusions: Both neurosyphilis and hypothyroidism may cause confusion and cognitive impairment, the prominent features besides psychosis in this patient.

It is noteworthy that even in a patient treated with schizophrenia for a long time, significant and treatable organic etiologies could be detected.

THE MANIFESTATION CHANGE IN DEPRESSION AND THE INCREASE IN “HIKIKOMORI” IN JAPAN

INSTITUTIONS
1. Nagoya University, Psychopathology and Psychotherapy, Nagoya, Japan
2. Aichi-Shukutoku University, Nagoya, Japan

AUTHORS
1. Hitoshi Tsuda¹, Dr., MD, PhD, fwayne9645@mb.infoweb.ne.jp
2. Mami Suwa², Dr., MD, PhD

The current changes in psychiatric phenomena are rapidly shared among clinicians. These clinical findings reveal the essential value changes of our society. In Japan the following two prominent changes are found. 1) The decrease in typical endogenous manifestations of depression based on melancholic type personality (Tellenbach), and the increase in not full-fledged depression of maladjustment type among younger generations. 2) The increase in cases of hikikomori (social retreat), in which youngsters not only avoid their identity formation in the established society but also shut out any communication sometimes for years.

It was until the period of the high economic growth, that a value which guaranties seniority system was maintained. The seniority system is possible only when people adjust themselves to get their reward, delayed, long after the period of their real achievements. Also it endorses the conservative view of the value which ranks the position of people on the basis of their social credits. The people with melancholic type structure were well-fitted to this system, since these people hesitate to overtly claim their rewards, instead, they devote themselves to seek perfect achievement. The more the breakdown of the seniority system was evident, the more this type of personality became maladjusted already in their younger age. The breakdown of the system is also making clear that the basis of this social value was not substantial but fictitious. It can be considered that youngsters with hikikomori implicitly recognize this fictitious aspect and begin to avoid all social contacts which force them to conform to it.

2. Fátima Bottcher-Luiz², Dr., PhD, boluigi@terra.com.br
3. Egberto Ribeiro Turato³, Dr., PhD, erturato@uel.com.br

Objective: This study was carried out in a group of Brazilian patients, who presented Turner Syndrome or its variants forms. In adult subjects, this Syndrome affects basically the secondary sexual characters, leading to a typical picture of infertility.

Method: To evaluate the meaning of this condition in these women, the qualitative clinical method was applied by clinical psychological interviews at a 13 patients, who have had annual accompaniment in the sector of Gynecology. The quarrel was based on the psychodynamic theory.

Results:
1) Absence of the menstruation have been presented in all the patients of this group and demonstrated to be important for the psychic functioning of these women, according to perception of femininity, more than the reflections of the infertility.
2) The direction and the meaning of the femininity was not associated with the maternity and reproduction as isolated aspects, but was also coherent with the transformations of the modern World. Than, these women had demonstrated other desires and social representations, such as to study, to work and to get autonomy, independently of the social-economic level of the carriers.
3) The adoption of a child has demonstrated to be a possibility for the majority of them, although this alternative has not been offered to them, at any moment of the follow up.

Conclusion: We suggest the implementation of measures in addition to the prevention of the clinical manifestations, represented by psychological support.

5. Bahadir Bostan1, Dr, MD
6. Huri Aslan1, Dr, MD
7. Asli Erkan1, Dr, MD
8. Hasan Karadag1, Dr, MD

Aims/Objectives
The aim of the present study is to compare the diagnostic concordance between structured vs. unstructured interviews. The secondary aim of our study is to identify which psychiatric diagnosis were underdiagnosed with an unstructured interviews.

Methods
113 psychiatric patients who referred to inpatient care were evaluated for this study. All patients were evaluated with unstructured interviews at the out-patient psychiatric clinics of our hospital. After that in the in-patient period they were evaluated with SCID.

Results
Correlation coefficient between non-structured interviews and structured interviews were modest (r=0.537, p<0.000). The highest diagnostic agreement rate was in patients with alcohol dependence (100%, 9 patients), lowest diagnostic agreement rate was in patients with bipolar disorders manic episode (%33.7, 11 patients). In standard clinical interviews simple phobia (3 patients) social anxiety disorder (1 patients) and schizoaffective disorder (2 patients) were underdiagnosed. We also found that 29 (26%) more patients were diagnosed with two or more DSM-IV axis I disorders when diagnoses were based on the SCID than based on standard clinical evaluation.

Conclusion
According to our findings standard clinical interviews is not as reliable as structured interviews in terms of making psychiatric diagnosis.

THEORETICAL UNDERSTANDING OF CULTURAL VARIABLES IN APPLYING EFFECTIVE PSYCHOTHERAPY IN NON-WESTERN SOCIETIES

INSTITUTIONS
1. Indiana University School of Medicine, Indianapolis, United States

AUTHORS
1. Vijoy K Varma1, Professor, vijoyv@comcast.net

The Western model of psychotherapy, though practiced across the world in different cultures, has come under increasing scrutiny and criticism lately. This particularly applies to dynamically oriented individual psychotherapy. It is due to advances in psychotherapy in non-western cultures and ever-increasing experience in trans-cultural psychotherapy. Numerous key factors unique to traditional societies have been identified that influence the nature and course of psychotherapy e.g. close and confiding relationship between doctor and patient (Guru-Chela paradigm), more permeable ego boundaries, dependency of patient, psychological sophistication, involvement of the family etc. To be effective, psychotherapy should be consistent with the social and philosophical background, cultural fabric, and belief systems of the people. Industrialization and adaptation of western concepts does not necessarily translate into the ‘traditional mind’ becoming a ‘western mind’. Cultural variables can be important and relevant even when the therapist and patient are from different ethnic groups. People from non-western cultures may not place the same degree of emphasis on talking as a form of treatment, introspection, exploration etc. but look for more directive instructions expected from therapist.

UTILITY OF PERSONALITY MEASUREMENT IN THE RECOVERY FROM SURGERY

INSTITUTIONS
1. Universidad de Extremadura, Area de Psiquiatria, Facultad de Medicina, Badajoz, Spain

AUTHORS
1. Maria Jesus Cardoso-Moreno, Dr., cardoso@us.es
2. Maria Isabel Ramos-Fuentes, Dr., miramos@unex.es
3. Francisco Jose Vaz-Leal, Dr.

OBJECTIVES: The aim of this study was to assess the impact of different psychological and/or biological effects in the recovery from surgery.

METHODS: The sample was composed of 42 patients admitted to the Surgical Unit of the Infanta Cristina University Hospital (Badajoz, Spain), waiting for a surgical intervention. Patients with cognitive impairment were removed from the sample. Prior to surgical intervention (48 to 72 hours), patients were administered the Millon Clinical Multiaxial Inventory-II (Millon, 1986) and salivary cortisol were measured 24 hours before surgery. Following surgical intervention, recovery was coded as good or poor according to Moix et al's criteria (1995). Dietary intake, resting and sleeping hours, as well as the existence of fever, perceived pain and related surgery complications were daily registered and controlled for.

RESULTS: The cortisol values were increased in patients with high score in Histrionic Scale (t = 2.10, p = 0.043). There was a significant relation between personality, cortisol and recovery. The patients with low score in Dependent Scale (t = 2.33, p = 0.029), Histrionic Scale (t = 2.51, p = 0.020), Alcohol Dependence Scale (t = 2.01, p = 0.049), Drug Dependence Scale (t = 2.08, p = 0.050) and cortisol show better recovery from surgery.

CONCLUSION: The results of this study indicate that psychological factors and levels of cortisol may have a critical role in post operatory recovery. Taking these data into account, it seems necessary to assess psychopathology on a regular basis in all the patients waiting for surgically interventions.

A BOTTOM-UP APPROACH IN PSYCHIATRIC DIAGNOSIS

INSTITUTIONS
1. Vincent van Gogh Institute for Psychiatry, Clinical Research, Venray, The Netherlands
2. Erasmus University Medical Centre, Psychiatry, Rotterdam, The Netherlands
3. Radboud University, Behavioural Science/Clinical Psychology, Nijmegen, The Netherlands

AUTHORS
1. Willem Verhoeven, Mr., MD,PhD, wverhoeven@vvgi.nl
2. Jos Egger, Mr., MSc,PhD, jegger@vvgi.nl
3. Siegfried Tuinier, Mr., MD,PhD, stuinier@vvgi.nl

Aims/Objects. Investigation of the etiology is not as a routine applied in the diagnostic procedures in clinical psychiatry. This practice is the consequence of the present diagnostic habits in which a diagnosis is based on consensus about a cluster of symptoms, mostly e causa ignota. This so called top-down approach severely hampers the development of psychiatry into a scientifically underpinned discipline.

Methods. At our outpatient department of neuropsychiatry special attention is given to developmental issues, level of cognitive functioning and dysmorphias.

Results. In about 5 percent of the patients routinely referred for neuropsychiatric evaluation, a genetic diagnosis could be established using cytogenetic analysis and FISH technique. Reasons for referral were: relapsing psychotic disorder: n=7, recurrent depressive disorder: n=4, personality disorder: n=3 and atypical autism: n=1. In 4 patients a diagnosis of 22q11 deletion syndrome was made. In another 4 patients de novo translocations were found. Two patients appeared to have an XXY karyogram of whom one in combination with Prader-Willi syndrome. In 2 patients cytogenetic analysis revealed a duplication. Other diagnoses were Rendu Osler syndrome (n=1) and Rubenstein-Taybi syndrome (n=1). In none of the patients the symptomatic profile fitted within a classical DSM diagnosis.

Conclusions. Patients with a known genetic disorder may, after adolescence, present with psychiatric symptoms that are more or less etiologically specific. The latter means that in such disorders an increase risk exists to develop several psychiatric syndromes that includes also developmental issues, neuropsychological dysfunctions and somatic/neurological comorbidities. Therefore a bottom-up diagnostic procedure is warranted.
Alexithymia: an endophenotype for Noonan Syndrome?

**Institutions**

3. Jos Egger2, Mr., MSc, PhD, jegger@vvgi.nl
4. Ineke van der Burg4, Mrs., MD, PhD, i.vanderburg@antrg.umcn.nl
5. Siegfried Tuinier1, Mr., MD, PhD, stuinier@vvgi.nl

**Objectives**

Noonan syndrome (NS) is a genetic disorder, characterized by short stature, facial dysmorphia and heart defects. Despite a prevalence of 1 in 1000 to 2500, virtually no research is found on psychiatric comorbidity and cognitive functioning [1]. A recent study suggests a lowered incidence of psychiatric disorders, but also provides evidence for a characteristic pattern of alexithymia [1]. To this end psychopathological features and cognitive measures are explored in a group of adult NS patients.

**Methods**

30 patients (mean age 27 ± 12.8) with a confirmed clinical diagnosis of NS underwent neuropsychiatric examination and (neuro)psychological assessment. Data on medical history, family history and development were collected, as well as measures of intelligence, social cognition, psychopathology, and quality of life, including evaluations of proxies.

**Results**

Mean IQ was just below average, but overall cognitive functioning appeared to be intact. In more than half of the patients, emotion identification and verbalisation defects were confirmed. A tendency was found toward social desirability, agreeableness, and subasertivity. Patients reported average levels of satisfaction with life in general, in contrast with the evaluation of their social functioning by significant others.

**Conclusion**

Alexithymia is more common in NS, whereas the incidence of psychiatric disorders per se is lowered. It is argued that psychopathology may still be present, but remains unseen because of problems in social cognition in combination with amenable personality traits.

**The term Executive Function (EF) refers to skills such as self-regulation, set-maintenance, selective inhibition, cognitive flexibility and efficient planning. These functions are vital to human autonomy, for these abilities enable a person to engage successfully in independent, purposive and goal-directed behaviour. There is a vast amount of multi-factorial EF-assessment tools, displaying low intercorrelations or having a low validity index. Often, the instrument has been developed in a clinical population and its item content does not apply to healthy adults while tapping the extreme (pathological) ends of behaviour.**

In the present study, usefulness and psychometric properties of the Executive Function Index (EFI; Spinella, 1995) were examined. The EFI is a 27-item self-report measure sampling a wide array of behavioural consequences in healthy individuals with five subscales: Motivational Drive, Organization, Impulse Control, Empathy, and Strategic Planning.

**Results**

Results lend support for the use of the EFI as a reliable self-report for EF in both clinical and non-clinical populations.

It is concluded that a person’s perception of the effects of executive dysfunctioning on daily life is a major determinant of the perceived quality of life. We therefore need instruments that consider the consequences of maladaptive executive functioning in both healthy and psychiatric populations. Beliefs about maladaptive and dysfunctional behaviour can only exist in the context of beliefs about healthy, effective and efficient behaviour.

ONIOMANIA OR COMPULSIVE BUYING: AN OVERVIEW

INSTITUTIONS
1. Vincent van Gogh Institute for Psychiatry, Department of Clinical Research, Venray, The Netherlands
2. Radboud University Nijmegen, Behavioural Science Institute / Clinical Psychology, Nijmegen, The Netherlands

AUTHORS
1. Jacques A.J. Boermans1, MD, jboermans@ggznml.nl
2. Jos I.M. Egger1,2, Dr., PhD, j.egger@psych.ru.nl
3. Willem M.A. Verhoeven1, prof. Dr., MD, PhD, wverhoeven@vvgi.nl

Aims/Objectives
Compulsive buyers experience a permanent drive to buy, even when confronted with considerable financial shortcomings or other environmental restrictions.
Scientific interest for compulsive buying dates back on 1910, when Kraepelin and Bleuler spoke of “oniomania.” Few studies are conducted since then, and in mental health settings, little attention is paid to the intertwining of compulsive buying with several mental disorders.

Methods
By means of a Medline, Pubmed, and PsychInfo literature review (1966 - April 2007) with keywords “oniomania”, “buying”, “shopping”, “consumption”, and “compulsive”, “pathological”, “impulsive”, and “uncontrolled”, all articles on symptoms and characteristics, treatment, etiology, and epidemiology were selected. In order to maximize probability of finding useful articles, cited references were tracked, and authors on compulsive buying assessment instruments were contacted.

Results
Epidemiological data is being presented, as well as psychopathological and etiological findings.

Conclusion
There is scarce literature on compulsive buying, most of it stemming from consumer research. Nonetheless, it becomes clear that problematic buying behaviour can cause serious dysfunctions and marked distress in patients, without them being able to stop it. It should therefore be considered as an example of inhibitory related psychopathology. Systematic research is needed to design adequate diagnostic and treatment methods. For that reason, a contextual, neurobehavioural research agenda is presented [1,2].

RORSCHACH TEST, THE TOOL TO ACHIEVE AN INTEGRAL DIAGNOSIS OF PERSONALITY. ITS UTILITY IN WORK PSYCHOLOGY

INSTITUTIONS
1. Delegation of Health, Judicial, Mar del Plata, Argentina

AUTHORS
1. Adriana E Vitali1, Psychologist, Licentiate, adriavitali@hotmail.com.ar

In our area of work is presented cases with different and even contradictory psychiatric diagnosis, generally based on the DSM-IV-clinicelective. This determines the need to arrive at a unifying diagnosis, which can distinguish levels in the functioning of the personality, variables stable or structural basis of the personality; from situational variables, which also may relate to actual situational stress.

The Rorschach offers that possibility, being a qualitative method that combines the quantitative, complements and supports the diagnosis.

The research was based on a significant sample in the context of a broad casuistry. With quantifiable data analyzed how Rorschach allowed to discriminate psychiatric tables with greater accuracy and depth. It analyzes the responses to spontaneous ink stains on standardized sample local and universal, which are correlated with the level and type of intelligence, reasoning, operations and organizational psychology, personality styles, modality in the management of emotions, social skills, psychological defense mechanisms, etc.

Conclusion:
In this way we arrive at knowledge of the structure of the deepest personality, largely inaccessible by other means of assessment which allows among other things, for example, deduce how it will behave at work; simulation can be detected, notable difference concerning questionnaires.

This methodology has been established that it is an efficient tool to validate and integrate psychodiagnosis.

Background Individuals with antisocial personality disorder (ASPD) are more impulsive and show impairment in reinforcement processing. There is increasing evidence for a neurobiological basis of ASPD.

Aims To investigate brain activations associated with behavioural inhibition and reward in ASPD and the effect serotonergic (5-HT) manipulation has on these activations.

Method 25 participants with ASPD and 32 control subjects were randomly allocated to receive the 5-HT2C-agonist mCPP or placebo. Participants were scanned using functional magnetic resonance imaging (fMRI) during a behavioural inhibition (Go/No-Go) and a reward task.

Results In the Go/No-Go task the ASPD group showed reduced task related activations in the orbitofrontal (oFC) and dorsolateral prefrontal cortex (dlpFC) compared to the healthy control group. During reward processing, group comparisons revealed decreased signal in oFC, rostral anterior cingulate (ACC), striatum and hypothalamus in the ASPD group. mCPP increased prefrontal activations in the ASPD group in the Go/No-Go task and in the reward circuit during reward processing.

Conclusions These findings support the notion of differences between antisocial and healthy individuals in brain processing related to behavioural inhibition and reward and their serotonergic modulation. This supports the proposal that targeting serotonin systems may be therapeutic in ASPD.

In a globalized world, multi-culturalism produces cultural differences within a single place in the cities of industrialized nations. The subjects have to be in permanent movement. Our own consulting rooms and clinics are still in the same place, but our tasks of perception, diagnosis and therapy have become much more complex as we are faced with patients from all over the world. This leads to a growing necessity for mental health professionals to broaden their horizon and knowledge. There is a need to experiment with new forms of therapeutic practice and theory, and to develop transcultural competence in the field of mental health.

Five years ago, the Interdisciplinary Center for Intercultural Psychiatry, Psychotherapy and Supervision (ZIPP) was founded at Charité Campus Mitte, University Medicine Berlin in order to be able to deal with the complexity of intercultural work and transcultural research, and to develop transcultural psychiatric and psychotherapeutic approaches. Interdisciplinary collaborations between psychologists, medical and cultural anthropologists, and psychiatrists reflect the interactions of subject and culture. The Center’s work has resulted in a basic curriculum of transcultural psychiatry and psychotherapy. A textbook by international authors has been published in September 2006 (Transkulturelle Psychiatrie und Psychotherapie. Interdisziplinäre Theorie und Praxis. Eds.: Wohlfart/ Zaumseil, Springer Medizin- Verlag, Heidelberg; language: German).

The poster offers an insight into the Center’s structure, its research and its transcultural psychiatric and psychotherapeutic practice.

2. Ioannis Diakogiannis
3. Apostolos Iacovides
4. Ioannis Giouzepas
5. Konstantinos Fokas
6. Georgios Kaprinis

Aims: To investigate the prevalence of comorbidity, distinguish the characteristics of the dual diagnosis population and discover which factors affect length of stay.

Method: All patients admitted over a 12-month period were given the CAGE questionnaire and that part of the EUROPAI questionnaire dealing with substance use. This was followed by a diagnostic interview to establish the final diagnosis in accordance with the DSM-IV criteria. This study assesses diagnosis, substance used, number of substances, sex, age, years of education, family status, family history, whether committed or not, residence and family history of psychiatric disorder, and distinguishes the characteristics of the dual diagnosis population. Following this, cooperativeness in taking medication, SUD comorbidity, and duration of mental illness in conjunction with average length of stay were evaluated statistically.

Results: A total of 313 patients were assessed. Present substance use disorder was identified in 102 individuals (32.6%). The principal substances involved in addiction or abuse were alcohol, cannabis, benzodiazepines and opioids. Comorbid patients were chiefly young men committed and diagnosed as suffering from Other Psychotic Disorders and Cluster B Personality Disorders. The factors found to affect length of stay in this psychiatric clinic were the length of time they had been mentally ill and cooperation in taking medication.

Conclusions: The chief characteristics of the dual diagnosis population must be taken into account in planning integrated treatment programmes for these patients, so staff will be trained to meet these particular needs. It appears that SUD does not affect length of stay.

TRADITIONAL VALUE OF VIRGINITY AND PREMARITAL SEXUALITY IN TURKEY: A UNIVERSITY STUDENTS CASE

INSTITUTIONS
1. Dicle University Faculty of Medicine, Department of Psychiatry, Diyarbakir, Turkey

AUTHORS
1. Aziz Yasan
2. Altan Eslizoglu
3. Faruk Gurgen

Aim: The social meaning ascribed to virginity in connection with traditional gender roles varies according to the sex in Turkey (1,2). Our objective is to research the prevalence of beliefs regarding the virginity, hymen and their effects on sexuality prior to marriage.

Method: The 609 participants who took part in the study were given a socio-demographic data form, a sexuality data form and an information form which comprised of 11 items that concern the hymen and virginity.

Results: Our findings showed that the rates of masturbation and premarital sex were lower (x^2=338.85, p<0.001 vs x^2=112.52, p<0.001) in women (9.80% and 4.71%) when compared to men (85.31% and 43.50%). We find that premarital sex and masturbation associated with religiosity and sexual orientation. While, in relation to the hymen, 48.6 % agreed with the item 'Intense pain is present at initial sexual intercourse'; 21.8 % were of the opinion that 'Masturbation damages the hymen'. The traditional social structure that incites sexual discrimination still prevails over the sexual attitudes and behaviours of university students in Turkey.

Conclusion: It was further determined that the task assigned to women of protecting their chastity and the concerns relating the reto were quite effective in reducing premarital sexuality among women.

EFFECTIVENESS OF PSYCHODERAMA ON RUMINATION, AGGRESSION AND BENIGN CONTROL OF CLIENTS

INSTITUTIONS
1. Islamic Azad University Arak Branch, Psychology, Arak, Iran (Islamic Republic of)

AUTHORS
1. Mehdi Zarebrahimadi, Dr, PhD, mz_bahramabadi@yahoo.com

The goal of this study was investigation of effectiveness of psychodrama on rumination, aggression and benign control of clients in welfare counseling centers of Tehran city. To do so, 24 volunteer clients were intentionally selected from population of individual who had enrolled for attending group counseling sessions in counseling centers of Tehran welfare agency. They have been randomly divided in two groups (treatment and control group). On a pre and post-test design, the participants assessed by the Emotional Control Questionnaire (1. Roger and Najarian, 1989). The data analyzed by the analysis of Covariance and LSD Posthoc test. Findings revealed that the Psychodrama method were effective on the increase of aggression and benign control and decrease of rumination of clients. The findings prove the goals of psychodrama in control emotions of clients (2. Blatner, 2000).

2. Pavel Theiner, Dr, MD, PhD, ptheiner@fnbrno.cz
3. Slavoj Brichcin, Dr, MD
4. Tomáš Kaspárek, Dr, MD, PhD, kasparek@med.muni.cz

Aims/Objectives: Bupropion has been successfully used in the treatment of sexual dysfunction in non-depressed women. With trazodone, an improvement of sexual functioning has been described in the treatment of sexual dysfunction in non-depressed men. The aim of the study was to evaluate the efficacy of the treatment with trazodone or bupropion in non-depressed women with sexual dysfunction (hypoactive sexual desire disorder and/or orgasm dysfunction).

Method: 12 female subjects were treated with trazodone and 10 with bupropion. Subscales desire/frequency and orgasm/completion of the Changes in Sexual Functioning Questionnaire (CSFQ) were chosen to evaluate the treatment efficacy. The CSFQ score was assessed before treatment and after 4-8 weeks of treatment. The results before and after treatment were compared using Wilcoxon test within both groups, and using Mann-Whitney test between groups.

Results: The mean age was 37.9 (trazodone) and 37.5 (bupropion) years. The mean change in CSFQ subscale desire/frequency was of 2.5 in the trazodone group (p=0.003) and 2.2 in the bupropion group (p=0.018). The score of orgasm subscale reached 3.8 in the trazodone group (p=0.003), 2.3 in the bupropion group (p=0.043). No statistically significant difference was found between the antidepressant in terms of efficacy in the treatment of hypoactive sexual desire or orgasm dysfunction. Conclusion: Both trazodone and bupropion had beneficial effects in non-depressed women with sexual dysfunction, their efficacy was equal.

A COMPARATIVE STUDY OF TRANSFORMATION OF NEEDS OF OFFENDERS DURING IMPRISONMENT

INSTITUTIONS
1. 1st Faculty of Medicine and General Teaching Hospital of Charles University, Psychiatry, Prague, Czech Republic

AUTHORS
1. S. Fischer¹, fischerslavomil@seznam.cz
2. J. Raboch¹
3. I. Žukov¹

This paper presents the results of two research studies which focus on the analyses of specific needs associated with members of a delinquent subculture and the psychological alterations which occur as a result of adaptation to their imprisonment. In the first case, the specificity and differences in the area of needs were determined by content analysis of prison correspondence and further by means of an content analysis of association as reactions to a complex of incomplete sentences. The differences have been ascertained by virtue of factors that are considered significant from the point of view of delinquency and potential recidivism. A great deal of attention is focused on prisonisation as a specific adaptation to imprisonment and its influence on the dissimilarity in the structure of the needs of those prisoners investigated. The results of both investigations facilitate mutual comparison. They also partially refer to the discriminating capability of the applied methods. The findings and results are applicable in penitentiary practice and are significant for the practical application by psychologists and other specialists in their work with offenders.

Key words: delinquency, imprisonment, needs, prisonisation, content analysis, projective methods

4. Padurariu Manuela2, Mrs., student

Background
The most widely used animal models of Parkinson’s disease involve intracranial infusion of the neurotoxin 6-hydroxydopamine (6-OHDA) directly into the ascending dopaminergic forebrain bundle, thereby, inducing severe dopaminergic neuronal degeneration associated with profound deficits in learning functions.

The aim of the present work was to study the effects of right-unilateral 6-OHDA lesions of the ventral tegmental area (VTA) or substantia nigra pars reticulata (SNr) on learning and memory processes evidenced by means of Y-maze task and shuttle-box task, respectively. We also examined the effect of nicotine treatment on the 6-OHDA lesioned rats.

Materials and methods
Male Wistar rats were subjected to right-unilateral 6-hydroxydopamine (6-OHDA) lesion of the ventral tegmental area or substantia nigra pars reticulata, or were sham lesioned, and nicotine treatment and their ability to acquire the operant task was studied by means of Y-maze task and shuttle-box task, respectively. Learning and memory tests were began 2 weeks after the operation.

Results
Lesions of both the VTA and SNr resulted in an impairment of both conditioned avoidance response and crossing latency tested by means of shuttle-box task, suggesting significant effects of long-term memory. 6-OHDA significantly decreased spontaneous alternation in Y-maze task, suggesting effects on spatial memory, especially on short-term memory. A low dose of nicotine, a specific nicotinic acetylcholine receptors agonist, administrated 4 consecutively days attenuated the impairment of learning and memory processes in 6-OHDA lesioned rats.

Conclusions
These data suggest that VTA, SNr and nAChRs have a facilitator role in learning and memory processes.

4. Vanesa S Reuter5, Mrs., M.S., 5. Gloria Araujo4, Dr., Ph.D., 6. Marco A Brasil1, Dr., Ph.D., 7. Antonio L Costa2, Dr., Ph.D.
8. Fabiola A Reis5, Dr., Ph.D., 9. Mario Vaisman2, Dr, Ph.D.

Objective: Study the effect of the levothyroxine (LT4) treatment on neuropsychiatric functions of sub clinical hypothyroidism (SH) patients.

Methodology: Outpatients from a clinical sample from the same hospital environment were screened for SH and enrolled in a double-blind clinical trial to receive levothyroxine or placebo for one year. Psychopathological symptoms were based on the scales of Hamilton for anxiety and depression (HAM-A and HAM-D), and Beck’s Depression Inventory (BDI). The participants also underwent the Buschke’s Selective Reminding Procedure, Rey-Osterrith Complex Figure Test, Warrington’s Recognition Memory Test for Words and Faces, and the Wechsler Adult Intelligence Scale neuropsychological assessments.

Results: HAM-D scores reduced in both groups (levothyroxine and placebo) with borderline statistical significance for levothyroxine replacement (p=0.08). A significant improvement occurred in the levothyroxine group for Buschke’s tests for storage, retrieval and consistent long-term retrieval (p=0.004, p=0.025 and p=0.016 respectively). In the placebo group there was a significant improvement only for Buschke’s Storage Test (p=0.042). Warrington’s Test for Words and Faces showed a significantly different average between groups (p=0.041) and was considered an isolated result.

Conclusion: Treatment with levothyroxine caused no significant neuropsychiatric change in the studied group, despite a trend to reduce depressive symptoms.

4. L. Tučková
5. A. Pekáriková
6. H. Tlaskalová-Hogenová

Aims/Objective: Gluten sensitive enteropathy, celiac disease (CD), is induced in genetically susceptible individuals by ingestion of dietary wheat gluten. Incidence of this chronic disease is known (1:200) but the data concerning the occurrence of CD in population of psychiatric patients is still missing. We screened coincidence of CD with some psychiatric diseases according to serological markers of CD.

Methods: Hence, we tested serological markers of CD - IgA Ab against gliadin (alcohol soluble part of gluten) and tissue transglutaminase (tTG) in psychiatric patients (n=50) suffering from psychotic disorder (n=33), bipolar affective disorder (n=12), and depressive disorder (n=5) from blood sample 10 ml. IgA anti-gliadin Ab was detected by ELISA using ethanol soluble fraction of wheat gluten (Sigma, Germany) as an antigen. The testing of IgA anti-tTG Ab was performed by commercial available ELISA (Biosystems, UK) test using human recombinant tTG. Healthy controls - blood donors without positive markers for infection, autoimmune disorders or liver disease were tested for the presence of antigliadin, and anti-tissue transglutaminase (tTG) Ab.

Results: Tested sera of psychiatric patients were all significantly negative for Ab to gliadin and tTG.

Conclusions: We found negative Ab against gliadin and tTG in our group of psychiatric patients. This finding needs further study.

This project was supported by grants VZ MSM 0021620849 and IGA MZ Cr nr/8805-4.

FAMILY ACCEPTANCE OF ITS MENTALLY ILL MEMBER AND NEEDS THAT ARISE

INSTITUTIONS
1. PSYCHIATRIC HOSPITAL OF PETRA OLYMPUS, GREECE, COMMUNITY MENTAL HEALTH CENTRE, KATERINI, Greece

AUTHORS
1. Nota Voura, PSYCHOLOGIST, apnota@hol.gr
2. Dimitris Xilas, PSYCHIATRIST, info@kepsykat.gr
3. Konstantinos Papanikolaou, PSYCHIATRIST, apnota@hol.gr
4. Giorgos Angelidis, PSYCHIATRIST, info@kepsykat.gr

Introduction: One on four people, who are affected by mental illness, face discrimination, isolation and rejection even from their family, till the point of acceptance of the mental disorder. Once they accept the illness, families play an important role in supporting their mentally ill members. The aim of this study is to demonstrate the issue of the difficulties in accepting the mental illness of a family member as well as the needs of the family that bear the burden of caring him/her.

Method: The study is a qualitative descriptive design. It is based on structured interviews with the relatives of 20 psychiatric patients treated at the Community Mental Health Centre (CMHC) in Katerini and at the acute ward of the Psychiatric Hospital of Petra Olympus (PHPO).

Results: Through the analysis of the interview data was possible to conclude that both fathers and mothers have difficulty in accepting the mental disorder that their offspring may suffer from. Sons/daughters seem to accept their parent's mental disorder more easily. People seeking treatment from the CMHC appear to be more acceptable, whereas family members having their relative hospitalised in the acute ward of the PHPO show greater disappointment, guilt, shock, fear and rejection. Upon accepting the situation a variety of needs for family support arise.

Conclusion: Many people are misinformed about mental illness and respond negatively when confronted with a relative's mental illness. Families may reduce this burden when they come to understand mental disorders, perceptions of care and knowledge of coping strategies.

IMPACT OF A PSYCHIATRIC HOSPITAL’S TRANSFORMATION ON STAFF’S PERCEIVED HEALTH AND STRESS LEVELS

INSTITUTIONS
1. Psychiatric Hospital of Petra Olympus, Katerini, Greece
2. Aristotle University of Thessaloniki, Psychology Department, Thessaloniki, Greece

AUTHORS
1. Georgios D Giaglis1,2, Dr, MD, PhD, giaglis@med.auth.gr
2. Konstantina Mantziava2, Mrs, BSc, MSc, kmantzia@hotmail.com
3. Georgios F Angelidis1, Dr, MD, PhD, info@kepsykat.gr

Objective: The study of perceived somatic or mental health and stress levels of the staff in a public Psychiatric Hospital in Greece that has been transformed into a network of community-based psychiatric facilities. Material and methods: The working staff anonymously completed, two years before and two years after the transformation of their hospital, a questionnaire for self-reported stress- and health-levels and number of visits to medical care practitioners.

Results: Stress levels reported were high, especially regarding financial matters as opposed to personal affairs. Women were more stressed in general, and specifically regarding family or work issues, and their perceived level of mental and physical health was much worse than men’s. Nevertheless, the deinstitutionalization of their hospital didn’t affect significantly any of the previous measures. After the transformation, 58.6% of the staff admitted having visited a physician one or more times during the previous semester, in comparison to the 41.5% before (χ²(1)=9.75, p=0.001, U=13342, p=0.004), while men had a bigger admission rate into inpatient hospital clinics (men/women: 17.2%/3.4% after, in contrast to 5.9%/8.8% before the transformation). Finally, age or years in service did not significantly affect the measured variables.

Conclusions: The deinstitutionalization of a Psychiatric Hospital does not seem to have affected stress- or perceived health-levels of the staff. The increased number of visits to physicians and men’s admissions to hospital could be interpreted either as a dissociation between subjective and objective measures of health or as improved use of the available health care.

6. Miltos Livaditis2, PSYCHIATRIST, PhD, vpadap@med.duth.gr

Introduction: Structural clinical interviews have been developed and used to improve the validity and the reliability of the psychiatric diagnoses. The purpose of the study is to standardize the M.I.N.I.-Plus (Mini International Neuropsychiatric Interview) in Greek population.

Method: In this study, 180 participants were evaluated in the local General Hospital, the Mental Health Community Center in Katerini, the Health Center of Eginio, as well as in the acute ward and the Rehabilitation units of the Psychiatric Hospital of Petra Olympus. M.I.N.I.-Plus Interviews and Structured Clinical Interview for DSM-III-R (SCID) were both given to the sum of the participants (in a time range of 5 days). Testing the reliability, 80 participants were being retested by different interviewers. They were assessed as to the following diagnoses according to DSM-IV/ICD-10: Major Depressive Disorders, Dysthymia, Suicidality, (Hypo) Mania, Anxiety Disorders, Alcohol Abuse and Dependence, Non-alcohol Psychoactive Substance Use Disorders, Psychotic Disorders, Anorexia, Bulimia, Anti-social Disorder, Somatoform Disorders, Pain Disorders, Adjustment Disorders, Premenstrual Dysphoric Disorder.

Results: The preliminary results (130 interviews) show high correlation between the diagnostic results of the two Structured Clinical Interviews (about 94%) and high correlation between the test-retest results (about 97%). The understanding and acceptance of the interview by the participants were satisfactory and few explanatory comments were given by the interviewers.

Conclusion: The Greek version of the M.I.N.I.-Plus shows a high validity and reliability in the diagnostic categories where it has been used in this present study and is proved to be a useful diagnostic tool.

Alcohol abuse is probably one of the factors for cellular iron homeostasis. The soluble transferrin receptor (sTfR) has been introduced as a sensitive, early and highly quantitative new marker of iron depletion. Measurement of sTfR in serum has recently emerged as a tool for detecting iron deficiency and that caused by chronic disease [1,2,3].

The aim of the present study was to evaluate the plasma sTfR levels in patients with alcohol dependence, Material and methods: sTfR and serum alanine aminotransferase (ALT), aspartate aminotransferase (AST) were investigated during this study. 34 women treated in Short Term Therapy and Detoxification Ward were studied.

Results: Women with serum sTfR concentrations significantly higher was a significant older (43,18±6,9 vs 37,09±8,3 p=0,043) and have significant increased hemoglobin levels (12,18±8,6 vs 13,92±8,6 p=0,013) than women with normal serum sTfR concentrations. There was no differences of GGTP, AST, ALT CDT Activity in alcohol dependent women with high and normal level of sTfR.

Conclusions: These results suggest that prolonged alcohol abuse as chronic disease can disrupt cellular iron homeostasis and lead to iron deficiency.

Alcohol is the most important cause of liver disease and development of liver fibrosis. The pathological features of hepatic cirrhosis induced by ethanol and by other factors are the similar. It enables an assessment of dynamics of this process using some factors derived from extracellular matrix (ECM) or its metabolites in the serum of blood. Matrix metalloproteinase (MMP9) is endopeptidase that degrade extracellular matrix proteins[1,2,3]. High-sensitivity C-reactive protein increasing when inflammation is present.

The aim of this study was an assessment of MMP9 in serum of alcohol dependent women.

The aim of this study was an assessment of MMP9 in serum of alcohol dependent women.

Study group consists of 40 alcohol dependent women treated in Inpatient Clinic in Torun. The concentration of MMP9 was assessed using immunosassay technique using Human MMP9 Immunoray Quantikine R7D Systems; High-sensitivity C-reactive protein (hsCRP) using immunofluorescence BN2.

Results: Study group with higher hsCRP (>5mg/l) had statistically significant higher MMP9 level compared to women with lower hsCRP (9,66±4,75 vs 6,20±3,08; p=0,049)

Conclusions: There was statistically significant higher concentration of MMP9 in alcohol dependent women with higher levels hsCRP. Our results suggests that prolonged alcohol abuse as chronic disease can be a factor of inflammation and can disrupt regulation of MMP activity and lead to hepatic disorders.

Introduction: Depression has been shown to be more common in Parkinson's disease (PD) than in other chronic and disabling disorders. The most common manifestation of psychosis in Parkinson's disease is visual hallucinations.

Method: 32 patients with idiopathic PD underwent psychiatric, neurological and brain imaging (CT or MRI) evaluation. Psychiatric diagnosis was performed by semistructured interview according with ICD-X criteria and the severity of symptoms was rated with clinical rating scales (Hamilton Rating Scale for Depression; Baylor PD Hallucination Questionnaire). Also all patients were evaluated using the Unified Parkinson’s Disease Rating Scale.

Results: Depressive symptoms were present in more than half of the patients - 59.4% (n=19). 25% of the patients (n=8) had visual and figurative hallucinations. Depression appears to be associated with increased disability and reduced quality of life. Visual hallucinations were significantly associated with higher depression score and worse disease severity. Hallucinations were not associated with history of psychiatric disease.

Conclusion: Previous studies suggest a neurobiological basis for most psychiatric symptoms, although psychological factors are probably involved in the development of affective disorders. Visual hallucinations most probably result from the combined effect on dopaminergic and serotonergic systems in the CNS.

Keywords: PD, depression, visual hallucinations

The metabolic syndrome (MS) is a cluster of interrelated common clinical disorders, including obesity, glucose intolerance, hypertension, insulin resistance and dyslipidemia. The syndrome is associated with greater risk of atherosclerotic disease and consequences than any of its individual components. The role of insulin signaling pathway disruption in the pathogenesis of MS is unquestioned. The phosphatidylinositol-dependent serine-threonine protein kinase AKT has been proposed to be a canonical intermediated in the insulin signaling pathway. Atypical antipsychotics are prescribed class of drugs for schizophrenia. Although the use of atypical antipsychotics offers many benefits, like lower risk of extrapyramidal symptoms, than typical antipsychotics, these drugs appear to be associated with varying degrees of MS. Despite a greater understanding of the binding profile of these drugs recently, the pharmacological mechanism underling their side effects remain unclear. We investigated the relationship between antipsychotic treatment and modulation of insulin pathway downstream target AKT. To characterize that, we adopted the nematode Caenorhabditis elegans, a genetic flexible neuroscience model that has orthologs systems for dopamine, serotonin and other neurotransmitters. We examine the potential contribution of different antipsychotics treatment on C. elegans AKT phosphorylation through western blot analyses. The results demonstrated treatment reduced on threonin-308 phosphorylation. Our study revealed a tuning of insulin pathway target AKT by atypical antipsychotics in C. elegans and shed light on mechanism of MS during atypical antipsychotics treatment.

NEUROLOGICAL SOFT SIGNS AND THEIR RELATIONSHIP TO ONE-YEAR OUTCOME IN FIRST-EPISODE SCHIZOPHRENIA

INSTITUTIONS
1. Medical Faculty, Masaryk University and Faculty Hospital Brno, Department of Psychiatry, Brno, Czech Republic

AUTHORS
1. Richard Bártaček¹, Dr., MD, rbartacek@gmail.com
2. Radovan Přikryl¹, Dr., MD, PhD, radovan.prikryl@post.cz
3. Libor Ustrohal¹, Dr., MD, PhD
4. Eva Češková¹, Prof., MD, CSc.

Neurological soft signs (NSS) are considered to be one of the biological markers of schizophrenia. There are four categories of soft signs: sensory integration, motor coordination, sequencing of motor acts, and “others”, including primitive developmental reflexes. Neurological soft signs are possibly associated with impaired integration between sensory and motor systems.

The aim of this study was to examine the relationship between the severity of neurological soft signs in patients with schizophrenia, and to investigate stability of neurological soft signs within one year from onset of the first episode of schizophrenia.

The study included 92 first-episode male schizophrenic patients. Neurological soft signs were assessed during index hospitalization and at a one-year follow-up. NES (Neurological Evaluation Scale) was used as the assessment tool. Two groups of patients were formed according to their psychiatric status assessed using PANSS (Positive and Negative syndrome Scale): remitters and non-remitters.

There was significantly lower score in the non-remitters group for the NES item “other” at baselines as well as significantly higher overall severity of NSS at the one-year follow up. At one-year follow up significant reduction of the overall NES score was found in remitters group.

The association between neurological soft signs, treatment response and outcome may characterize a subgroup of patients with poor course of illness and outcome. Neurological soft signs may be therefore regarded as one of the indicator of treatment response in patients with first episode of schizophrenia.

POSTTRAUMATIC STRESS AND PERSONAL RESOURCES AMONG UPROOTED ISRAELIS

INSTITUTIONS
1. University of Haifa, School of Social Work, Haifa, Israel

AUTHORS
1. Hasida Ben-Zur³, Associate professor, PhD, zbz@netvision.net.il
2. Ora Gilbar³, Professor, PhD, Gilbar@research.haifa.ac.il

Purpose: This prospective study aimed to assess personal resources as predictors of posttraumatic stress in uprooted Israeli citizens following Israel’s disengagement from the Gaza Strip and northern Samaria in the summer of 2005.

Methods: A telephone interview was conducted with 104 respondents several weeks before the forced uprooting (T1), several weeks afterward (T2), and 9 months later (T3). At T1 the respondents answered a questionnaire which included assessments of their personality characteristics (mastery and optimism), educational levels, and religiosity. At all three time points they assessed their anxiety and hostility as related to the national political/security situation. At T3 they were also questioned about posttraumatic symptoms and living conditions.

Results: At T3, nine months following the uprooting, only 12.5% of the 104 uprooted respondents had found a permanent home and only 54.3% had found a permanent job. Nation-related anxiety and hostility were at lower levels at T3 than at T1. Higher levels of a combined measure of mastery-optimism, higher education levels, being secular, and lower levels of anxiety at T1, predicted lower posttraumatic stress at T3.

Conclusions: The findings underscore the importance of personal resources such as mastery-optimism and education in coping with the traumatic event of forced uprooting.

Key words: posttraumatic stress, uprooting, personal resources

STUDY OF THE COHERENCY INTER AND INTRAHEMISPHERIC IN THE FRONTOTEMPORAL LOBES AFTER A PERIOD OF HYPERVENTILATION IN PATIENTS WITH MENTAL ILLNESS.

INSTITUTIONS
1. Central University of Venezuela, Department of Psychiatry, Caracas, Venezuela

AUTHORS
1. Monica Bifano1, Dr, MD, bifanom@yahoo.com
2. Julio Campos1, Dr., MD, juliocamposm@cantv.net

Introduction: The electroencephalogram is a useful tool in studying patients with mental illness; this method is non invasive, reliable, reproducible and cheap. The qualitative interpretation allows us the diagnostic differentiation with other morbid processes and the quantitative results approach us to the comprehension of the cerebral function. The coherency analysis determines the symmetry of the signal and reflects the degree of neural interconnection.

Objective: This study describes the coherency values before and after the application of a stimulus in patients with mental illness and the utility in the daily clinical practice.

Methods: 67 patients were referred to the laboratory and classified according to the DMS IV TR criteria, an electroencephalogram recording was performed with the coherency analysis inter and intrahemispheric before and after the application of a maneuver of hyperventilation.

Results: The interhemispheric coherency was observed to be less after the hyperventilation maneuver in all groups of patients, increasing at higher frequencies with the exception of the esquizophrenic patients. It was observed a tendency of a greater coherency right intrahemispheric being significant in the depressive patients.

Conclusions: The coherency analysis is useful in the comprehension of the cerebral function, it represents the degree of neural interconnection and it was seen in psychiatry patients that the signal is more random than lineal posterior to the stimulus

ANALOGIES BETWEEN CANCER AND SCHIZOPHRENIA

INSTITUTIONS
1. CENTRO DE INVESTIGACIÓN, DIFUSION Y PROMOCION DE LA LIBERTAD INTERIOR (CIPLI), Bahamas

AUTHORS
1. Olivo Blanco1, DR., PHD

Objective: Demonstrate that both pathologies possess a same origin.

Method: Analysis and record of those consciousness states produced in the real I search, during 3 decades.

Results: The galloping multiplication of atypical cells becoming unrecognizably to the organ and, these, originating cytologic disorders where they are spread; an uncontrolled proliferation of abnormal ideas, returning unknown to the Being and, this one, causing chaos where it stops. The physiological disconnection among cells producing abnormal tissue, useless for the organism; the logical unconnection among ideas engendering anomalous ideations, useless for individual. Incompetence to stop pathological cells growth; inaptitude to stop the development of a morbid personality. Incapacity to: stop the parasitic progress of a ‘foreign body’ (atypical cells), correct the energetic corporal disorder and avoid the guest emaciation; impotence to: brake the parasitic advance of the ghostly ‘foreign body’ represented by the materialization of that sickly ideation, to amend the internal energetic chaos and stop the depauperization as guest. Regression to cellular undifferentiation and retrogression to primitive forms of behavior are some of the similitud among them.

Conclusion: Such analogies, are product of those learned conditioned reflexes that reach to invert the direction of the internal metabolic Energy.

Objective: To study the effect of stress-management psychotherapy in inflammatory bowel diseases (Ulcerative colitis (UC) and Crohn’s disease (CD)).

Materials and Methods: Fifty-nine patients with Ulcerative Colitis (UC) and 55 patients with Crohn’s disease were included, age ranging from 18-60 years, with a relapse/continuous disease activity previous 18 months, a simple (CD) or clinical (UC) disease activity score >4, a perceived stress Questionnaire (psQ) score ≥60 and without serious mental diseases or other serious medical conditions, were randomized to treatment as usual (TAU) or TAU+ stress-management psychotherapy consisting of 3 group sessions (psycho-education, problem-solving, relaxation) and 6-9 individual sessions based on cognitive behavior methods, and one to three individual booster sessions at the 6 and 12 months follow-up assessments. The patients were assessed by gastroenterologists blinded to intervention-group at baseline, 3, 6, and 12 months, and at the end of study at 18 months.

Results: Mixed linear models in separate analyses of UC and CD were performed. There was not any effect of the intervention in either UC or CD. However, there was a time effect and an interaction effect (time×intervention-group) at the 3, 6 and 12 months assessments in UC, giving the intervention-group higher disease activity at these time-points. Baseline disease activity was a predictor of disease course in CD, but not UC patients.

Conclusion: The intervention had no overall effect on the disease course in neither UC nor CD. However, in UC the results indicated that the intervention might worsen the disease course temporarily.

Although there is evidence for attentional dysfunction in children with attention deficit hyperactivity disorder (ADHD), the neural mechanisms of these deficits remains poorly understood. Recent research in attention has involved three networks of anatomical areas that carry out the functions of orienting, alerting and executive control (including conflict monitoring). Studies of ADHD children using tasks somewhat similar to the Attention Network Test (ANT) have shown some evidence of abnormalities in alerting and/or conflict. The objective of the present study was to investigate these three particular aspects of attention in children with ADHD. Twenty-five medication-naïve boys with ADHD and 25 healthy controls, aged 8 to 12 years, were studied. A child-friendly version of the ANT was used to measure the efficiency of the three networks. The test is a version of the flanker task with alerting and orienting cues. Three subtractions were computed to obtain the alerting, orienting and conflict score for each participant.

Across all trials, children with ADHD showed significantly longer reaction times (RTs) and made more errors than healthy controls. Children with ADHD had a significant impairment in their conflict system. Children with ADHD showed a numerically but not significantly larger alerting and orienting effect.

This study suggested that the dysfunction in executive control system is the strongest deficits in children with ADHD. These findings support the notion that ADHD patients have a specific attentional deficit, rather than a global one.

3. Dubravka Salcic1,2, Mrs., PhD MD, ctvmost1@bih.net.ba

Objective: To determine the efficacy of sertraline in the treatment of chronic psychological consequences with torture survivors.

Methods: The sample consisted of 40 patients with symptoms of chronic Post Traumatic Stress Disorder. All subjects received treatment with sertraline in therapeutic dose range in the period of six months. All subjects were assessed prior to treatment and in 3 month-follow-up and 6 months follow-up using of following instruments: Mississippi Questionnaire for PTSD, The Clinical Global Impressions scale (CGI), and the Hamilton Depression rating scale (HAM-D-21).

Results: The difference between three assessments with Mississippi Questionnaire for PTSD was statistically significant. PTSD rate in our sample was reduced from 100% prior to treatment to 40% subsequent to treatment with sertraline. The results indicate statistically significant reduction of depression on the Hamilton Depression rating scale (HAM-D-21), following six months treatment with sertraline. Sertraline was administered in daily dosis of 50 mg in 80% of the subjects, and in the daily dosis of 100 mg in the remaining 20% of the subjects. Unwanted effects were registered in four of the subjects and they were of mild intensity.

Conclusions: Sertraline proved to be very efficient and well tolerated in the treatment of chronic psychological consequences with torture survivors in this study.

3. John Norrie3, Mr

Self-report assessment scales are used in psychiatry, however use in psychoses has been limited given concerns regarding impact on assessments of positive symptoms, cognitive impairment and reduced insight. We report on successfully utilising the Avon Mental Health Measure (Avon)1 a self-report needs assessment. The Scottish Schizophrenia Outcomes Study (SSOS)2 is a longitudinal, naturalistic cohort design of 1015 participants with multi-episode ICD10 schizophrenia (F20-25). Data collection: sample demographics, medication, psychosocial interventions, services utilised, pragmatic outcomes (hospitalisation, detention, self-harm etc), clinical outcomes (HaNOS) and patient self assessments (Avon) collected at baseline, and annually over 3 years. Data analysed using Logistical modelling. Demographic characteristics are described; 77% retention in Phase 3; All three indices of outcome (clinical, pragmatic, self-reported) showed positive trends. Avon scores improved steadily throughout the study, in line with pragmatic outcomes, while improvements in clinician assessed outcomes were more modest. Polypharmacy was common with only 30% on one psychotropic and 14% on >4; throughout the study the use of clozapine, mood stabilisers and antidepressants increased. In a large, representative sample of participants with schizophrenia it was feasible and useful to collect patient self assessment data within a naturalistic design. It is possible to incorporate patient led self assessments of need into routine practice in chronic conditions such as schizophrenia. This not only provides useful data for clinicians but may improve engagement with treatment.

2. Jaider a. Barros-Bermúdez², Dr., MD, jbarros@unab.edu.co
3. German E. Rueda-Jaimes³, Dr., MD, gredu@unab.edu.co

Objective: To compare the psychometric properties of the two versions of Cigarette Dependence Scale, 12- and 5-items (CDS-12 and CDS-5) (1) in adult smokers from the general population of Bucaramanga, Colombia.

Method: One-hundred twenty-six current adult smokers completed the CDS-12. They were aged between 18 and 65 years (mean=38.0; DE=13.6) and mean scholarship was 7.7 years (SD=4.0). Cronbach alpha, sensitivity, specificity, predictive values, likelihood values, Cohen kappa, and ROC area were calculated for each version. The Compose International Diagnostic Interview for nicotine dependence applied by a psychiatrist was taken as the gold-standard.

Results: For the CDS-12 (cut-off point = 30), Cronbach alpha was 0.90; sensitivity, 0.77; specificity, 0.71; positive predictive value, 0.90; negative predictive value, 0.47; positive likelihood value, 2.8; negative likelihood value, 0.33; Cohen kappa, 0.40; and ROC area, 0.80.; and for the CDS-5 (cut-off point = 11), Cronbach alpha was 0.75; sensitivity, 0.80; specificity, 0.64; positive predictive value, 0.89; negative predictive value, 0.47; positive likelihood value, 2.2; negative likelihood value, 0.31; Cohen kappa, 0.39; and ROC area, 0.80.

Conclusions: The two versions of CDS exhibit similar psychometric properties among Colombian adult smokers better than the Fagerström nicotine dependence scale. This finding needs to be corroborated in larger populations.

RELIABILITY OF THE WHO-5 WELL-BEING INDEX AMONG
COLOMBIAN ADOLESCENT STUDENTS

INSTITUTIONS
1. Instituto de Investigación del Comportamiento Humano, Dirección de Investigaciones, Bogotá, Colombia
2. Universidad de Cartagena, Facultad de Enfermería, Cartagena, Colombia

AUTHORS
1. Adalberto Campo-Arias¹, Dr., MD, campoarias@comportamientohumano.org
2. Giskar Miranda-Tapia², Mr., gamtsandiego@yahoo.com
3. Zuleima Cogollo², Mrs., MSc, zcogollo@yahoo.com.mx

Objective: To calculate the internal consistency and stability over four weeks of the WHO five-item version of the Well-being Index (WHO-5) (1) among nine-grade adolescent students dwelling in a low-income and high-level of violence neighborhood in Cartagena, Colombia.

Methods: A total of 162 students participated in the first opportunity (Mean age =15.1, sd = 1.1, and 55.6% were boys), and 157 adolescents in the last one (Mean age =15.1, SD = 1.1; and 56.1% were boys). Cronbach alpha coefficient was used to compute internal consistency, and Pearson's correlation (r) and intra-class correlation coefficient were applied to calculate stability over four weeks (test-retest) (2).

Results: The internal consistency of the WHO-5 was 0.66 in the first application; and 0.70, in the second; and test-retest over four weeks showed Pearson r = 0.61 (p<0.0001) and intra-class correlation coefficient, 0.61 (95%CI 0.50-0.70).

Conclusion: The WHO-5 presents an acceptable internal consistency and stability over four-weeks among Colombian students living in a disadvantaged neighborhood. Now, criterion validity studies shall be carried out.

Acknowledgments: This research was supported by the School of Nursing, University of Cartagena, and Human Behavioral Research Institute, Bogotá, Colombia.

Background: The 12 item-General Health Questionnaire (GHQ-12) is the shortest version of GHQ. The questionnaire works as well as the longer instruments and is used more frequently in epidemiological surveys. It is an effective instrument for aging studies because of its brevity and absence of somatic symptoms. Previous studies of Principal Component Analysis (PCA) were carried out in adult populations only, demonstrating two-and three-factor solutions.

Methods: This study involved 392 participants over 75 years old in a population-based survey in Bambui, Brazil. Both PCA and Confirmatory Factor analysis (CFA) were performed. In CFA, several factor structures were compared using different goodness-of-fit indices. (The association between factor scores of the model with the best fit and participant characteristics were analyzed by linear regression)

Results: PCA suggested a three-factor model. Graetz’s three-factor solution (Anxiety Depression, Social Dysfunction and Loss of Confidence) was the best model in CFA according to goodness-of-fit indices. Activity limitation and poor self-reported global health were associated with the anxiety/depression and social dysfunction factors. Cognitive impairment and female gender were associated with social dysfunction. Loss of confidence was not associated with these or other relevant variables.

Conclusion: The three-factor solution proposed by Graetz seems to be the best fit also for people over 75 years old. Further studies are needed to understand the conceptual and practical relevance of these underlying factors, particularly loss of confidence in the elderly population.

Key Words - GHQ-12; Common Mental disorders; elderly; latent trait; Principal component and Confirmatory Factor Analysis

5. Jaroslav Tintera2, ing.

Progress in neuroimaging contributed greatly to the schizophrenia research, including investigation of the etiological factors. We tested the hypothesis that lack of the normal asymmetry of language activation is familial and that it can be found in both schizophrenic and non-schizophrenic family members. In particular, we wanted to know whether relatives who are supposed to be transmitting liability to the illness also demonstrate the loss of asymmetry of language activation. We studied 5 families with at least two members affected with schizophrenia. Functional imaging (fMRI) was used to study cortical activation during a verbal task in Broca’s area and its contralateral homologue in subjects with schizophrenia and their both parents who never manifested any psychotic symptoms but one of them had mother or father with schizophrenia. Schizophrenia patients showed lack of asymmetry of language activation. Parents without schizophrenia among their elderly relatives showed normal asymmetry of language activation. Three of parents who supposedly transmit liability to the illness demonstrated the loss of asymmetry of language activation. Our results suggest that lack of the normal asymmetry of language activation could be one of the inherited etiological factors of schizophrenia.

4. Yuan-Pang Wang, Dr., Md, phd, gnap_inbox@hotmail.com

Objectives: To investigate, in a community sample, the association of suicidal behavior (SB) with comorbidity of alcohol or substance use disorders (AUD/SUD) and any depression (major depressive episode or dysthymia).

Methods: A representative sample (n=1,464) of two boroughs of the city of São Paulo, Brazil, older than 18 years-old was face-to-face interviewed with CIDI to generate DSM-III-R psychiatric diagnosis. First, descriptive statistics depict sociodemographic and main outcome variables (AUD, SUD, depression, and dysthymia). Four logistic regression models tested the psychiatric determinants of SB (thought of death, desire of death, suicide thought, and suicide attempt). Adopting SB as dependent variables, univariate and multivariate logistic regressions were conducted to estimate the influence of outcomes through stepwise backward method.

Results: Being female and in depression or dysthymia were significantly associated with SB. In female with comorbidity dysthymia/AUD and dysthymia/SUD, most part of association with SB was attributed to dysthymia. Similar effects occurred with depression on comorbidity depression/AUD or depression/SUD. It is observed an association between "desire of death" and comorbidity dysthymia/AUD/female (OR=12.6), and dysthymia/SUD/female (OR=13.1). AUD was associated with SB in all four models tested (OR=2.2 to 3.2) and it is observed an increasing gradient of association toward most serious behavior. On the transition between suicide thought and attempt, being female were significantly associated with suicide attempts, even there were no differences on suicide thoughts.

Conclusion: Presence of depression/dysthymia influence SB, independently of presence of AUD/SUD. This suggests the clinical importance of depressive symptoms as predictors of suicidality in patients with AUD/SUD.

The aim of the present study was to investigate the effect of the chronic treatment with paroxetine or alprazolam on c-Fos expression in the periaqueductal grey matter (PAG) of golden hamster in imminent risk of death. Male golden hamsters (n=8), weighing 100-120g, were used. As aversive stimuli, freely moving Brazilian coral snakes (Micrurus frontalis) (n=4), weighing 100-150g were used. Paroxetine (at 20mg/kg), alprazolam (at 4 mg/kg) or physiological saline was intraperitoneally and randomly administered, during 21 days in independent groups. The fear-induced behaviour of rodents was recorded during 15-min inside a polygonal arena. Two hours after the agonistic confront, the rodents were sacrificed and perfused, and the encephalon was studied using immunohistochemistry to detect Fos-positive neurons in the PAG. The confront with the venomous snakes caused a clear panic-like effect in rodents expressed by increased defensive attention, risk assessment, freezing, and escape, followed by Fos expression in different PAG columns. The chronic treatment with paroxetine or alprazolam caused a clear antiaversive/antipanic effect, minimizing aversion-induced behaviours, and there was a decrease in Fos expression in the rostral, medium and caudal divisions of the dorsomedial [F(2,46)=19.02; p<0.05, in all cases], dorsolateral [F(2,59)=20.36; p<0.05, in all cases], and lateral [F(2,61)=15.77; p<0.05, in all cases] PAG columns. These data suggest the involvement of the PAG in the organization of panic-like behaviour and suggest that the dorsomedial, dorsolateral and lateral columns of the periaqueductal grey matter are putative sites of antipanic effect of paroxetine and alprazolam. This work was supported by CNPq, FAPESP and FAEP.

2. Anastasia Titarenko², psylab2006@yandex.ru
3. Irina Tarusina², psylab2006@yandex.ru

Objectives: The schizophrenic patients' families have special features. We supposed that families of patients with schizo-affective psychosis also have special features. The purpose of our research was to compare families of the schizo-affective psychosis patients and patients with schizophrenia.

Methods: In our groups there were 40 patients with schizophrenia, 34 patients with schizo-affective psychoses, 40 people without mental health problems (the control group) (age - 17-40 years old). Patients were tested by Family Assessment Structure Test (Hehring, 1993) and the inventory “The Style of Emotional Communication in the Families” (Kholmogorova, 1998). Both these methods test the patients' representation of their families.

Results: The many characteristics of the schizo-affective psychosis group were in the middle between the group of the patients with schizophrenia and the control group. The patients of both groups described their families as families with high hierarchy. In two groups parents (mostly mothers) were over included to their children's life. Many patients would like to reduce the hierarchy and the over inclusion. In the families of the patients with the schizophrenia there is more distrust to other people than in the families of the patients with the schizo-affective psychosis.

Conclusions: Psychological researchers can make some input to the discussions about the differentiation the schizophrenia and the schizo-affective psychosis. The effective modern treatment of these two groups of patients should include family therapy and have some special features for each.

MARITAL DISTRESS AND GENDER DIFFERENCES

INSTITUTIONS
1. Institute of Mental Health, Serbia and Montenegro

AUTHORS
1. Saveta Draganic-Gajic¹
2. Dusica Lecic-Tosevski¹
3. Milica Pejovic-Milovancevic¹
4. Smiljka Popovic-Deusic¹

Objective: There is considerable literature linking personality, individual psychopathology and marital problems. In this study we analyzed gender-related differences concerning the perception of marital quality and satisfaction during marital distress, as well as the impact of partners' individual psychopathology on marital adjustment.

Methods: The sample of 75 distressed couples was assessed, 39 couples in the process of divorce and 36 couple seeking marital therapy. Personality of the subjects was evaluated using Millon Clinical Multiaxial Inventory (MCMI-III) and the marital adjustment using Dyadic Assessment Scale (DAS). The relationship adjustment of each person was correlated with his/her own self-related personality and partner's self-related personality.

Results: The obtained results concerning marital adjustment were significantly lower in both groups of women, comparing their partner's groups, in all dimensions: consensus, satisfaction, affective expression and cohesion. The significant negative correlation was found between men's anxiety and dysthymia and all dimensions of spouse's marital adjustment scales, as well as with their own marital affective expression.

Conclusion: Our results provide support to the hypothesis concerning gender-related differences in marital distress. The results are discussed in a context of systemic perspective including the role of intrapersonal and interpersonal processes, "partner's effect" in partner's relationship quality and stability, and the importance of specific gender roles in marital relationship.

Background. Both presence and replication activity of the hepatitis C virus in brains of patients with chronic hepatitis C (CHC) were revealed. Significant proportion of CHC patients exhibit cognitive abnormalities. The purpose of this exploratory study was an assessment of the frequency and factors associated with cognitive deficits in CHC patients.

Methods. Adult CHC patients with compensated liver function, without current and past psychotic disorder, bipolar disorder, substance abuse or an organic brain damage were enrolled. Demographic and clinical data were collected from CHC patients and from control healthy subjects. Brief neuropsychological battery consisted of TMT A+B and the Stroop test A+B. Neuropsychological performance was compared within age subgroups (18-29; 30-39; 40-49 and 50-60 years).

Results. 239 CHC patients aged 18-60 years (male/female ratio 119/120) and 170 healthy subjects matched for age and education level were recruited. Patients performed significantly worse on all cognitive measures in every age subgroup. Using cut-off point criterion of >2SD we found that, depending on the measure, between 21% and 34% of CHC patients had substantial cognitive dysfunctions. Neuropsychological performance was negatively correlated with level of education and work status in CHC patients. No correlation was observed between cognitive performance and both staging and grading in liver biopsy in CHC patients.

Conclusions. Significant abnormalities of working memory and executive functions were present in at least 20% CHC patients with compensated liver function within all age clusters. Associations of most of these abnormalities with level of education and work status in CHC patients were found.

4. Roumen V Miley, Dr., MD, PhD, milevr@providencecare.ca
5. Regina du Toit, Dr., MD, dutoitr1@providencecare.ca

Background: Serum brain derived neurotrophic factor (sBDNF) levels were found to be significantly lower in depressed patients than healthy controls and negatively correlated with illness severity. Effective pharmacological treatment has been shown to increase sBDNF concentrations, in depressed patients, to that of healthy controls (1). However, studies of the effect of repetitive Transcranial Magnetic Stimulation (rTMS) on BDNF levels have been limited and conflicting (2).

Objective: To examine the change in sBDNF levels in depressed patients after receiving rTMS and assess its relationship with illness severity.

Method: sBDNF levels were measured pre and post-treatment, 10 rTMS sessions, in patients (n=8) experiencing a major depressive episode. sBDNF levels were determined using a sandwich ELISA. Illness severity was measured using the HDRS and CGI.

Results: sBDNF did not significantly change with treatment (pre-treatment mean±SE: 29.66±5.3 ng/ml, post-treatment mean±SE: 40.55±15.6 ng/ml, p=0.550). A significant decrease in HDRS scores was seen with treatment (pre-treatment mean±SE: 26.1±1.3, post-treatment mean±SE: 14.3±3.1, p=0.0008). Half (4) of the patients had a least a 50% decrease in HDRS score. A strong positive correlation between change in illness severity, HDRS score, and change in sBDNF levels with treatment (R=0.87) was seen.

Conclusion: Our preliminary results suggest that rTMS, in contrast to antidepressant medication, does not affect sBDNF levels. Although rTMS appeared to be an effective antidepressant treatment.

The complexity levels of information processing into the psychic structure can be approached differently. At this point, taking into consideration this point of view, we may distinguish at this point the following levels: biophysical, biochemical, synaptic - neuronal, neuronal circuits, neuronal networks, non-reflected logical circuits, verbalization filter and figurative representation, reflected thinking, inter-individual level of human communication and the noosphere of the socio-cultural group. We develop the psychic model in many previous papers beginning with 1975. We found arguments in J. Piaget's theories of intelligence development, and recently in conceptions of South African anthropologist Tobias regarding to humanization process and in the description of the speech and intelligence development of the children. The filter mechanism is that of operating with the terminal (final) recognition programs of the sensorial systems on subliminal commands sent to the communication effectors. In other words, it is about the projection of several impulses or bio-potentials on the organism’s peripheral side, especially of the motility and sensorial perception systems, with auto - perception on the sensorial ways as interior imaginary sensations. This feedback occurs, generates and grounds itself during the first of human communication, when the children are still thinking loudly and when they hear their own voice, which gradually becomes silent - silent speech. The coupling of the interior (silent) speech with other perception areas, therefore motility, auditory plus image, possible gesture, increases the complexity of the filter and of the auto - control of the reflected thinking. Our model not excludes other models of psychopathology.

2. Maria Luisa Figueira2, Dr., MD, PhD, canessa@mail.telepac.pt
3. Hagop Akiskal3, Dr., MD, hakiskal@UCSD.Edu

The present study was intended to explore the potential relationships between self-esteem and affective temperament (Akiskal et al., 2005) of nurses working for Psychiatric and Mental Health Departments. The ultimate goal is to establish which factor determines their professional stress and adaptation.

METHODS: Self-administered questionnaires were given to 152 nurses employed in three Portuguese public hospitals. The questionnaire items included socio demographic and job-related data and two scales: the Portuguese version of TEMPS-A Scale (Akiskal, 2005) and the Personal Self-esteem Scale (Ribeiro, J.L.P 2006). For statistical analysis besides descriptive statistics, a correlation model was used.

RESULTS: Hyperthimic Temperament was the more prevalent subtype. Women presented a higher Self-esteem positively correlated with Cyclothymic and Anxious temperaments. The results also show that there is a correlation between marital status and Irritable Temperament, and between the years of professional experience and the Cyclothymic and Hyperthymic Temperaments.

CONCLUSION: An interaction between temperament subtypes, self-esteem and professional experience was observed. Gender differences are also significant. Further study is needed to investigate the potential relationship between temperament, self-esteem and professional satisfaction and resilience to job-related stress factors in Psychiatric Departments.

A STANDARDIZED SCORING METHOD FOR THE COPY OF PENTAGONS TEST, DEVELOPED TO BE SUITABLE FOR USE IN PSYCHIATRIC POPULATIONS

INSTITUTIONS
1. Aristotle University of Thessaloniki, 3rd Department of Psychiatry, Thessaloniki, Greece
2. Bakirköy State Teaching and Research Hospital for Neuropsychiatry, 5th Inpatient Department of Psychiatry and Outpatient Unit of Mood Disorders, Istanbul, Turkey

AUTHORS
1. Konstantinos N Fountoulakis¹, Dr., MD, PhD, kfount@med.auth.gr
2. Melina Siamouli¹, Dr., MD, siamel@med.auth.gr
3. Panagiotis Panagiotidis¹, Dr., MD, psypapan@yahoo.gr
4. Stamatia Magiria¹, Dr., MD, routsonis@yahoo.gr
5. Stavroula Sokolaki¹, Dr., MD, sokola@mail.gr

Aim: Although the 'copy of pentagons' test, versions of which are included in the Bender-Gestalt test and the Mini-Mental test, exists for years, little has been done to standardize it in detail. The aim of the current study was to develop a novel and detailed standardized method of administration and scoring.

Material and Methods: The study sample included 93 normal control subjects (53 females and 40 males) aged 35.87±12.62 and 127 patients suffering from schizophrenia (54 females and 73 males) aged 34.07±9.83. The psychometric assessment included the PANSS, the YMRS, and the MADRS.

Results: A scoring method was developed and was based on the frequencies of responses of healthy controls. Chronbach’s alpha and test-retest and inter-rater reliability were very good. Two indices and six subscales of the Standardized Copy of Pentagons Test (SCPT) were eventually developed.

Conclusion: The SCPT seems to be a reliable, valid and sensitive to change instrument for the testing of frontal lobe function based on Luria’s graphic sequence test. The great advantage of this instrument is the fact that it is paper and pencil, easily administered and little time consuming. Further research is necessary to test its usefulness as a neuropsychological test.

PSYCHOTHERAPIES BETWEEN EFFECTIVENESS AND IDEOLOGY

INSTITUTIONS
1. Mental Health Centre "Roseto", A.S.L. Avellino 2, Avellino, Italy

AUTHORS
1. Vincenzo Fricchione Parese¹, Dr., frik-out@tiscali.it

Many social psychiatrists reveal a contemptuous attitude for drugs, whereas they believe that psychotherapy or social interventions are superior or anyway preferable.

But what is the effective value of various psychotherapies?

While drug-placebo differences are increased by illness severity, psychotherapies prove to be less effective as illness severity grows. Besides, although in a way industry sponsorship influences drug study outcomes, on the far side much larger effects are associated with an investigator's allegiance to particular model of psychotherapy. At present exist more than 300 different models of psychotherapies all over the world; the role of ideology prevails in assessing their efficacy, but their validity and cost-effectiveness is insufficient or unclear.

Real difficulties exist in providing meaningful evidence about psychotherapies efficacy: exclusion rates of 40-70% of presenting patients limit their generalisation; critics argue that effect-size of psychotherapies is overestimated because of inappropriate controls; few trials have extended follow-up and those that do show a clear tendency for patients to relapse. Moreover, elements related to individual practitioner and patient seem very influential part of the "active ingredients" but are "non-specific factors" as regards to modality of therapy. In short, a lot of influences or biases that randomised trials normally seek to exclude appear to be essential part of active ingredients of psychotherapy.

Psychotherapy may be in contrast with biomedical psychiatry in its conceptualisation of mental illness, but internecine warfare between cultures of medicine and psychotherapy must stop; psychotherapists need to speak coherently and convincingly in language that others can understand.

COMPARATIVE STUDY OF PATIENTS AND RELATIVES’ CONCEPTS ON HEALTH, MENTAL ILLNESS AND PSYCHIATRIC CARE

INSTITUTIONS
1. Escola de Enfermagem de Ribeirão Preto/USP, Enfermagem Psiquiátrica e Ciências Humanas, Ribeirão Preto, Brazil

AUTHORS
1. Vera Lucia Mendiondo Osinaga¹, Doutor, PhD, wosinaga@terra.com.br
2. Antonia Regina Ferreira Furegato¹, Doutor, PhD, furegato@eerp.usp.br
3. Jair Licio Ferreira Santos¹, Doutor, PhD, jairlfs@fmrp.usp.br

This study aim to compare the opinions of mentally-ill patients and their family members on health, mental illness and psychiatric care.

Methods: The sample consisted of 750 persons who attended 3 psychiatric services (Emergency Unit, Psychosocial Care Center and Regional Mental Health Clinic). Data were collected by 2 instruments: a) a questionnaire to evaluate social-demographic and clinic profile of the subjects. b) a opinion survey scale with 56 assertions on health, illness and psychiatric care to measure the subjects agreement.

Results: Patients with low educational and professional levels (70%), with a lack of knowledge about their disease (1/3); younger population at the Emergency Unit (40% less than 19 years old), and more women as caretakers. More drug treatment is given at the Clinic (76%), low amount of hospitalizations and increased demand for open services. The statistical tests demonstrated that opinions about concepts differ between the subjects. Differences between the domains (concept and care) were found for the 3 services. The lowest average scores in concept were found in PSC for patients (2.36) and their partners (2.20).

Conclusions: The tests demonstrated that opinions on the concepts differ between the subjects, with larger agreement between patients and caretakers at the Emergency unit. The differences in opinion reflect a time of changes in concepts, ideologies and psychiatric care.

MAJOR DEPRESSION AND MARITAL ADJUSTMENT

INSTITUTIONS
1. Institute of Mental Health, Serbia and Montenegro

AUTHORS
1. Goran Gajic
2. Saveta Draganic-Gajic
3. Ivana Perunicic
4. Dusica Lecic-Tosevski

Introduction: Numerous studies have found a relationship between marital distress and depression. Distressed couples where one of the partner is depressed have generally been found to interact more negatively, they report lower level of intimacy, less ability to resolve conflict and less marital satisfaction. However, it is still unclear if this is a consequence of both partners being depressed or if the poorer quality of relationship led to emotional distress of the carer.

Method: The clinical sample of 25 inpatients diagnosed with major depression and their partners were assessed. All participants were evaluated for depressive symptomatology using Hamilton Psychiatric Rating Scale for Depression (HAM-D) and for marital adjustment using Dyadic Assessment Scale (DAS).

Results and conclusion: The obtained results concerning marital maladjustment in distressed couples with a depressed partner are discussed in a context of significant impact of depressive disorder on partner’s relationship through the specific interaction and emotional burden which depression imposes on the carer.

VALIDITY OF PERCEIVED CRITICISM: AN INDEX OF ACTUAL INTERACTIVE BEHAVIOUR?

INSTITUTIONS
1. University of Groningen, Clinical and Developmental Psychology, Groningen, The Netherlands
2. University of Groningen, Interuniversity Center for Social Science Theory and Methodology, Groningen, The Netherlands

AUTHORS
1. Coby Gerlsma, Dr, PhD, J.Gerlsma@rug.nl
2. Marijtje A.J. van Duijn, Dr, PhD, M.A.J.van.Duijn@rug.nl

Aims
Expressed Emotion (EE) research has shown that a critical attitude in psychiatric patients’ spouse or relative adversely affects the course of various disorders, such as schizophrenia, depression, anxiety, PTSD, and eating disorders. Recent reviews (Hooley & Parker, 2006; Renshaw, 2007) recommend clinicians and researchers to use the selfreport instrument Perceived Criticism (PC) as a (very) short and practical measure of EE. In it’s most simple form, PC addresses the patient’s view with the single item “How critical is your spouse/relative of you?”; to remedie the unstability associated with single-item measurement, multi-item scales have been developed too. Like EE, PC predicts the course of various psychiatric disorders. However, little is known about PC’s validity. In this study, we examined to what extent PC is a reflection of how partners actually interact with each other.

Methods
N=34 couples from the general community completed selfreports of PC and participated in a videotaped problem solving interaction.

The verbal and nonverbal features of the interactions were coded with the Kategoriensystem für partnerschaftliche Interaktionen (KPI); interrater reliability was satisfactory.

Results
Multilevel analyses showed that PC-scores were consistently related to objective ratings of the partners’ verbal and nonverbal expressions of criticism. Individuals who perceived (and received) more criticism also tended to express more negative nonverbal behaviour.

Conclusions
Findings fit in well with theoretical formulations regarding EE, and support the usefulness of PC-measures as practical alternatives for the assessment of EE.

AUTHORS
1. Coby Gerlsma, Dr, PhD, j.gerlsma@rug.nl
2. Marijtje A.J. van Duijn, Dr, PhD, M.A.J.van.Duijn@rug.nl

Aims
Expressed Emotion (EE) research has shown that criticism in psychiatric patients' spouse or relative adversely affects the course of various disorders, such as schizophrenia, depression, anxiety, PTSD, and eating disorders. Recent reviews (Hooley & Parker, 2006; Renshaw, 2007) recommend clinicians and researchers to use the self-report Perceived Criticism (PC) as a (very) short and practical measure of EE. In its most simple form, PC addresses the patient's view with the single item “How critical is your spouse/relative of you?”; multi-item scales have been developed too. Like EE, PC predicts the course of various psychiatric disorders. However, little is known about PC’s validity. We examined whether PC is biased by the perceiver's current depressive and marital complaints, and whether PC measures reciprocal criticism, characterizing dyads rather than individuals.

Methods
N=40 couples from the general community completed self-reports of PC, depressed mood, and marital dissatisfaction, and expressed their feelings about their partner in a brief EE-interview (Five Minute Speech Samples).

Results
Multilevel analyses suggested that PC-scores depended primarily on the partner's expressions of criticism, and to a lesser extent on the perceiver's depressive and marital complaints. Partners strongly agreed in PC, and individuals who perceived more criticism also tended to express more criticism, suggesting that PC is an index of reciprocal criticism within dyads.

Conclusions
Findings fit in well with theoretical formulations regarding EE, and support the usefulness of PC-measures as practical alternatives for the assessment of EE.

2. Konstantinos N Fountoulakis
3. Zoltan Rihmer
4. Gyorgy Bagdy

Introduction: There has been expanding interest in research concerning the genetic background of personality traits and characteristics. One of the most frequent candidates in psychiatric genetics is the 5-HTTLPR polymorphism of the serotonin transporter gene, which has been found to be associated with neuroticism-related personality traits and psychiatric disorders. Although the role of the serotonergic system in the background of aggression is well-known, few studies have so far focused on the relationship between the 5-HTTLPR polymorphism and aggressive personality traits. The aim of our study was to investigate the association of the s allele of the 5-HTTLPR polymorphism with aggressive traits in a psychiatrically healthy population.

Methods: 169 healthy females participated in the study. All participants completed the Buss-Durkee Hostility Inventory (BDHI), and were genotyped for 5-HTTLPR using PCR. Scores of subjects carrying and not carrying the s allele were compared with ANOVA.

Results: We found that the presence of the s allele was significantly associated with higher scores on the Guilt, Hostility and Global Aggression scales of the BDHI.

Conclusions: Our study confirms a significant role of the serotonergic system and the 5-HTTLPR in the emergence of aggressive traits even in a psychiatrically healthy population, however, the polygenic and multifactorial determination of personality traits should also be considered. Furthermore, our study provides yet another significant correlate of the s allele of the 5-HTTLPR related to personality, traits and temperaments, and brings us closer to understanding the role of the 5-HTTLPR in the background of personality and psychiatric disorders.

2. Konstantinos N Fountoulakis, Dr, MD, PhD
3. Judit Lazary, Dr, MD
4. Zoltan Rihmer, Prof, MD, PhD, DSc
5. Gyorgy Bagdy, Dr, MD, PhD, DSc

Background: It has been earlier described that the 5-HTTLPR polymorphism is associated with anxiety-related traits and anxiety disorders. The relationship between 5-HTTLPR genotype and anxiety has also been confirmed in neuroimaging studies. However, subsequent experiments investigating different populations and different methodology to assess anxiety and anxiety-related personality traits yielded conflicting results. The aim of our study was to investigate the association of anxiety and 5-HTTLPR in a psychiatrically healthy population using multiple self-report questionnaires to measure anxiety and anxiety-related traits.

Method: 169 psychiatrically healthy women participated in the study. The participants completed the STAI, the SCL-51 anxiety subscale, the CPI anxiety subscale, the Harm Avoidance subscale of the TC1, and the Anxious temperament subscale of the TEMPS-A. All participants were genotyped for 5-HTTLPR using PCR.

Results: Subjects carrying the s allele had a significantly higher score on both the state and the trait anxiety subscale of the STAI, on the SCL-51 anxiety subscale and the TEMPS-A anxious temperament subscale. No significant difference between the two groups emerged in case of the CPI anxiety subscale and the Harm Avoidance scale of the TC1.

Discussion: Our results support the association between the 5-HTTLPR and anxiety and anxiety-related traits. Our results also suggest that previous contradictory results concerning the association of this polymorphism with anxiety are in part related to the instrument used to assess anxiety. Therefore it should be analysed what aspects of anxiety each of the questionnaires measure to gain a deeper understanding into the relationship between anxiety and the 5-HTTLPR.

Aims: Traumatic events experienced such childhood maltreatment increase the risk for psychiatric morbidity in the adulthood, particularly affective disorders and posttraumatic stress disorder (PTSD) (1). In addition, both depression and PTSD are related to psychoneuroimmunologic alterations (2). The aim of this study was to evaluate both neuroendocrine and immunological variables in depressed females reporting severe childhood neglect and current PTSD symptoms.

Methods: We screened recurrent depression female outpatients (20-40 years) for PTSD symptoms and severe childhood emotional neglect (CEN) and grouped as following: +PTSD/+CEN (n=17), +PTSD/-CEN (n=10), and -PTSD/-CEN (n=14). A healthy control group (n=20) also took part in the study. PBMCs were isolated and stimulated with mitogen (PHA) and various concentrations of dexamethasone (DEX), epinephrine or dehydroepiandrosterone sulphate (DHEAS). Proliferation/viability was assessed by MTT assay. Specific CD4+/CD8+ proliferation was investigated by CFSE staining and proliferation measured by flow cytometry. Morning salivary DHEAS levels were measured by radioimmunoassays.

Results: Patients had a similar DHEAS levels, cell proliferation and sensitivity to DEX, epinephrine and DHEAS. However, lymphocytes of PTSD patients had reduced sensitivity to DEX (p < .05).

Conclusions: Our results suggest that PTSD and emotional neglect are associated with immunological changes that resemble those found during healthy aging.

DIFFERENTIATION OF FACIAL EXPRESSIONS BY MEANS OF OSCILLATORY DYNAMICS

INSTITUTIONS
1. Istanbul Kultur University, Brain Dynamics Cognition and Complex Systems Research Unit, Istanbul, Turkey

AUTHORS
1. Bahar Guntekın¹, Dr., PhD, b.guntekin@iku.edu.tr
2. Erol Basar¹, Prof. Dr.

Aims/Objectives: Changes in mood disorders belong to relevant research topics in Psychiatry. According to the vast references observation of face expressions affect emotional states of healthy and pathologic subjects in different ways.

Methods: We applied the approach of Event Related Oscillations (EROs) for investigating the modulation of electrical manifestations related to emotional expression in EEG recordings of 20 healthy subjects. EROs of “Neutral, Angry, and Happy” faces in 13 electrical recordings sites (F3, F4, Cz, C3, C4, T3, T4, T5, T6, P3, P4, O1, O2) were analyzed. Following the recording session, the subjects were asked to express the degree of their emotional involvement (valence and arousal) using the Selt Assessment Manikin ratings. Amplitude frequency characteristics (aFCs) were used to determine the frequencies bands for digital pass-band filtering applied accordingly.

Results: A differentiation between angry and happy facial expressions, were observed especially in the alpha (9-13 Hz) and beta (15-24 Hz) frequencies, however, only when selecting stimuli with high mood involvement. The amplitudes of the alpha responses upon angry face stimulation were significantly higher than upon presentation of the happy faces at posterior locations. At F3, Cz and C3 recordings beta responses upon angry face stimulation were significantly higher in amplitude compared with the happy face stimulation.

Conclusion: Since the observation of facial expressions of healthy subjects show relevant differences in alpha and beta responses of the analysis of oscillatory dynamics will possibly open a new avenue in the electrophysiological analysis of psychiatric patients upon presentation of pictures with different face expressions.

Aim: To assess if psychosocial assistance of Humanitarian Association of “Friends” decrease prevalence of posttraumatic stress disorder (PTSD) and depression in primary and secondary schools students in Postwar Bosnia and Herzegovina.

Methods: The sample of 408 primary and secondary schools’ students from Bosnia and Herzegovina aged 13.6±1.9 years, consisted from two groups. The group of 336 students that involved in psychosocial assistance was compared with the group of 72 randomly selected students of same-age from the same schools that were not involved in this assistance. Data were collected two times: in beginning of December 2005 and again at the end of May 2006. According to DSM IV we used the Index of Children Post-traumatic reactions for measuring symptoms of posttraumatic stress disorder (PTSD) and the Children Depression Inventory (CDI) for symptoms of depression.

Results: The prevalence of PTSD, among students involved in psychosocial assistance of Humanitarian Association of “Friends”, decreased from 46.1% to 13.4%, (P<0.001, McNemar’s test), whereas in the control group this reduction was not significant, from 30.5% to 23.6%, (P=0.332, McNemar’s test). Also, prevalence of depression among the students involved in the psychosocial assistance was significantly reduced, from 25.6% to 1.8% (P<0.001, McNemar’s test), whereas in the control group this reduction was not significant, from 22.2% to 11.1%, (P=0.077, McNemar’s test).

Conclusion: This study suggests that psychosocial assistance to students within the Humanitarian Association of “Friends” resulted with significant reduction of PTSD and depression.

4. Sanja Kurtovic
5. Hajrudin Haracic

Aim: To assess the psychological health of war-traumatized adolescents in rural and urban areas of Bosnia and to determine it’s correlation hopelessness.

Method: The study was carried out in Teoak and Tuzla, Bosnia and Herzegovina, in March 2007. We assessed 366 elementary and secondary school adolescents (175 girls), aged 15.3±1.4 years, for war trauma, presence of posttraumatic stress disorder (PTSD), depression, and hopelessness. There were 193 adolescents (105 girls) from the rural area and 173 (70 girls) from the urban area. For data collection, we used The War Trauma Questionnaire, The Hopelessness Scale for Children (HSC) and The Children’s Depression Inventory (CDI).

Results: PTSD was present in 40.4% of 366 adolescents, with a significantly higher prevalence amongst rural adolescents (53.9%) than urban (25.4%) (Chi-square=30.662, P<0.001). Depression was present in (28.6%) of 366 adolescents, with no statistical difference between the rural and urban groups (P=0.096). All adolescents reported high hopelessness scores with no difference between groups. Prevalence of PTSD was positively correlated with the prevalence of depression (Spearman’s r=0.293; P<0.001). Academic achievements were negatively associated with age, severity of PTSD, depression, suicidal thoughts, hopelessness and with the mean number of trauma experiences.

Conclusions: The war-related experiences of the adolescents were of different types and were associated with a variety of psychological sequel. A significantly higher prevalence of PTSD, often co-morbid with depression, was found among adolescents from the rural area.

Key words: war, postwar, Bosnia-Herzegovina, posttraumatic stress disorder, adolescents, hopelessness

Aim: To estimate presence of Posttraumatic Stress Disorder (PTSD), Depression, Anxious disorder, Cigarettes and Alcohol misuse amongst war veterans of Army of Republic Bosnia and Herzegovina (ARBH), employed in Military Forces (MF) of Bosnia and Herzegovina 11.5 years after war 1992-1995 in Bosnia and Herzegovina (BiH).

Methods: We tested a sample of 114 male war veterans aged 37.3±4.9 year in March 2007. For assessing of frequency of trauma experiences and PTSD prevalence we used the Harvard Trauma Questionnaire (HTQ). For assessing presence of depression and anxiety we used Hopkins scales for depression and anxiety (HPQCL) version for Bosnia and Herzegovina. Prevalence of nicotine and alcohol misuse we assessed by use of Fagerstrom questionnaire and Michigan Alcoholism Screening Test (MAST).

Results: Among 114 tested war veterans mean number of reported war trauma experiences were 19.8±6.2. We found that 48 (42.1%) were wounded. Amongst 22 (19.3%) of 114 veterans PTSD symptoms registered that meet DSM-IV criteria. At 32 (33.0%) of 97 and at 52 (53.1%) of 98 veterans registered symptoms that meet DSM-IV criteria for clinical depression and anxiety, respectively. Amongst tested war veterans 52 (45.6%) smoke cigarettes and 56 (49.1%) of 114 drink alcohol.

Conclusions: War veterans of ARBH presented high level of PTSD, depression and anxiety more than eleven years after war quitted. Cigarette smoking and alcohol drinking registered at almost one half of war veterans employed in Military Forces of Bosnia and Herzegovina.

Key words: Bosnia and Herzegovina, War veterans, Military Forces, PTSD, Depression, Anxiety, Cigarette smoking, Alcohol drinking

BRAIN ACTIVITY FOR NOVELTY DETECTION AND CATEGORY SPECIFICATION PROCESSES IN DEMENTIA PATIENTS AND AGED-MATCHED CONTROLS: AN FMRI STUDY.

INSTITUTIONS
1. University of Birmingham, Department of Psychiatry, Birmingham, United Kingdom
2. Birmingham & Solihull Mental Health Trust, Birmingham, United Kingdom
3. University of Birmingham, Department of Psychology, Birmingham, United Kingdom

AUTHORS
1. Paul Pope¹, Dr., p.pope@bham.ac.uk
2. Reinhard Heun¹, Prof., r.heun@bham.ac.uk
3. Jose Schwartz², Dr.
4. Zoe Kourtzi³, Prof.

Objectives: We used functional magnetic resonance imaging (fMRI) to investigate cognitive processes such as novelty detection (ND) and category specification (CS) in patients with mild cognitive impairment (MCI) and Alzheimer’s disease (AD), and healthy aged controls. Both ND and CS involve the hippocampus: the first brain structure affected in AD. Unique patterns of brain activity associated with these memory processes may dissociate MCI patients into those that develop AD, and those that do not.

Methods: Patients (MCI and AD) and controls performed a passive picture-viewing paradigm while inside a 3T scanner. In each session, blocks of pictures belonging to four different semantic categories (FACES, BODY PARTS, TOOLS & SCENES), scrambled versions of picture blocks and repeated picture blocks were presented. Relative to fixation baseline, the contrast between picture and scrambled picture blocks, and new and repeated picture blocks revealed cortical and sub-cortical areas associated with CS and ND processes, respectively. In total, eight sessions were run per subject.

Results: Preliminary data reveal category-specific and novelty-specific regions, both of which involve medial temporal lobe structures, including the hippocampus. Unique processing “modules” in frontal and temporal regions of cortex also accompany the visual processing of different semantic categories.

Conclusion: Distinct patterns of brain activity associated with ND and CS processes may enable the early detection of AD in MCI patients, especially those at higher risk for developing future AD. This could become an important tool for the clinical diagnosis of AD dementia.

AN INTERVENTION PROGRAM FOR EMOTIONAL/BEHAVIORAL PROBLEMS AMONG FEMALE ADOLESCENTS UNDER PROBATION USING SATIR MODEL

INSTITUTIONS
1. Nanya Institute of Technology, General Education Center, Jhongli City, Taoyuan County, Taiwan Republic of China

AUTHORS
1. Chi-Yin Ho¹, Dr., PhD, waterho93@yahoo.com.tw

Aims: To evaluate the efficacy of an intervention program using Satir model on emotional/behavioral problems among female adolescent probationers.

Methods: Female probationers (N=5) aged 15 to 18 from five probation officers in one local court of Taiwan were consecutively selected as intervention group. All probationers and their family members participated in a 6-session intervention program based on the family system theory developed by Virginia Satir. The intervention was held once a week by the probation officers through face-to-face interview with all family members. A control group (N=10) of female probationers receiving general in-person interviewing per week from the same probation officers was selected. The efficacy of the program was evaluated by comparing emotional/behavioral problems before and after the intervention using the parent’s, teacher’s, and self-report of the Child Behavior Checklist.

Results: After the intervention, subjects reported themselves to have a significant lower score on Delinquent Behavior (t=3.18, p<0.05), Aggressive Behavior (t=3.40, p<0.05), and Externalizing (t=3.14, p<0.05) than before the intervention. Similarly, teachers reported significantly lower scores on Delinquent Behavior (t=3.37, p<0.05), Aggressive Behavior (t=3.22, p<0.05), Externalizing (t=3.30, p<0.05), and Total Problems (t=3.65, p<0.05). However, parents reported a significant lower score on Social Problems (t=5.22, p<0.05) and Total Problems (t=5.50, p<0.05). Controls showed changes on none or fewer behavioral problems.

Conclusion: Interventions based on the family system theory of Satir model are effective in reducing the manifestation of emotional/behavioral problems among female adolescent probationers. Practitioners in judicial systems may consider dealing with emotional/behavioral problems of adolescent probationers by such strategy.

PSYCHOMETRIC PROPERTIES OF THE TEMPERAMENT AND CHARACTER INVENTORY REVISED (TCI-R) IN CZECH ADOLESCENT SAMPLE

INSTITUTIONS
1. Medical Faculty of Masaryk University, Research Institute of Preventive and Social Paediatrics, Brno, Czech Republic

AUTHORS
1. Veronika Hublova¹, Ms, M.a., veronika.hublova@gmail.com
2. Mojmir Snopek¹, Mr., M.a., mojmir.snopek@gmail.com

We explore the psychometric characteristics of the Cloninger’s personality questionnaire (TCI-R) in the cohort of fifteen year olds. As the age of fifteen is the lowest recommended age to use the adult version of the method, we aim to present the data in the context of gender differences, the normative of Czech general population data and adolescent population of other countries. The cohort of 787 subjects was collected from Czech branch of the ELSFAC longitudinal study; the data were stratified according to gender and series of t-tests and factor analyses were performed. We have confirmed the normal distribution and homogeneity of the sample, the internal consistency of most scales approached the satisfactory limit of 0.70. The principal component analyses confirmed the factorial structure except the facets of NS1, RD4 and SD4 which load more other dimensions. Girls had generally higher scores in Harm Avoidance, Reward Dependence and Cooperativeness than boys. Their scores deferred significantly from boys’ in almost all facets and dimensions of TCI-R, which is neither found in Czech general population but is slightly more in consent with the results of previous testing of the adolescents by the TCI-R. The Czech version of the questionnaire might be useful tool for the study of personality dimensions of fifteen year olds with the respect to their age that requires different normative data than of the adults. Perhaps this also indirectly points out the issues of general personality development.

3. Jung-Young Lee³, Dr., MD, PhD

Objective: The aims of this study were to investigate the frequency and the profile of depressive symptoms in the Korean adults with major depressive disorder.

Methods: Face-to-face interviews were conducted with the Korean version of Composite International Diagnostic Interview 2.1/DSM-IV. A total of 6,275 participants completed the CIDI interview, which included 26 depressive symptom items presented by DSM-IV and ICD-10.

Results: Frequent depressive symptoms were identified. The items included fatigue (90.3%), concentration difficulty (86.9%), depressed mood (84.0%), insomnia (83.7%), loss of interest (77.0%), decreased appetite (77.3%). There were gender differences. Loss of interest, fatigue, hypersomnia, psychomotor retardation, feeling guilty, suicide attempt, and loss of pleasure were identified more frequently in female, while indecisiveness and decreased libido were identified more frequently in male. Concerning age, depressed mood, insomnia, psychomotor agitation, and feeling guilty were more prevalent in old adults, while loss of interest, fatigue, and hypersomnia were more prevalent in young adults.

Conclusions: Symptomatology of depression is different according to depressive symptom items, gender, and age

2. Eugene Seo
3. Un Sun Chung
4. Hyo Deog Rim
5. Sunghoon Jeong
6. Byung-Jo Kang
7. Seung Jae Lee

Objective: This study aimed to understand the characteristics of salivary α-amylase reactivity, as a biological marker of stress, by viewing negative affective pictures.

Method: 36 healthy volunteers completed baseline psychological assessment prior to experiment. The 20 negative affective pictures from the IAPS were presented to evoke negative emotion for 5 minutes. Saliva samples were collected before and 0-, 5- and 10-min after the completion of exposure and assayed for α-amylase. To detect psychological change, Positive Affect and Negative Affect Schedule, State-Trait Anxiety Inventory-State were measured just before and 10-min after stimuli.

Result: Overall, salivary α-amylase was significantly decreased over time with the increase of negative affect (NA) score and state-anxiety. The NA scores were correlated not only with the baseline level but with change of α-amylase between before and 0-min after the completion of the exposure. Further comparison between subjects with higher (≥ 2 in NA score change) and those with lower (< 2) susceptibility to negative affect revealed that the baseline level of α-amylase was lower in high susceptible group than in low susceptible group with predictive value approaching significance. After the exposure, the mean change of α-amylase between baseline and 10-min was significantly different between high and low susceptible group.

Conclusion: While subjects with high susceptibility to negative affect showed low baseline α-amylase level with low α-amylase reactivity, those with low susceptibility revealed high baseline α-amylase with high reactivity. These findings suggest that the baseline level of salivary α-amylase and its reactivity depend on individual reactivity to affective stress.

MENTAL HEALTH CONDITIONS AMONG FAMILIES OF CHILDREN WITH CONGENITAL MUCOPOLYSACCHARIDOSIS IN JAPAN

INSTITUTIONS
1. Omura Kyoritsu Hospital, Neuropsychiatry, Omura, Japan
2. Research Center for Tropical Infectious Diseases, Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan

AUTHORS
1. Yoshihiro Imamura, Dr., Md, y-imamura@camellia.or.jp
2. Syunichi Funakoshi, Dr., Md, funakoshi@camellia.or.jp
3. Sumihisa Honda, Mr., Md, honda@net.nagasaki-u.ac.jp
4. Naoko Kamada, Mrs., kamada@camellia.or.jp

Objectives: The aim of this study was to evaluate the mental health conditions among families of patients with congenital mucopolysaccharidosis (MPS).

Methods: Subjects were the families of patients with MPS. The General Health Questionnaire 12-item version (GHQ-12) was used to assess the subjects’ mental health conditions, while the Impact of Events Scale-Revised (IES-R) was used to assess the experiences of emotional trauma, such as the notification of diagnosis and the subsequent difficulties associated with daily care. In addition, a qualitative analysis by using in-depth interview was conducted on the subjects. Utmost care for ethical consideration was taken to protect the privacy of subjects.

Results: Responses were obtained from 11 family members of patients with MPS by December 2007. A high GHQ-12 score, as defined when the score exceeded the threshold value of 3, was observed in 4 (36.4%) subjects. A high IES-R score, as defined when the score exceeded the threshold value of 24, was also observed in 5 (45.5%) subjects. Qualitative analysis revealed that subjects had a sense of loss regarding the future, in addition to deterioration of relationships with others. They expressed strong expectations for support from others, especially self-help groups.

Conclusion: The present findings suggested that families of patients with MPS are strongly affected of their mental health by psychological impact and burden. Emotional support appropriate for the specific nature of illness should be developed.

LIFETRACK THERAPY - TREATING PERSONALITY GUIDED BY DAILY SELF-RATING BY THE PATIENT ON 41 PARAMETERS

INSTITUTIONS
1. Independent Private Practice, New York, United States

AUTHORS
1. Yukio Ishizuka¹, Dr., MD, dri@lifetrack.com

Objective: To demonstrate that ‘Breakthrough Intimacy’ - closeness between committed couples far greater than their previous maximum experience can predictably transform couples’ personalities, eliminating psychiatric symptoms (such as anxiety, anger, physical-symptoms, depression, and symptoms of borderline personality disorder) without medications and often within 6 months.

Method: The therapist actively guides couples to think, feel, and act in such ways that their closeness will increase through conscious and unnatural efforts, provoking and overcoming waves of symptom spikes (defense) until they disappear by exhaustion, guided by the couples’ own daily self-ratings on 41 parameters that allow accurate graphic tracking via Internet of subtle changes in personalities and dynamic mental status.

Results: Of the 1,170 patients treated for various symptoms over the last 20 years, 48% reached a level of adjustment higher than their previous maximum level, beyond symptom elimination. Among them, 31% reached a level more than twice, 24% reached more than three times, 20% reached more than four times, 16% reached more than five times, and 7.6% reached more than ten times their previous maximum level according to their own daily subjective self-rating. Of those who failed to reach their previous maximum level before premature terminations, 75% showed significant improvement in overall adjustment and 77% showed significant reduction of symptoms.

Conclusion: Psychiatric symptoms may be better understood and treated as consequence of one’s personality, which can be transformed through ‘Breakthrough Intimacy.’ The results of this study prove that patients’ own daily self-rating provide powerful evidence as well as means of change.

BRIEF COACHING ON AUTOGENIC TRAINING (AT)

INSTITUTIONS
1. Azerbaijan Medical University, Psychiatry, Baku, Azerbaijan

AUTHORS
1. Nadir Ismayilov¹, Professor

AT is one of the most effective therapeutic techniques focused on self-suggestion. The proposed method promotes quick and effective acquisition of AT skills. According to the guideline an experienced therapist trains a group of 20-40 patients sharing the similar intellectual capabilities and the same level of awareness of AT. The training is provided once a week and in the intervals the trainees practice AT for a quarter of an hour three times a day. The approach reduces time of training up to one month. Teaching skills of a therapist and group discussion of training process promote positive results in the patients.

BURNOUT SYNDROME IN POSTGRADUATE TRAINING IN MEDICINE AT A GENERAL HOSPITAL LIMA PERU

INSTITUTIONS
1. Hermilio Valdivian Hospital, Lima, Lima, Peru

AUTHORS
1. Luz Milagros Jara Pereda, Doctor, MD, milagrosjarapereda@hotmail.com

The Syndrome of Burnout is defined as a analadaptive response to chronic labor stress experienced by professionals who work in direct contact with people, among them the health personnel. Medical residents are a vulnerable population to suffer this dysfunction, due to the combined clinical work and academic demands characteristic of clinical training years.

The present study of descriptive and cross-sectional type evaluated the prevalence of the Burnout Syndrome in medical residents at the Arzobispo Loayza Hospital in Lima, Peru. For this purpose, the Maslach Burnout Inventory was applied (MBI) and socio-demographic data was recorder. It was found that the prevalence of Burnout Syndrome at moderate risk was exhibited by 55.9% of the sample, and considering the entirety burnout risk range it affected 78.7% of the sample. There was statistically significant relationship between Burnout Syndrome and number of working hours as well as number of on-call days and nights.

Key words: Burnout Syndrome, medical training.

7. Karim Tabbane, Dr., k_tabbane@yahoo.fr

The aim of this study was to construct a battery of cognitive tests which is adapted to Tunisian cultural and linguistic context and to offer normative data in Tunisian Arabic dialect speaking healthy subjects.

A first step in developing such a battery was to choose easy speed of processing tasks, consisting of seven tests exploring attention, memory, verbal fluency and executive motor function. These tests derived from standardized batteries (BACS, MATRICS and WAIS) and were adapted to our linguistic and cultural context. Then, we proceeded to their administration in a sample of healthy Tunisian subjects.

We obtained normative data of cognitive performances across age, education and gender. Age and gender did not impact test performance. Long education had a significant positive association with a good performance on cognitive measures of the battery.

To conclude, this cognitive assessment battery is appropriate for use in Tunisian speaking populations. Its use may be extended to patients suffering of schizophrenia by comparing their performances to those of controls matched for education.

EFFECT OF MONTH OF BIRTH ON PERSONALITY TRAITS OF HEALTHY JAPANESE

INSTITUTIONS
1. Yamagata University, Health Administration Center, Yamagata, Japan
2. Yamagata University School of Medicine, Department of Psychiatry, Yamagata, Japan

AUTHORS
1. Mitsuhiro Kamata1, Dr, MD, PhD, mkamata@med.id.yamagata-u.ac.jp
2. Akihito Suzuki2, Dr, MD, PhD
3. Yoshihiko Matsumoto2, Dr, MD
4. Hitoshi Togashi1, Dr, MD, PhD
5. Koichi Otani2, Dr, MD, PhD

Effect of season of birth on personality traits was investigated in 595 healthy Japanese. Personality traits were evaluated by the Temperament and Character Inventory, which has seven dimensions. Months of the year were divided according to temperature or photoperiod. Males born during the three months with the highest temperature, i.e., July to September, had significantly lower scores of self-directedness than those born during other months, while females born during the same period had significantly higher scores of self-directedness and persistence than those born during other months. Both males and females born during the three months with the longest photoperiod, i.e., May to July, had significantly higher scores of cooperativeness than those born during other months. The results of the present study suggest that month of birth affects some personality traits, especially self-directedness and cooperativeness, in healthy Japanese, and these effects may be mediated by temperature and photoperiod during the gestational or perinatal period.

5. Alexandros Papadimitriou4
6. Nikiforos V Angelopoulos1

Objectives: It is shown that major depression may be accompanied by disorders in positive and negative acute phase proteins. Major depression is associated with higher plasma levels of positive acute phase proteins such as haptoglobin, ceruloplasmin, hemopexine and a1-antitrypsin, and lower plasma levels of negative acute phase proteins such as transferrin, albumin and retinal binding protein. These results may indicate that some major depressed subjects suffer from an inflammatory (the acute phase) response.

Materials and methods: We examined perimenopausal women with depression and a comparison group of non-depressed perimenopausal women. The diagnosis of depression was determined by an interview and the Hamilton Depression Rating Scale (HAM-D). A total of 64 women were assessed. Haptoglobin, transferrin, a1-antitrypsin and C-reactive protein were analyzed with standard laboratory methods. Pearson’s correlations were applied to evaluate the relationship between acute phase proteins and depressive mood.

Results: Women with perimenopausal depression did not differ from the non-depressed comparison group in plasma levels of the acute phase proteins.

Conclusions: The lack of association of acute phase proteins and depressive mood reported in this study does not support previous findings in patients with major depression. This negative finding in milder forms of depression in perimenopausal women indicates either the absence or a more complex nature of the interactions between acute phase proteins, low grade inflammation and depression.

THE ASSOCIATION OF VASOMOTOR SYMPTOMS WITH PERIMENOPAUSAL DEPRESSION

INSTITUTIONS
1. University of Thessaly, Department of Psychiatry, Larissa, Greece
2. Psychiatric Hospital of Attiki, Department of Medicine, Athens, Greece
3. University of Thessaly, Department of Obstetrics and Gynecology, Larissa, Greece
4. University Hospital of Larissa, Biochemical Laboratory, Larissa, Greece

AUTHORS

Objectives: Menopausal symptoms of hot flushes and night sweats are defined as vasomotor symptoms. They are markers of declining serum estradiol, are not universal in menopausal women and may occur in women who are sensitive to the effects of estradiol on thermoregulatory centers and serotonergic, adrenergic, and norepinephrine neurotransmitters.

Materials and Methods: We examined perimenopausal women with depression and a comparison group of asymptomatic perimenopausal women. All women were between the ages 40 and 55 and presented with a history of menstrual cycle irregularity of at least six months duration but not longer than one year of amenorrhea. The diagnosis of depression was determined by an interview and the Hamilton Depression Rating Scale (HAM-D). Vasomotor symptoms were assessed with the Menopause Rating Scale (MRS). Plasma thyroid hormone levels were also measured.

Results: A significant relationship between vasomotor symptoms and depression was found in perimenopausal women. Moreover, the plasma levels of T3 and TSH were higher (p<0.03) in climacteric women who had vasomotor symptoms.

Conclusions: Hot flushes and night sweats are associated with depression in perimenopausal women. It appears that thyroid function plays a key role in the appearance of vasomotor symptoms and consequently of depression in perimenopausal women.

Introduction and objectives: Schizophrenia is a condition with highly variable course that is hard to predict. The aim of the study was to evaluate the utility of regional features of brain morphology at the time of the first episode of schizophrenia for the prediction of one-year treatment outcome.

Method: 32 first-episode schizophrenia patients were assessed at the time of the first episode of schizophrenia and one year later. Baseline regional gray matter volume was correlated with the Global Assessment of Functioning scale score obtained one year after the first episode. Regional gray matter volume parameters of the patients were compared with healthy controls matched for age and sex.

Results: Schizophrenia patients had lower gray matter volume in both the left and right prefrontal cortex. Left prefrontal cortical gray matter also correlated positively with the GAF score, i.e. the more prefrontal gray matter the better functional status one year after the first episode.

Conclusion: Prefrontal gray matter volume is linked with the long-term functional outcome after the first episode of schizophrenia and it is possible to use it for the outcome prediction.

Objectives: Delirium after head trauma results in various cognitive and behavioral dysfunction. This study aimed at developing and validating a predictive model for clinical improvement after delirium based on precipitating factors during hospitalization.

Method: Data were collected on 45 patients who developed delirium after head trauma using 5 year retrospective design, based on reviews of medical charts including psychiatric consultation reports. The differences of the group who sustained residual symptoms of delirium (RS group) and the group of full recovery (FR group) at 4 week follow-up visits were compared by motoric type of delirium, socio-demographic variables, neuroimaging variables and clinical variables of interest.

Result: There was significant difference in reason for initial consultation between two groups, in terms of hyperactivity (p<.01). The presence of compensation claim and subcortical gray matter lesion was significantly associated with the RS group (p<.05). Total length of intensive care unit (ICU) admission and of hospital stay were significantly longer in RS group than FR group (p<.01).

Conclusion: This study shows that hyperactivity on initial consultation, compensation claims, specific brain lesion were altogether significant factors in explaining prolonged duration of delirium after head trauma. A simple predictive model based on the presence of precipitating factors might be used to identify delirious patients at high risk for prolonged cognitive dysfunction. Early psychiatric intervention would be required for evaluating efficacious management and shortening admission period.

THE EFFECT OF ANTIPSYCHOTIC DRUG TREATMENT ON SERUM VEGF, sVEGFR-1, AND sVEGFR-2 LEVEL IN SCHIZOPHRENIA

INSTITUTIONS
1. Chuncheon Sacred Heart Hospital, Hallym University, Psychiatry, Chuncheon, Republic of Korea

AUTHORS
1. Do Hoon Kim\(^1\), Dr., MD, PhD, dohkim@hallym.ac.kr
2. Yoo Sun Moon\(^2\), Dr., MD, PhD, yoosmoo@hallym.ac.kr

Object: The purpose of this study was to investigate the changes of serum levels of free VEGF, soluble VEGFR-1, and soluble VEGFR-2 after treatment with atypical antipsychotic drugs in schizophrenia.

Method: The schizophrenic patients were diagnosed with DSM-IV. 13 schizophrenic patients were evaluated their clinical assessment with serum level of free VEGF, sVEGFR-1, sVEGFR-2, and positive and negative symptom scale (PANSS) at baseline, 4 weeks, and 8 weeks after treatment with atypical antipsychotic drugs. 13 normal control subjects were recruited and matched with patient group by age and sex.

Result: In schizophrenia, PANSS score was significantly improved at 4 weeks and 8 weeks compared with baseline (p<0.05). The serum level of free VEGF and sVEGFR-2 at baseline in schizophrenic patients were not significantly different compared with control group, respectively. However, the serum level of sVEGFR-1 (86.2±10.3, p<0.05) was significantly increased in schizophrenia patients compared with control group (59.0±16.4). The serum level of sVEGFR-1 were significantly decreased at 8 weeks (57.3±6.3, p<0.05) after antipsychotic drug treatment. The serum level of sVEGFR-2 were decreased at 4 weeks (7761±403.0, p<0.05) and 8 weeks (7435±333.5, p<0.05) compared with baseline.

Conclusion: The serum level of sVEGFR1 was increased before treatment, and those of sVEGFR1 and sVEGFR2 were significantly decreased after antipsychotic drug treatment in schizophrenic patients. The decreased serum level of sVEGFR-1 and sVEGFR-2 might be affected by dopaminergic system which was influenced by antipsychotic drugs.

Aims: The purpose of this study was to investigate the relationships of childhood adversities and adult life events to depressiveness and cardiovascular disease.

Methods: The "Health and Social Support" is a prospective survey of the Finnish working-aged population. Altogether 83 % of the participants of the 1998 survey responded to the second survey five years later (n=19,629). The BDI was used to measure depressiveness and physical illnesses were inquired by asking about physician diagnosed illnesses. Other variables include history of depression, adversities in childhood family, and a checklist of 19 life events.

Results: Among women with childhood adversities the risk of depressiveness was significantly increased after a recent life event (1.81-fold). After adjusting for socio-demographic factors, smoking, alcohol consumption, social support, negative affectivity, baseline cardiovascular morbidity and person dependent life events the risk was still significant (1.48-fold). Among men the respective associations were a bit stronger as risk of depressiveness was 2.11-fold and after adjustments 1.84-fold. Recent life events did not increase risk of cardiovascular disease after recent life events among women and men after adjustments were made. Interestingly, in an analysis by type of recent events violence greatly increased risk of depressiveness and cardiovascular disease among men even after adjustments were made (OR=26.2, 95%CI: 6.99-96.1 and 23.6, 4.61-120.6, respectively) if one had experienced reported adversities.

Conclusions: Stressful experiences in early life and adulthood seem to increase risk of physical illness and depression.

PSYCHIC CONDITION OF THE HUNGARIAN SOLDIERS AFTER DEPLOYMENT

INSTITUTIONS
1. State Health Centre, Psychiatry, Budapest, Hungary

AUTHORS
1. Gábor Kovács¹, Dr, MD, kovacs-gabor@t-online.hu
2. Mónika Fekete¹
3. László Kovács³, Dr, MD

Objectives
Several data reveal that „healthy” soldiers show symptoms of various kinds of diseases after their foreign missions. The aim of our study was to evaluate the psychic condition of Hungarian soldiers after returning from their six or nine months peacekeeping deployment in Iraq and Kosovo.

Method
The participation in the study was voluntary and anonymous. The psychic condition was evaluated using „Life event scale”, „Davidson PTSD scale”, „STAI” and „SCL-90”. 280 soldiers deployed from Iraq were included in the study. Authors compared the results with data of 286 soldiers deployed from Kosovo and the Hungarian population.

Results
The most frequent psychotrauma in Iraq were the experience of explosion (29%) and some kind of battle action (30%). About half of the soldiers were traumatized and 6.3% showed PTSD syndromes. The level of trait and state anxiety was significantly higher in the PTSD group. The SCL-90 factors showed also significant difference between the PTSD and non-PTSD personnel. The postdeployment condition of the soldiers from Kosovo and Iraq differed only in the depression item, but each of their SCL-90 factors was significantly higher and the anxiety level was significantly lower than the Hungarian population’s.

Conclusion
Our study verified the effects of the acute (traumatic) and chronic stress of the deployment on the psychic condition of soldiers after their return from the mission. Results point out the importance of predeployment psychological trainings and postdeployment follow-up of the mental state of soldiers.

We performed immunobiological and immunochemical studies of some neuropsychiatric events. We focused our attention to analyze human peripheral blood natural killer cells, effector cells of innate immunity, equipped by neurotransmitter receptors and other important functional (lectin) receptors and their participation in antidepressant effects and treatment of major depressive disorder. It is supposed that blunted NK cytotoxicity can be related to major depression. We also studied NK cell aspects of autoimmune disorders, multiple sclerosis, with high incidence of depression disorder. We used functional tests of NK cytotoxicity using isotope ⁵¹Cr method, multicolor flow cytometry of Cd markers of NK cells and other immunocytes, mainly T cells and their subpopulations. We analyzed by immunochromical methods membrane trimeric G proteins coupled to neurotransmitter receptors as important postreceptor effects of different antidepressants on NK cells in vitro. Furthermore, changes of G alpha subunit profiles of main G proteins of granulocytes (effectors of innate immunity) during antidepressant treatment of patients with unipolar depression were estimated.

Our experiments indicate role of transduction mechanisms including G proteins and other phenotypical CD markers especially on peripheral blood NK cells or granulocytes as potential indicators of psychopharmacological/pharmacological treatment.

2. G. Rossa²
3. M. Wender³

Aims/ Objectives
So far, no definite genetic risk factor for sporadic cases of frontotemporal dementia FTD has yet been identified. There is still conflicting data from gene association studies. Several groups have examined the potential association of FTD with apolipoprotein E (APOE) genotype but the results are inconsistent. Therefore, an impact of APOE*² and APOE*⁴ alleles on FTD pathology remains still unclear. The aim of the study was to determine whether APOE gene polymorphism is a risk factor for Polish FTD patients.

Methods
The sample of 27 patients from Poznan region, ranging in age from 51 to 73 years, was diagnosed according to Lund and Manchester groups criteria. A cohort of 35 non-demented individuals in age from 50 to 70 years was used as a control group. APOE genotyping was carried out by PCR-RFLP analysis with the use of Hha I restriction endonuclease.

Results
The distribution of APOE genotypes and allele frequencies in patients was very similar to this observed among control subjects. No statistically significant difference was found.

Conclusion
There was no link between APOE genotype and FTD pathology in the analyzed sample of Polish patients. Moreover, we did not observe if any APOE allele has an effect on age at onset or duration of the disease.

Many studies have demonstrated lateralization of human brains at structural or functional levels and alterations in its degree in neurodegenerative (e.g. Alzheimer disease) or neurodevelopmental (e.g. schizophrenia) disorders (1). It is suggested that the brain asymmetry underlies specialization of particular hemispheres and that structural or functional lateralization can be supported also by a biochemical substrate. Although a direct relationship has not been established yet, right-left differences have been observed e.g. in some neurotransmitter systems (1). Our older experiments indicated a similarity between the human and Wistar rat brain asymmetry at a biochemical level and its possible use in animal models of brain disorders associated with alterations in brain laterality (2). The aims of the study were as follows: i) to evaluate the asymmetry of hippocampal cholinergic neurotransmitter system and of cortical nitric oxide neuromediator system in young male Long Evans rats, ii) to compare this asymmetry with human and Wistar rat brain laterality, iii) to determine changes due to normal aging, and finally iv) to establish if measurements of a biochemical substrate can be generally used in animal models of brain disorders. Our results suggest marked differences in biochemical asymmetry between Wistar and Long Evans rat brains, similar changes due to normal aging and advantages of similarly lateralized animals in modelling of human brain disorders.

Supported by MSMT (1M0517) project.

Abnormal serum and plasma activities of the cytosolic peptidases prolyl endopeptidase (PEP; EC 3.4.21.26) and dipeptidyl peptidase IV (DPP IV, EC 3.4.14.5) have been consistently observed in patients with mood disorders. However, the role of proline specific endopeptidases in basic mechanisms of depression remains unclear. Inhibitors of PEP have been shown to have antidepressant-like activity in mice in forced swimming test and modulate dopaminergic function.

Recently we have found that the development of dopamine deficit-dependent MPTP-induced depressive syndrome in rats is accompanied by activation of PEP and DPP IV in the brain frontal cortex and in the striatum. In the present study, the effects of novel synthetic PEP inhibitors benzylloxycarbonyl-methionyl-2(S)-cyano-pyrrolidine and benzylloxycarbonyl-allyl proline on behavioral deficits in rats with MPTP-induced depressive syndrome were examined. MPTP administration (20 mg/kg, i.p. daily for 14 days) resulted in lowering of preference for 10%-sucrose over water (anhedonia), decrease of daily liquid consumption, increase of immobility time (“behavioral despair”) and increase of rhythmological index of depression in forced swimming test. Competitive PEP inhibitor benzylloxycarbonyl-allyl proline (3mg/kg, i.p. daily, on 8-14th days of MPTP administration, 30 min before MPTP injection) promoted faster reduction of depression-like behavior in rats after MPTP withdrawal. Non-competitive PEP inhibitor benzylloxycarbonyl-methionyl-2(S)-cyano-pyrrolidine (1 mg/kg, i.p. daily, for 14 days on MPTP administration, 30 min before MPTP injection) prevented the development of “behavioral despair” and rhythmological disturbances in forced swimming test. The results obtained in the rat model of MPTP-induced depression syndrome demonstrate benzylloxycarbonyl-methionyl-2(S)-cyano-pyrrolidine and benzylloxycarbonyl-allyl proline to have antidepressant-like properties.

Aim: Neurofeedback therapy is a method allowing for a change of the bioelectrical functioning of the brain. By using the mechanism of instrumental conditioning, it changes the amplitude of selected brain waves. It allows for suppressing the waves of a too high amplitude and amplify the waves of a too low amplitude, with correlates with psychological and neurological disorders. In the described cases, primarily a global training was applied, than it was changed for a specific one.

Patients: The first case is a male aged 21 with an organic disorder of the CNS. In the childhood he was suspected of microcephaly. In that period a little retardation of his psychomotor development was observed. In the neurological examination signs of a vegetative dysregulation were found without focal dysfunctions of the CNS.

Results: The therapy significantly improved the functioning of attention, and visual memory, increased the patients’ self-esteem, and reduced anxiety. The second case is a female aged 29, suffering from paranoid schizophrenia. In the clinic picture sleep disorders were dominant, accompanied by deficits of memory and attention. The therapy reduced the anxiety level, improved his sleep, and enhanced cognitive functioning. The third case is a female aged 29, suffering from paranoid schizophrenia.

Results and Conclusion: The therapy significantly improved the functioning of attention and visual working memory. The cognitive changes reduced her autistic symptoms allowing for better social contacts, and reduced anxiety.

Background: The dysbindin (DTNBP1): dystrobravin-binding protein 1) gene has been repeatedly shown to be associated with schizophrenia across diverse populations. A recent study also showed that risk haplotypes were shared with a subgroup of bipolar disorder with psychotic episodes, but not with all cases. It is possible that DTNBP1 confers susceptibility to psychotic symptoms in various psychiatric disorders besides schizophrenia. Methods: Methamphetamine psychosis, the psychotic symptoms of which are close to those observed in schizophrenia, was investigated by case-control association analyses of DTNBP1.

Results: DTNBP1 showed significant associations with methamphetamine psychosis at polymorphisms of SNPA (rs2619538, p=0.049) and P1635 (rs3213207, p=0.00003) and the three-locus haplotype of SNPA-P1635-P1655 (rs2619539, permutation p=0.0005). The A-A-C haplotype, which was identical to the protective haplotype previously reported for schizophrenia and psychotic bipolar disorders, was a protective factor (p=0.0013, OR=0.62, 95% CI 0.51-0.77) for methamphetamine psychosis. The T-G-C haplotype was a risk for methamphetamine psychosis (p=0.0012, OR=1.49, 95% CI 1.3-1.64).

Conclusions: Our genetic evidence supports a possibility that DTNBP1 is involved in psychotic liability for not only schizophrenia but also other psychotic disorders, including substance-induced psychosis.

3. Richard D. Camacho2, Dr., MD, rcd0627@yahoo.com

Objective: While many studies suggest a high prevalence of diabetes in patients taking atypical antipsychotic medications, less is known about pre-diabetes, defined as fasting plasma glucose=100-125 mg/dl or oral glucose tolerance test=140-199 mg/dl. Management of pre-diabetes may be important in preventing more serious health problems. This study examines the prevalence of pre-diabetes and its relationship to other risk factors for cardiac morbidity and mortality in patients taking atypical antipsychotic medications.

Methods: Subjects underwent fasting glucose laboratory testing, physical measurements, and a demographic and medical history interview. These subjects were matched for age, gender, BMI, ethnicity, and history of diabetes with patients from the 2003-2004 National Health and Nutritional Examination Survey.

Results: The prevalence rates of pre-diabetes, diabetes, hypertriglyceridemia, dyslipidemia, and metabolic syndrome were 29.4%, 21.4%, 46.8%, 84.9%, and 61.1%, respectively, n=126. The prevalence rates for diabetes, dyslipidemia, and metabolic syndrome were statistically different between our group and the control, but not for pre-diabetes and hypertriglyceridemia. There were no significant correlations between pre-diabetes and hypertriglyceridemia, low HDL, metabolic syndrome, or BMI in our patients.

Conclusions: Nearly one-third of our patients had pre-diabetes and may have appeared asymptomatic. Further study is needed to better understand the role of pre-diabetes as a precursor to diabetes in this patient population and the impact its treatment may have on its course.

FAMILY THERAPY FOR A FAMILY OF FATHER AND SON WITH ASPERGER’S DISORDER

INSTITUTIONS
1. Department of Psychiatry, Yun-Lin Branch, National Taiwan University Hospital, Taiwan Republic of China
2. Department of Psychiatry, National Taiwan University Hospital, Taiwan Republic of China

AUTHORS
1. Shu-Tsen Liu1
2. Huey-Ling Chiang2
3. Yen-Nan Chiu2

Aim: To work with the family to face the difficulty of empathy
Case report: The initial target client was the little son, who was accompanied by his burnt-out mother to visit our child psychiatric clinic for his attacking his mother. However, he expressed his worries about the more severe conflicts between his parents and between his elder brother and his father. The elder brother was diagnosed asperger’s disorder previously, but the family denied this. The mother felt frustrated about the difficult communication with the father, and her elder son “acceded” her anger toward her husband, attacking the father agitatedly for his rigid moral rules, and didn’t respect his father for his incompetence, not-intervening attitude in family conflicts. In family therapy, we adopted the concept that “Chinese men are blunt, and transmitted his love to his family only by working hard” instead of the term of “Asperger’s disorder” to help the mother and the children to understand the father’s love for them. We supported the father not to hide himself into his abstruse interests in conflicts and to see the meaning of these conflicts.

Discussion: The concept of gender difference of communication in the Chinese culture may help the family to empathize the deficit of ability of empathy. Therapists need help the family to explore the hidden message to be communicated in conflicts, to support the one with Asperger’s disorder and his difficulties in social skills and verbal communication, and to reconstruct their rigid believes.

Aim: Although previous western studies have demonstrated cognitive deficits in children with epilepsy, particularly, attention deficit, only some were conducted in normally intellectual children with epilepsy. Our study aimed to investigate the neuropsychological functioning in Taiwanese children with epilepsy and overall normal intelligence.

Methods: The case group consisted of 44 pediatric patients with epilepsy, aged 6-16 (mean ± standard deviation, 9.91±2.52) and 88 age-, sex-, and parental education- matched school controls were selected. Cases with mental retardation or autism were previously excluded. WISC-III and Conners’ Continuous Performance Test were administered. Parents of all participants completed the Child Behavioral Checklist. Linear multi-level model was used for matched analysis.

Results: The average age onset of epilepsy (mean ± SD) was 7.82±3.17 and 38 cases (86.4) were taking anticonvulsants. The average full scale IQ (mean ± SD) of the case group (94.00±13.28) was lower than that of the controls (105.02±10.81) by demonstrating lower Verbal IQ, Performance IQ, Verbal Comprehension, Perceptual Organization, and Freedom from Distractibility (Cohen’s d ranging from 0.54 to 0.94) than the controls. The case group had more severe inattention based on CBCL. There was no group difference in CPT parameters except that the case group had higher response style (p<0.05), indicating a tendency to slowness or caution.

Conclusion: Our findings demonstrate that Taiwanese children and adolescents with epilepsy and overall normal IQ have lower scores in IQ profiles. Although attention problems were reported by their parents, patients with epilepsy did not show attention deficits measured by the Continuous Performance Test.

6. Ivanova A. Svetlana

Methods: 60 patients with dissociative (conversion) disorders (ISD-10, F44), 43 patients with adjustment disorders (ICD-10, F43.2) and 85 mentally healthy persons were investigated. Polymorphic variants of a genes of serotonin receptor 2a (5-htr2a) and serotonin transporter (5-htt) were studied. Cases with mental retardation or autism were previously excluded. WISC-III and Conners’ Continuous Performance Test were administered. Parents of all participants completed the Child Behavioral Checklist. Linear multi-level model was used for matched analysis.

Results: Authentic distinctions between distribution of genotypes A1A1 and A1A2 of locus T102C of gene 5-HTR2A is characteristic for patients with adjustment disorders in comparison with mentally healthy people (X^2=4.26; df=1; p=0.04). We have observed statistically significant distinctions between frequencies of genotypes AG and GG of locus A-1438-G of gene 5-HTR2A at patients with dissociative (conversion) disorders and mentally healthy people (X^2=3.3; df=1; p=0.03). For patients with dissociative (conversion) disorders and adjustment disorders is characteristic the tendency of distinctions of distribution of genotypes of locus VNTR-17 of gene 5-HTT. The distribution of genotypes LL, LS and SS of locus 5’-HTTLPR of gene 5-HTT among patients with dissociative (conversion) disorders did not differ from distribution of these genotypes among patients with adjustment disorders.

Conclusions: The locus T102C of a gene 5-HTR2A are associated with adjustment disorders, the locus A-1438-G are associated with dissociative (conversion) disorders.

Objective: Study concentrations of steroid and thyroid hormones in patients with neurotic, stress-related and somatoform disorders. Methods: 35 patients with dissociative (conversion) disorders (ICD-10, F44), 29 patients with adjustment disorders (ICD-10, F43.2) and 27 mentally healthy persons were investigated. Immunofermental analysis for definition of concentration of steroid and thyroid hormones were carried out.

Results: We have observed statistically significant increase level of cortizol (p<0.05) in patients with adjustment disorders (635.04±48.69 nmol/l) in comparison with control and patients with dissociative (conversion) disorders (444.97±24.53 nmol/l and 443.13±23.00 nmol/l accordingly). The statistically significant lowered maintenance of dehydroepiandrosteronum is characteristic for patients with adjustment disorders in comparison with control and patients of another group (1.65±0.24 pkg/ml; 2.44±0.24 pkg/ml and 2.93±0.36 pkg/ml accordingly, p<0.05). For patients with dissociative (conversion) disorders is characteristic the statistically significant increased level of triiodthyronin (1.71±0.12 nmol/l), in patients with adjustment disorders and mentally healthy persons this metric composed 1.26±0.02 nmol/l and 1.34±0.04 nmol/l accordingly. The level of thyroxin for the persons with dissociative (conversion) disorders differ from values of control and patients with adjustment disorders (23.68±2.07 pkmol/l; 17.64±1.43 pkmol/l and 14.69±0.53 pkmol/l accordingly, p<0.05).

Conclusions: The patients with adjustment disorders is characteristic the statistically significant increased level of cortizol and the lowered maintenance of dehydroepiandrosteronum. Dissociative (conversion) disorders are formed in conditions of the raised maintenance thyroid hormones and the physiological maintenance of steroid hormones.

Schizophrenic patients examined neuropsychologically present cognitive dysfunctions, as far as working memory and executive functions are concerned. RehaCom is a software package, enabling to focus on cognitive areas that need to be trained. According to cognitive disorders connected with prefrontal cortex, present in schizophrenia, there are some reasons that RehaCom could be useful to improve cognitive disorders in these patients. In this study the possibility of cognitive rehabilitation in schizophrenia was examined using computer training program RehaCom in the group of twelve patients. Each patient trained for sixteen sessions with the training programs: attention & concentration and topological memory. This group was compared with control group, that wasn't treated with RehaCom. Patients were randomly given olanzapine, perazine or ziprasidone and their psychopathological status was measured using PANSS. The cognitive functions were checked with TMT, WCST and Stroop in the beginning of experiment and after sixty days. Both groups were randomly selected and didn't show differences in gender, age and illness duration. In concluding examination both groups showed improvement in neuropsychological assessment, but in training group the positive effect of cognitive rehabilitation caused that patients gained better scores in assessment and showed significant improvement in training programs, especially in attention & concentration. Recent researches tendencies are aiming at creating an interdisciplinary schema of treatment for patients with schizophrenia. A comprehensive treatment with cognitive training methods included should show results in increased quality of patient's life.

The recent demonstration of the dopamine (DA) transporter (DAT) in human blood lymphocytes offers the possibility to explore a potential DA marker in an early available tissue. The aim of our study was, therefore, to investigate and compare the DAT in resting lymphocytes of 20 psychotic patients and 20 healthy control subjects, by means of both the binding parameters (Bmax and Kd) of 3H-WIN 35,428, a specific ligand for it, and the reuptake parameters (Vmax and Km) of 3H-DA. The 3H-DA reuptake was performed according to the method of Amenta et al. (2001), with slight modifications. For the binding assay, aliquots of lymphocyte membrane suspensions were incubated with increasing concentrations of 3H-WIN 35,428; the non-specific binding was determined by using DA 10 mM. The Bmax values (mean±SD, fmol/mg protein) of the patients were 21.46±2.12, significantly lower than those of healthy control subjects (38.53±3.21), while the Kd (mean±SD, nM) did not show any change (0.56±0.24 vs 1.21±0.50, respectively). A significant difference was also detected in Vmax (mean±SD, pmol/109cells/min) values which were significantly lower in the patients than in healthy subjects (8.23±1.08 vs 52.92±21.10), while the Km (mean±SD, nM) did not show any change (166.21±76.07 vs 179.42±66.12, respectively). Our data indicates a reduced density of the lymphocyte DAT proteins which function also at a lower velocity, as shown by the decreased Vmax. Taken together, our findings would indicate that psychotic patients present a complex alteration of DAT in lymphocytes, which may reflect alterations of the same structure present in the brain.

PTSD, BRAIN INJURY, AND PSEUDOEPILEPSY

INSTITUTIONS
1. Center “Stress”, Day-Treatment, Yerevan, Armenia

AUTHORS
1. Samvel P. Margaryan1, Dr., MD, PhD, smargarian@yahoo.com

Objective: The research to date suggests: a) PTSD is important in the development of pseudo seizures; b) brain injury increases the risk of PTSD. Very few data is available about the interrelations of PTSD, brain injury and pseudo seizures.

Method: Single case study.

Results: Patient S., 41 years old. At age 28, he saw the death of his wife and son under the ruins of earthquake. He was reserved, but then became rather quiet, and he was married after 4 months. At age 31, he joined volunteer soldiers, was affected by severe psychogenic factors. At age 34 he was wounded associated with serious brain contusion. After the return he developed PTSD, had a strong guilt for the loss of friend, “saw clearly his face”. He became explosive; once he struck heavily his daughter, he had amnesia what had happened. The GP referred him to the Center of Epileptology, where didn’t revealed epilepsy, and diagnosed PTSD. During the inpatient treatment he became quiet, but continued to have periodically seizures on the height of headaches, lasting 3-10 minutes and ending with amnesia and expressed fatigue. He did well only after the antidepressive treatment.

Conclusions: PTSD and pseudo seizures not developed after severe personal misfortune without brain injury, but developed after war distresses and brain contusion. Traumatic brain injury + traumatic stress = pseudo epilepsy? Clearly, this issue warrants prospective longitudinal studies.

Aims/Objectives: The Alzheimer’s disease model on animal experiment is validated through the atropinic cholinergic blockade, the neurodegenerative-type mechanisms being accelerated by hypoxia and vascular ischemia. Cerebrolysin can realize neuroprotection towards hypoxia and ischemia.

Methods: We evaluated the neuroprotective role of Cerebrolysin on animal model (Wistar rat), within the cholinergic blockade with vascular component. We studied 6 lots of 5 male adults rats each (200-250g), held through the study in temperature, humidity, food and ambient stressless conditions, compared to a control lot.

N1 - cholinergic blockade;
N2 - cerebrolysin + cholinergic blockade;
N3 - cerebral ischemia (uni/bilateral carotidian clamping);
N4 - cerebrolysin + cerebral ischemia;
N5 - cerebral ischemia + cholinergic blockade;
N6 - cerebral ischemia + cholinergic blockade + cerebrolysin;
N - control;

A single dose (5ml/kg)/day of Cerebrolysin was administrated 10 days before and 7 days after the cholinergic blockade or cerebral ischemia. The rats were sacrificed during the 18th day, 6 hours after the last administration. The sample brain was histopathologically processed through specific colouring and fixation techniques and we evaluated the neuroprotection comparing the cytoarchitectural changes in frontal cortex and hippocamp and the presence of β-amyloide to optical microscope.

Results: The cholinergic blockade produces cytoarchitectural changes in frontal cortex and hippocamp, the cerebral ischemia amplifies the lesional changes of the cholinergic blockade and the presence of β-amyloide. Cerebrolysin decreases these changes.

Conclusions: In our study, cerebrolysin proves his neuroprotective value over the cholinergic blockade and the ischemic vascular aggression with complementary therapeutical value.

Aims: Vulnerability-stress models suggest that training in specific stress management techniques should yield benefits to those suffering from schizophrenia. This poster communication describes the development and testing of a cognitive-behavioral stress management program for such patients.

Methods: During 9 month, 14 participants with schizophrenia took part in a psycho-educative program based in the “Practical Coping and Empowerment Strategies for people with Psychiatric Disability” (developed in 1994 by the Center of Psychiatric Rehabilitation - Boston University), and in the relaxation principles of Jacobson, Schutz, and Desoille techniques. Standardized measures of stress levels,
coping strategies, psychosocial functioning, attainment of treatment goals, and data regarding hospitalizations were used to assess change over the rehabilitation process.

Results: Significant differences were found between pre and post test evaluation, revealing decrease in stress levels and increase in coping strategies, especially those related with “self-control”, “assuming responsibility” and “positive revaluation”.

Conclusions: It was concluded that training in stress management may provide patients the necessary skills for coping with daily life stressors and reduce the likelihood of relapse.

Background: Abnormal P50 response has been hypothesized to reflect the sensory gating deficit in schizophrenia. Despite the extensive literature concerning the sensory filtering or gating deficit in schizophrenia, no evidence has been provided to test the relationship of the P50 phenomenon with patients’ experiences of perceptual anomalies.

Methods: The sample was comprised of 91 subjects: 23 schizophrenic patients, 24 first-degree relatives and 44 controls underwent P-50 gating measurement and the Spanish versions of the Structured Interview for Assessing Perceptual/attentional Anomalies (SIAPA) was applied to measure the presence of perceptual/attentional.

Results: The schizophrenic groups and first degree relatives had significantly higher frequencies of auditory and visual perceptual/attentional anomalies. Patients and relatives reporting perceptual anomalies exhibited P50 deficits.

Conclusion: The existence of perceptual/attentional/anomalies in non affected relatives suggests the presence of familial association for these symptoms which could be suitable endophenotype for genetics studies.

Animal and human studies have suggested that excitatory amino acid transporter (EAAT)-2, the major subtype of EAAT, is involved in human mental function and behavior. Recently, it has been shown that the -181 A/C polymorphism in the EAAT2 gene promoter affects plasma glutamate concentrations in humans. In the present study, the association of the -181 A/C polymorphism in the EAAT2 gene promoter with personality traits was examined in 575 Japanese healthy volunteers. Personality traits were assessed by the Temperament and Character Inventory, and the EAAT2 polymorphism was detected by a PCR-RFLP method. The scores of reward dependence were significantly (p=0.017) lower in the group with the A allele (A/A and A/C) than in that without this allele (C/C). When males and females were analyzed separately, the significant difference between the two genotype groups was observed in females (p=0.021) but not in males (p=0.364). The present study thus suggests that the -181 A/C polymorphism in the EAAT2 gene promoter affects the personality trait of reward dependence in healthy subjects.

Introduction: Intercital depression can be seen as a comorbid disorder in more than 40% of epilepsy patients. Duration of epilepsy, as well as the type of the seizures can be suitable for development of depressive disorder in many aspects.

Goal: To test relation between depressive disorder in patients with epilepsy, duration of illness and type of seizures.

Material and methods: With prospective, random selected study, we have tested 300 epilepsy patients, with/without depressive affective disorder at the Out patient Department for Epilepsies of Neurology Clinic. All patients answered Beck and Hamilton depression scales.

Results: This research included male patients or 54% of baseline, at the average age of 37.7 years SD = 12.86, as well as female patients at average age of 32.83 years SD = 12.26. Presence of depression is noticed among 34% of patients at the Beck Depression Scale, and 38.9% at the HAMD with the significant difference in presence of severe depression among women. 14% of patients had suicidal ideas. Duration of illnesses longer than 20 years was in 56% of women with the expressed depression, compared to the 42% men’s (p < 0.01). Majority of patients had partial seizures with/without secondary generalization, and among them partial complex symptoms was significantly more present among females (p<0.01).

Conclusion: Depressive disorder occurs significantly more often among women with the longer epilepsy duration. Epileptic seizures with the partial complex symptoms with/without secondary generalization among women are important predisposing factor for the development of depression.

Key words: epilepsy, depression, duration of epilepsy, type of seizures

Aims/Objectives: Obsessive-compulsive disorder (OCD) is a psychiatric manifestation to which immunological mechanisms have been hypothesized. Tumor necrosis factor alpha (TNF-alpha) is a proinflammatory cytokine involved in RF and several autoimmune diseases. Polymorphisms of the promoter region of the TNF alpha gene have been associated with clinical forms of RF. The nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor-like 1 (NFKBIL1) is suggested as a putative inhibitor of NFkB, modulating the immunological system. Thus, the aim of the present study was to evaluate polymorphisms of the TNF-alpha and NFKBIL1 genes as risk factors for OCD.

Methods: The allelic and genotypic frequencies of -62A/T NFKBIL1 (rs2071592) polymorphism, and -308G/A (rs1800629) and -238G/A (rs361525) TNF-alpha polymorphisms were compared between 111 patients who fulfilled DSM-IV criteria for OCD and 365 healthy subjects.

Results: There was a statistically significant association between OCD and the G allele of the TNF-238 when comparing OCD patients with controls: allelic ($\chi^2=20.79$, p=0.000005, 1d.f.) and genotypic ($\chi^2=15.73$, p=0.0003, 2d.f.) distributions. There was a trend to a significant difference in the allelic ($\chi^2=3.84$, p=0.05, 1d.f.) and genotypic ($\chi^2=3.77$, p=0.15, 2d.f.) distributions of the TNF-308 polymorphism. Regarding the -62A/T NFKBIL1 polymorphism, there were no statistical differences in the allelic ($\chi^2=0.01$, p=0.90, 1d.f.) and genotypic ($\chi^2=0.55$, p=0.75, 2d.f.) distributions between OCD patients and controls.

Conclusion: TNF-alpha may be a susceptibility locus for OCD in this group. More studies with larger samples and ethnicity stratification are necessary to confirm these findings.

Introduction
The phenomenon of excessive internet use (EIU) as a distinct entity within the field of addictive disorders continues to be the subject of debate. Increased activity of brain regions along the central gyrus has been reported in many cue related functional brain imaging studies in drug dependent persons. We hypothesized that the extent of internet use would be associated with altered connectivity of frontal lobe circuits, especially central and cingulate regions that have been adversely affected by substance use.

Methods
18 healthy male adults were first screened using self-report questionnaires and Young's Internet Addiction Scale (YIAS). All subjects were internet users but did not meet criteria for addiction (YIAS <40) enrolled at Bentley College. Diagnostic MRI and diffusion tensor imaging (DTI) data were acquired using a 3 Tesla Siemens Trio MR scanner.

Results
In a voxel-based fractional anisotropy (FA) value analysis including 18 subjects, a significant association was identified in two clusters of left frontal lobe white matter (precentral and postcentral regions). In an analysis of correlation between clusters and Young's internet addiction scale scores (YIAS), craving was negatively correlated with the FA values of the left frontal lobe regions.

Discussions
The current findings suggest that elevated levels of internet use are associated with impaired connectivity (lower FA) of pre and post central areas which respond to both motor and sensory stimulation. The extent to which impaired frontal lobe connectivity is a risk factor for excessive internet use requires further study.

Sydenham’s chorea (SC) is one of the major criteria for the diagnosis of rheumatic fever (RF) and affect 10 and 30% of individuals with RF. That is characterized by emotional lability, uncoordinated and involuntary movements and weakness. Some psychiatric symptoms, as obsessive compulsive behavior or tics, might happen in association with the classical symptoms. A Tumas et al. (2007) study shown that patients with chorea diagnosis have already behavioral abnormalities (40%), dysarthria (38%) and gait abnormalities (34%). A family history is usually positive for RF suggesting some familiar susceptibility to develop RF and SC. Twin studies confirm a familial character since they shown higher concordance rate among monozygotic twins than in a group of dizygotic twins. Recently the interest in pathogenical studies of SC has been increased motivated by the fact that SC might have a common mechanism with Tourette Syndrome, Attention Deficit hyperactivity disorder and other neuropsychopathologies. In order to identify factors that might underlie an individual susceptibility to SC and other neuropsychiatric disorders, in this study we investigated the association between Ser9Gly polymorphism of DRD3 gene and Sydenham's chorea. We genotyped 91 patients and controls for Ser9Gly polymorphism. No association was found between Sydenham Chorea and DRD3 Ser9Gly polymorphism. However our data is preliminary and our sample still with few patients being in our point of view this study should be extended in terms of sample size and number of genes studied.

Object of our research is conducting of analysis of post-stroke disability in Uzbekistan over a period of 1996 - 2005, study of structure and dynamics of disease incidence, as well as detection of causal factors of invalidism of population as a result of these pathologies. Indices of disability after stroke in different regions, according to integrated data of statistical reports of National Centre for Rehabilitation of Uzbekistan over a period of 1996 - 2005, were used as materials for investigation.

Results have shown, that primary disablement because of stroke in all regions tend to increase. So, it made about 3.6 in 10,000 of population in 2005, while it was 1.9 in 1996. Invalidism, as a result of stroke, rises approximately by 89.5% over past 10 years. Indices of residual disability because of cerebrovascular pathology vary from 2.2 to 6.1 in 10,000 of population in different regions of Republic. Based on our data, hypertensive disease and combination of atherosclerosis and arterial hypertension occupy high position (74.6%) in the structure of etiologic factors of stroke. Decree of severity of functional disorders of men is evident to greater extent than women. People 45-60 years old, who has vast working experience and high qualification, become invalids approximately in 80% of cases, and in 20% of cases - pension age people. Our studies have shown, that heavier disability group - I or II - was determined at persons not registered in dispensary, and these groups of patients were permanently disabled or were in need of constant outside care.

AIMS: Punitive parenting, traditionally present in patriarchal cultural environments, shows different socio-demographic correlations in different societies. There is no much evidence on direct relationship between the components of family functioning and the use of punitive measures. The aim of this study was to investigate the socio-demographic and family related correlates of punitive discipline used by Serbian parents.

METHODS: Sixty six parents (30 males, 36 females, age 45.92±8.79 yrs, dominantly urban) completed the following instruments: 1) the general questionnaire (socio-demographic data, including items on self-evaluation of family and partner relations quality); 2) the punitive discipline self-report measure, and 3) Family Adaptability and Cohesion Evaluation Scale (FACES III).

RESULTS: Mean value of punitive discipline score among parents was under the scale midpoint and it did not differ between genders. Significant correlates of the punitive discipline in the general sample were age (r=-0.271, p=0.032), number of children (r=0.261, p=0.044), and number of marriages (r=0.284, p=0.025). The frequent use of punitive discipline was related to younger fathers (r=-0.330, p=0.037), with better family income (r=0.325, p=0.04), more children (r=0.421, p=0.023) and only one marriage (r=-0.312, p=0.047); among females, it was related to less educated participants (r=-0.369, p=0.035), belonging to lower economic strata (r=-0.492, p=0.005). Poor family cohesion among mothers showed a significant relationship with the frequent use of punitive measures (r=-0.390, p=0.025).

CONCLUSION: The study findings may imply that interventions on parental discipline practices should be directed to the specific socio-demographic profiles, and ought to involve family cohesion strengthening measures.

Aims
Although there is growing evidence that Stressful Life Events (SLEs) are associated with exacerbations in Multiple Sclerosis (MS), the nature of this relationship remain unclear. The aim of this study was to examine the interactions between particular types of SLEs and exacerbations in MS.

Methods
Twenty six ambulating women with relapsing-remitting MS were followed for a mean of 56.3 weeks. Each week patients assessed SLEs in self reported weekly diaries that were collected at regular visits every 4 weeks. Neurological examination was performed, by the same neurologist, at baseline and at every regular and additional visit after a suspect exacerbation. For study a possible relation between the type/source of stress and MS relapses, SLEs were grouped together in 6 categories: parents/family, social, work/financial, marital/love relationships, health and related problems, living circumstances.

Results
A Cox univariate regression analysis showed that effects of stress on MS exacerbations was dose dependent. Three or more SLEs were associated with 5.3 times (95% CI 1.7 to 16.4, =0.003) respectively the rate of relapsing during the following four weeks. The type of stressor seemed to have no impact on the association between SLEs and subsequent relapses (chi-square test, $X^2=7.29$, df= 5, p>0.05).

Conclusion
SLEs may be a potential trigger of MS exacerbation. Ambulate women with relapsing-remitting MS with more cumulative SLEs may be at greater risk for a relapse. Particular types of stressful situations have not been shown to be predictive of exacerbations in MS.

Aims: Schizophrenia is a complex mental illness, which is stressful not only for the patients but also for their families. The purpose of this study was to investigate the Quality of Life (QOL) and Sense of Coherence (SOC) of family caregivers of relatives with schizophrenia.

Method: A total of 34 family caregivers (21 mothers, 3 fathers, 8 adult siblings, and 2 spouses) of schizophrenic patients, aged from 27 to 88 years old participated in the study. The mean age of the caregivers was 63.7±13.3 years old. Two questionnaires were used to assess the subjective quality of life and the ability to cope with stress and health issues: a Japanese version of the WHOQOL-26 scale and the SOC-13 scale. Results: In the category of sense of meaningfulness, the female subjects scored higher than male subjects, although the difference was not significant. The score of the environmental dimension in the subjects aged 60-80 was higher than those aged 20-50 (p<0.05). There were significant correlations between sense of comprehensibility and environmental dimension(r=0.56, p<0.01), sense of meaningfulness and environmental dimension(r=0.58,p<0.01)and sense of manageability and social dimension(r=0.49,p<0.01).

Conclusion: It was suggested that attitudes and feelings of family caregivers toward schizophrenic patients were related to their sense of coherence. Also, SOC should be considered for family caregivers to promote the environmental and social dimensions in QOL.

Eastern Europe immigrant populations are a recent migratory flow in Portugal, with socio-demographic, cultural, linguistic specificities in face of the Portuguese population that represent a new challenge to structured health services and mental health care in Portugal.

This study aims to perform a socio-demographic characterization, identify the main health problems and health surveillance patterns of the immigrant population from Eastern Europe countries in Portugal. It also aimed to assess the mental health status of this population and its vulnerability, relating them with the migratory process, access to health services and social support.

The study was conducted in immigrant community centers from January 2005 to March 2006 and focused on 566 Eastern Europe immigrants in Portugal, 296 males and 270 females, using the GHQ-28 (Goldberg & Hillier, 1979); the SSQ6 (Sarason, Sarason & Pierce, 1987) and a Socio-demographic questionnaire.

From the 566 individuals of the sample we conclude that this population is predominantly from the male gender, in active young age, characteristic of an economic migration, with high academic qualifications. A significant percentage of the inquired refers consumption of alcoholic drinks and tobacco, have risk work tasks and presents reduced health surveillance behaviors. 10.4% of the inquired immigrants presented psychiatric pathology assessed by the GHQ-28 and low social support. The statistic analysis revealed the existence of relations between social support and mental health, access to health services and the levels of mental health.

IDENTIFICATION OF THE CYP2C19 GENE *17 ALLELE IN A LARGE CLINICAL TRIAL OF CITALOPRAM

INSTITUTIONS
1. Mayo Clinic, Rochester, United States

AUTHORS
1. David A. Mrazek, M.D., F.R.C. Psych
2. John L. Black, M.D.
3. Dennis J. O’Kane, Ph.D.
4. Maureen S. Drews, B.S.

8. Richard M. Weinshilboum, M.D.

Background: A common novel CYP2C19 gene variant is believed to cause ultrarapid drug metabolism of proton pump inhibitors and antidepressants. Results suggest the CYP2C19*17 allele effects serum concentrations and could possibly explain therapeutic failure of commonly used antidepressants, such as citalopram and escitalopram. Subjects in level one of the Sequenced Treatment Alternatives to Relieve Depression (STAR*D) study were treated for major depressive disorder with citalopram. This study examines the clinical significance of the CYP2C19*17 allele by genotyping the STAR*D sample for *17 and assessing treatment outcome.

Methods: Original genotyping of STAR*D subjects did not test for the SNP defining the *17 allele. The novel 806C>T polymorphism that differentiates these alleles has been genotyped in 718 of the 1914 subjects. Genotyping is still underway.

Results: Since genotyping originally did not differentiate between *1 and *17 alleles, frequency of the *1 allele was originally thought to be 84.1%. Genotyping of the novel 806C>T polymorphism which defines the *17 allele, revealed a frequency of 20.2% for this new allele, thus dropping the *1 allele frequency to 63.9%. Remission rates in subjects with the *17 allele will be analyzed upon completion of genotyping.

Conclusions: Previous pharmacogenomic studies of the CYP2C19 gene have not identified the *17 allele. This may have implications for the interpretation of their results given that a large number of subjects with more rapid metabolism were not identified.

Gender identity disorder (GID) is a disease characterized by a disagreement between objective born sex and subjective gender identification.

Recently its possible biological underpinnings have become a topic of examination but the etiology of GID remains unclear at present. This study is the first trial to evaluate the regional cerebral blood flow (rCBF) of GID. We compared the rCBF of 12 GID patients to that of normal control subjects using Statistical Parametric Mapping (SPM) analysis of Single photon emission computed tomography (SPECT). All subjects did not have any kind of regular medication including psychotropic drugs and did not have any kind of physical or psychiatric comorbidity. Magnetic resonance images (MRI) of all subjects were examined and revealed no mass lesions or any structural abnormality of the brain. The GID group and the normal control group were well matched in age, hand preference, Self-Rating Depression Scale (SDS) score and State-Trait Anxiety Inventory (STAI) score. All subjects were required to provide written informed consent to any study-related procedures. The study protocol was approved by the ethics committee of Fukuoka University Hospital and carried out from September 2006 to December 2007. In the end, the GID group showed a significant decrease of rCBF in the left medial frontal gyrus, the left superior frontal gyrus and the left cingulate gyrus. A possible biological etiology of GID is suggested.

A CASE ILLUSTRATING THE CLINICAL UTILITY OF CYTOCHROME P450 GENOTYPING

INSTITUTIONS
1. University of California, Irvine, Psychiatry, Orange, CA, United States

AUTHORS
1. Brenda L Jensen¹, Dr., MD, bjensen@uci.edu
2. Gerald A Maguire¹, Dr., MD, gamaguir@uci.edu
3. Charles T Nguyen¹, Dr., MD, tuantun@uci.edu

Introduction:
In this case report we analyze whether cytochrome (CYP) 2D6 poor metabolism induced medication toxicity.

Case Report:
An 18 y/o Latino male with schizophrenia was admitted for extreme restlessness and agitation after taking risperidone 3mg following several days of noncompliance. Patient was restarted on his previous dose of risperidone 3mg BID. On hospital day 4, he became increasingly agitated, requiring IM injections of haloperidol 10mg and diphenhydramine 100mg. On day 5, he threw chairs and was given haloperidol 5mg IM and diphenhydramine 25mg IM. On day 6, the patient developed extreme restlessness, generalized muscle contractions, a pulse of 136, temperature of 37.5 C, CPK level of 3655 U/L and systolic blood pressure from 90-160. Cytochrome P450 genotyping results showed the patient was a poor metabolizer of CYP2D6 with both alleles deleted. Risperidone and haloperidol were discontinued and olanzapine and valproic acid were initiated. He responded well to these medications and maintained stable vital signs without dystonia or akathisia.

Discussion:
Dystonia, akathisia and vital sign lability are associated with risperidone and haloperidol toxicity. Both medications are extensively metabolized by CYP2D6, an enzyme completely lacking in this patient. Upon switching to medications not metabolized by CYP2D6, the patient’s symptoms resolved.

Conclusion:
Toxicity of psychotropic medications may occur with CYP2D6 poor metabolism. Genetic testing can identify individuals with poor metabolism and allow physicians to adjust medications accordingly.

3. Taiwo O Odugwu¹, Dr, MBBS, odug2@yahoo.com
4. Dipo O Adepoju¹, Dr, MBBS, ejadipso@yahoo.com

AIM/OBJECTIVE: To compare the profile of patients with schizophrenia and mood disorder presenting with catatonia.

METHOD: Cases in which presentation of catatonia was noted at the Psychiatric Hospital, Yaba, Lagos, Nigeria were reviewed over two time frames, 1983-85 and 2003-05. Socio-demographic and clinical features were described for each diagnosis.

RESULTS: There were a total of 98 cases of which 40 were seen between 1983-85 and 58 between 2003-05. Schizophrenia accounted for 82.5% and 53.4% in the two periods, while the proportion associated with mood disorders increased from 10% to 20.7%. Male to female ratio was 1.2:1 in schizophrenia and 1:3 in mood disorder. 81% and 68.8% respectively of those with schizophrenia and mood disorder were single, while 59.3% and 37.4% were unemployed. 16.7% and 12.5% had comorbidities. Electroconvulsive therapy was used in 12.5% of schizophrenia and 31.3% of mood disorder cases.

CONCLUSION: The proportion of catatonia cases associated with mood disorder has increased over the years. More females with mood disorder are likely to present with catatonia. Electroconvulsive therapy was also more likely to be used in mood disorder.

Recently, several studies have shown that the combined effects of a number of candidate gene variants and an adverse environment interact in a synergistic fashion, i.e., differing from merely addition, e.g., with regard to an MAOA polymorphism x environment and risk for antisocial behavior and a 5-HTT polymorphism x environment and risk for depressive episodes. As expected, usually homozygotes for the gene allele under study showed the strongest effects with heterozygotes in between. Rarely have sexual dimorphisms been noted. Furthermore, gene-gene interactions are likely to be present with regard to most phenotypes with a polygenic background, such as personality and other complex behaviors, but so far there are few studies demonstrating this phenomenon.

RESULTS:
1. Obvious sex differences - even going into the opposite directions have been found with regard to phenotypic expression, e.g., with regard to 5-HTTLPR x environment and depression, with regard to MAOA VNTR x environment and various forms of antisocial behavior (1) and with AP2B x environment and depression.
2. Marked heterosis effects (homozygotes showing the strongest effect) have been noted with regard to 5-HTTLPR x environment and alcohol intake and smoking.
3. Clear epistasis effects (gene-gene interactions) have been found e.g., between the 5-HTTLPR and a polymorphism of the AP2B gene on Cloninger’s Temperament and Character Inventory (TCI) (2), as well as between a tryptophan hydroxylase 2 polymorphism and the 5-HTTLPR on amygdala response (PET) on emotional stimuli.

BACKGROUND: Psychogenic polydipsia and associated hyponatremia have been well-documented in patients with schizophrenia, as well as other psychiatric populations, including individuals with bipolar disorder. There have been reports of improvement of this condition with clozapine in the schizophrenic population; while to our knowledge, no reports of experience with this agent in the polydipsic bipolar patients has come out.

CASE: A 47-year old female patient with bipolar disease presented with repeated attacks of clouding of sensorium and delirium associated with severe hyponatremia. She had bouts of polydipsia (consumption of fluids up to 10 litres daily) in the previous 6 months, and had been hospitalized several times for attacks of hyponatremia-associated CNS complications (seizures, delirium and coma). The patient did not cooperate with ordinary measures of fluid restriction, and was unresponsive to a short trial of beta-blocker propranolol for the treatment of polydipsia. Only after administration of clozapine did the patient's polydipsic behaviour improve dramatically. And at the 6th month of follow-up, she was still free of polydipsia.

CONCLUSION: Clozapine might be a good option for treatment of psychogenic polydipsia in patients with bipolar disease.

The patient is a 31 year old single unemployed overweight woman with learning disabilities. She came to the psychiatric outpatient's with paranoid persecutory delusions and violent outbursts towards family members. She was diagnosed at the age of four as suffering from translocation between short arms of chromosome 2 and the long arms of chromosome X [46, XX, t(2;X) (p23; q21)]. Her parent's caryotype was normal. Physical examination revealed high forehead, low set ears, hypertelorism, broad nasal bridge and macrostomy. Pelvic ultrasound revealed hypoplastic uterus and ovaries. The patient was on contraceptives. Neurological examination revealed no focal lesions. Blood test revealed no abnormalities and the thyroid function was within normal limits. She responded well on topiramate 100 mgr and citalopram 20 mgr. After two months she was less violent and did not express any persecutory ideation. This is a rare case of genetic mutation and is presented in order to highlight the association of the genotype with the patient's phenotype.

GENERAL HEALTH AND DEFENCE MECHANISMS IN THE YOUNG ADULTS FROM THE FAMILIES WITH MENTAL HEALTH PROBLEMS

INSTITUTIONS
1. INSTITUTE OF PSYCHIATRY AND NEUROLOGY, IV CLINIC OF PSYCHIATRY, WARSAWA, Poland

AUTHORS
1. Jolanta Paszko, Dr, jp232@interia.pl
2. Maria Zaluska

Introduction: community care is enabling mentally ill persons to undertake parental roles. The children of mentally ill parents are poorly recognised group, with unmet needs, and at risk of health and adjustment difficulties, caused by genetic and psychosocial load. The aim: to measure general health, and defence mechanisms in the young adults growing up in the families with parental schizophrenia in comparison with the healthy families, and the families with parental alcohol problems.

The method: Three groups consisting each one of 32 to 35 young people between 18 and 35, being grown up in the families with parental schizophrenia (A), parental alcohol problems (B), and healthy parents (C) were interviewed and investigated with the General Health Questionnaire GHQ-28, and DSQ-40 questionnaire for defence mechanisms.

Results: 15.6% in the group A, 14.3 % in the B and 3.1 % in C have had recently seeking psychiatric or psychological help. The groups differed significantly in the summarised GHQ measure and in the subscales of somatic symptoms, sleep disturbances, and anxiety, as well as in the level of immature defences in DSQ-40. The highest results were in the group B (alcohol families), differing significantly from the healthy (C) families. The results in the group A-(schizophrenia) were comparable with the B.

Statements: chronic emotional load in families with schizophrenia is comparable with that in alcohol families and is influencing significantly general health and emotional development of offspring.

STUDENTS COPE WITH STRESS LONG AFTER A NATURAL DISASTER STRIKES

INSTITUTIONS
1. University of Louisiana at Lafayette, Nursing, Lafayette, LA, United States

AUTHORS
1. Ardith L. Sudduth, PhD, als0524@louisiana.edu

Objective: The objective of this study was to explore how nursing students were coping with the stressors associated with two natural disasters occurring nine months prior to the study. It has been observed that many individuals will experience symptoms of Post Traumatic Stress Disorder (PTSD) after a traumatic stress event such as natural disasters.

Method: Student nurses voluntarily completed a standardized post traumatic check (PCL-C) list and open ended questions asking about their lived experiences.

Results: Students shared their lived experiences and many reported feeling frustrated, angry, and depressed. They also continued to worry about the health and welfare of their families who lost property and jobs due to the hurricanes. Nearly 30% (n=383) of the students completing the survey were exhibiting symptoms of Post Traumatic Stress Disorder nine months after the disasters. All of the symptoms on the standardized PCL-C scale were highly significant (p=.01). Symptoms of difficulty concentrating, feeling angry, flashbacks, and feeling upset were the most common and those that interfere with learning. Coping mechanisms frequently helpful were the church, family, and friends.

Conclusion: Stress among students continued well after the cleanup process for natural disasters had been implemented and much of the community had moved on. Educational institutions need to be very much aware of the stress and PTSD symptoms experienced by students attempting to complete rigorous academic requirements.

3. Dusica Lecic Tosevski³, Prof. Dr, PhD
4. Oliver Toskovic¹

**Objectives:** Burnout is a syndrome consisting of physical and emotional exhaustion resulting from negative self-concept, negative job attitudes, and loss of concern for clients. The objective of this study was to assess and compare expressiveness of three dimensions of burnout in judges dealing with war crimes.

**Methods:** The sample consisted of the highly homogeneous group of war crimes chamber judges, Belgrade District Court and deputy war crimes prosecutor of the Republic of Serbia, as the only representatives of judiciary to prosecute all war crimes committed on the territory of the whole former Yugoslavia. Assessment has been carried out by the Maslach Burnout Inventory.

**Results:** There were significant differences between three different dimensions of the burnout. The lack of personal accomplishment was the most prominent dimension with very high score, dimension of emotional exhaustion was moderate and dimension of depersonalization with the lowest expressiveness.

**Conclusions:** Having in mind potential long-term effects of the burnout phenomenon, it is highly important to further explore the correlation between this syndrome and various variables, such as age, personality factors, job satisfaction and organizational characteristics and compare this group with the same profile group which works under more favourable conditions.

WHICH MEDICAL SPECIALTY BURNS OUT THE MOST?

**INSTITUTIONS**
1. Institute of Mental Health, Belgrade, Serbia and Montenegro

**AUTHORS**
1. Bojana Pejuskovic¹, Dr, bpejuskovic@eunet.yu
2. Dusica Lecic Tosevski³, Prof. Dr, PhD
3. Oliver Toskovic¹

**Objectives:** Burnout syndrome and stress-related disorders are increasing among medical specialists. It has been suggested that some kind of specialty health workers are prone to the burnout more than others. The objectives of this study were the following: 1) to assess difference between intensity of the burnout syndrome among three different specialties - general practitioners, psychiatrists and surgeons; 2) to assess and compare expressiveness of the dimensions of burnout in these groups.

**Methods:** The sample consisted of 150 physicians (50 general practitioners, 50 psychiatrists and 50 surgeons). Assessment has been carried out by the Maslach Burnout Inventory.

**Results:** The score of the burnout syndrome was moderate in all three examined groups. However, there were significant differences between the three groups of specialists. Dimension of emotional exhaustion was the most prominent in general practitioners, dimension of depersonalization in surgeons, and the lack of personal accomplishment was the lowest in general practitioners.

**Conclusions:** Since the burnout syndrome affects personal well-being and professional performance it is important to undertake preventive measures against its development, such as strategies focused on individual and organization.

BURNOUT IN ANESTHESIOLOGISTS AT A UNIVERSITY HOSPITAL IN BELGRADE

INSTITUTIONS
1. Institute of mental health, School of Medicine, Belgrade, Serbia and Montenegro

AUTHORS
1. Natasa Petrovic Stefanovic¹, Mrs., sterod@eunet.yu
2. Ivana Perunicic¹, Mrs, perunicic@eunet.yu
3. Dusica Lecic Tosevski¹, Dr., MD,PhD, dusica.lecic.tosevski@eunet.yu

Aims/Objectives: Few studies have been published on burnout in anesthesiology even though this specialty is considered particularly stressful. Burnout syndrome, characterized by emotional exaustion, depersonalization and lowered sence of professional accomplishment is a frequent consequence of chronic stress. The aim was to assess the prevalence of burnout syndrome in anesthesiologists.

Methods: The sample consisted of 46 anesthesiologists from a university hospital in Belgrade. The burnout was assessed using Maslach Burnout Inventory, which addresses three general scales-emotional exhaustion, depersonalization and reduced personal accomplishment.

Results: Our results indicate that burnout is highly prevalent among anesthesiologists. We detected high levels of emotional exhaustion in 65.6% of them and of depersonalization in 37%.The scores reflecting low levels of sense of personal accomplishment were recorded in 100% of the sample.

Conclusions: Our findings are in accordance to other authors. The burnout syndrome is frequent among health workers,especially among those with high work demand, such as anesthesiologists. The awareness of the problem should be highlighted and programs need to be put in place to reduce the risk of developing this syndrome.

MENTAL ILLNESS: EXERCITATION, WITHOUT CONSCIOUSNESS NOR BRAKE, OF A CONDITIONAL INERTIA

INSTITUTIONS
1. CENTRO DE INVESTIGACIÓN, DIFUSION Y PROMOCION DE LA LIBERTAD INTERIOR (CIPLI), United States

AUTHORS
1. Christian Phillips¹

Objective: Demonstrate that Mental Illness is the mechanical practice, stylization and sophistication of a Conditional Inertia instituted at home.

Method: Analysis and record of those animus states produced in the real I search, during 3 decades.

Results: After delivery the progenitors, having as base punishment and recompense, imposing an antagonistic law to the native one - in which Everything will have been in function of his requirements- , they turn into the principal elements in children existence, who, renouncing to his intrinsic needs, only will execute allowed things, being exposed to punishment for transgression. This, repeated and reinforced in society, establishes a conventional pattern of conduct that only will enter in tautness, with explosion of undecipherable internal conflicts when, the Man, propelled by his inextinguishable Natural Inertia, he searches Himself.

Conclusion: The Man is product of the tension of both inertias, the adapting need will lead him to continue exercising the renunciation to the Being, perfecting the recompense: The Religion; but, if in that progenitor position the Man might place a particular element, ‘This’, aberrantly receiving considerations ‘as of progenitor’, in internal conflicts will have regressed him, perfecting individually the punishment: The Mental Illness.

At present, a study in patients treated at Psychiatric Clinic of Faculty Hospital in Pilsen is carried out.

Objective: To determine whether 10-week treatment with systematic dynamic psychotherapy in an out-patient ward has an influence on heart rate variability (HRV) in patients suffering from neurotic disorders.

Methods: The patients are measured HRV exactly before and after 10 weeks of psychotherapeutic treatment. HRV is measured using the device “TESLAGRAF” at standard conditions. Spectral analysis and other properties of HRV are evaluated.

Results: The preliminary results show a positive outcome of the influence of psychotherapy on the autonomic nervous system.

P-02-281
THE FIGURE OF MOTHER IN FAMILY CONTEXT OF PEOPLE WITH NEUROTIC AND PSYCHOTIC DISORDERS

INSTITUTIONS
1. Moscow Research Institute of Psychiatry, Russian Federation

AUTHORS
1. Victoria Praznova¹, Mrs., MD, otklik-vik@mail.ru
2. Tatiana Zelenkova¹, Mrs, PhD, otklik-vik@mail.ru

To a large extent the family context of a patient is determined by the figure of Mother, who should assume responsibility for caring for the ill and maintain the family relationships. The aim of the study was to make a comparative analysis of individual and household behavior of mothers of adult patients suffering from psychotic or neurotic disorders.

Methods: individual typological questionnaire (L. Sobczyk); questionnaire of intensity of psychological protection (Plutchik-Kellerman-Conte); scales of psychopathological symptomatology SCL-90-R STDs; questionnaire of types of family education (V. Yustitskis, G. E. Eydemiller). Objectivity of conclusions provided by statistic methods: Student t-test, Pearson correlation analysis and Kendall non-parametric X² criterion test.

Analysis of the results has revealed statistically significant differences (p<0.01) of individual peculiarities of mothers of both groups by the following parameters. In the group of mothers of patients with disorders of psychotic level we can observe: high tension of reactive formation in system of psychological protection; the combination of highly expressed divergent identities trends; high level of rigidity. Differences in psychopathological symptoms are expressed in higher rates on the scale somatization, depression, phobic anxiety, paranoid features and by index GSI.

The family behavior of psychotic patients’ mothers is characterized by lack of demands-responsibilities and demands of order and discipline in the family; preference of infantile characteristics; lack of parental feelings; projection of her own unwanted characteristics. The results give grounds for proposing hypotheses of a positive feedback between the level of patients’ mental disease and individual-personal characteristics which determine mothers’ family behavior.

4. Przemyslaw Dulny, MD

Thyroid dysfunctions are commonly encountered in a variety of psychiatric clinical settings. Psychiatric symptoms include cognitive, affective disorders, and psychosis. This presentation intends to demonstrate, by presenting 2 clinical cases, the importance of the thyroid dysfunctions in psychiatric practice.

The first case presents as a 49-year old woman admitted to psychiatric ward because of severe hypothyroidism presenting as psychotic disorder. It was necessary to use antipsychotic drugs together with administration of thyroid hormone. After 4 weeks hospital treatment all psychiatric symptoms disappeared.

The second case is a 54-year old woman who was treated pastly with hyperthyroidism. She also was admitted to psychiatric ward with acute psychosis and thyreotoxicosis. The patient was free of psychiatric symptoms within 8 weeks treatment with antipsychotic and tyreostatic drugs.

The case are followed by brief discussion of the actual literature describing the relationships between hypothyroidism or hyperthyroidism and psychiatric symptomatology.

6. Wahid Melki1, Mr, MD
7. Zouhair El Hechimi1, Mr, MD

Aims: Previous reports established a link between the advanced paternal age and the increased risk of schizophrenia in the offspring. However, the prognostic value of the advanced paternal age in schizophrenia was not described.

Methods: Sixty patients, i.e. 85.7% of all outpatients with schizophrenia diagnosed since at least five years, agreed to take part in the study, accompanied by at least one member of their family. The mean follow-up since the first contact with a psychiatrist was 14.7 years. The outcome was assigned by the global course of the disease since its onset. It was considered as good when there were few episodes with no symptoms in between and poor when symptoms were continuous and worsening. Otherwise, the outcome was considered as intermediary.

Results: The outcome was good in 8.3% of cases, intermediary in 50% and poor in 41.7%. The father’s age at the patient’s birth was significantly higher when the outcome of the disease was poorer (21.2 years if the outcome was good, 35.5 if it was intermediary and 36.8 if it was poor; p=0.04). Since the advanced paternal age is discussed as a major risk factor for congenital disorders associated with de novo mutations, these results suggest that schizophrenia might be a similar condition.

Conclusion: Advanced paternal age would be associated with more serious phenotypes of schizophrenia. There could be an acceleration of de novo mutations in older fathers and/or a multiplication of the muted sites and genes involved with schizophrenia.

Aims: Some epidemiologic studies suggest a positive correlation between major mental disorders, particularly schizophrenia, and criminality. We aimed to study the frequency, the type, the risk factors and the prognostic value of the acts of violence committed by patients with schizophrenia.

Methods: Sixty patients, i.e. 85.7% of all outpatients with schizophrenia diagnosed since at least five years, were included. The clinical and forensic history was assessed by a semi-structured interview with patients and their family, data from medical files and various rating scales: the global assessment of functioning (GAF), scales of assessment of the positive symptoms and the negative symptoms of schizophrenia (SAPS and SANS) and the clinical global impression scale (CGI).

Results: Twenty eight patients (46.7%) had an aggressive behavior (verbal or physical assault) in family before schizophrenia onset. Aggressiveness was noted as the first prodrome in 13.3% of cases (n=8). Twenty eight acts of major violence were committed by 31% of patients (n=18). Schizophrenia’s onset was announced by an aggressive act in 13.3% of cases (n=8). The majority of acts (n=12) were committed against a familiar person. Eight patients recommitted violent acts. Male gender, minor physical abnormalities, low pre-morbid GAF scores, early onset of schizophrenia, substance abuse and severity of current symptoms were correlated to the aggressive behavior. Only prodromic aggressiveness was associated with a bad outcome of the disease.

Conclusion: Although violence may be committed by patients with schizophrenia, such behavior is attributable to a particular subgroup and does not have necessarily a pejorative prognostic value.

MINOR PHYSICAL ANOMALIES IN SCHIZO-OBSESSIVE DISORDER

INSTITUTIONS
1. Apollo Gleneagles Hospital, Psychiatry, Kolkata, India

AUTHORS
1. Debashis Ray, Dr., mindhealth@gmail.com

Introduction
Emil Kraepelin opined that schizophrenia is caused by a neurodegenerative process. However, the recent consensus is that the underlying etiopathology of schizophrenia is more neurodevelopmental than neurodegenerative. Obsessive compulsive symptoms (OCS) are present in 8-52% of patients with schizophrenia. Evidence that OCS in schizophrenia is a distinct diagnostic entity with clear neurobiological substrates and psychopathology is becoming progressively stronger. Minor Physical Anomalies or Abnormalities (MPA) have been extensively studied in various psychiatric disorders, specially in schizophrenia and obsessive-compulsive disorder. The presence of MPA in a psychiatric disorder is strongly indicative of a neurodevelopmental pathology.

Aim
The present study was aimed to explore the association, if any, between schizo-obsessive disorder and MPA.

Materials and Methods
The study was carried out in Kolkata, West Bengal, India. 100 patients between 18-65 years of age, who met DSM-IV-TR criteria for schizophrenia were included after informed consent was obtained. Patients on clozapine and/or olanzapine, with history of substance abuse, with spina bifida, diabetes insipidus were excluded. Yale-Brown Obsessive Compulsive Scale (YBOCS) and SCID-P-I were employed.

Results and Conclusions
Minor Physical Anomalies were more in the schizo-obsessive group than in patients with schizophrenia without obsessive compulsive symptoms. This difference was statistically significant. This suggests that schizo-obsessive disorder may have an underlying neurodevelopmental etiology and is hypothetically in tandem with earlier studies showing a preponderance of negative symptoms and relatively poorer outcome in schizo-obsessive disorder.

THE QCAE: A QUESTIONNAIRE OF COGNITIVE AND AFFECTIVE EMPATHY

INSTITUTIONS
1. University of Manchester, Psychiatry, Manchester, United Kingdom
2. University of Nottingham, Psychiatry, Nottingham, United Kingdom

AUTHORS
1. Renate LEP Reniers, Miss, MSc, Renate.Reniers@postgrad.manchester.ac.uk
2. Rhiannon Corcoran, Dr., PhD, Rhiannon.Corcoran@nottingham.ac.uk
3. Birgit A Völlm, Dr., MD, PhD, Birgit.Vollm@manchester.ac.uk

Aims/objectives
Empathy is a personality trait that varies in expression in the general population. Cognitive empathy involves the ability to construct a working model of the emotional states of others, whereas affective empathy reflects the ability to be sensitive to and vicariously experience the feelings of others. An increased understanding of empathic behaviour is of great clinical and public-health relevance as a lack of empathy is associated with callous and unemotional behaviour, violence, aggression and criminality, and is related to problems in social communication and interaction, resulting in unstable, impaired relationships.

Methods
A 37-item questionnaire, the Questionnaire of Cognitive and Affective Empathy, has been developed. Principal components analysis revealed five components: perspective taking, online simulation, emotional responsivity, peripheral responsivity and emotional contagion. The first two components represent cognitive empathy whereas the later three comprise affective empathy.

Results
Females showed more empathy than males; they appear better in taking other people’s perspective and simulating the emotional states of others. Furthermore, they seem more sensitive and responsive to other people’s feelings. The cognitive and affective empathy scales and subscales correlated moderately, suggesting a relationship between cognitive and affective empathy but also emphasising the distinction between these two types of empathy. The QCAE showed significant relationships with measures of empathic anger, impulsivity, aggression, psychopathy and Machiavellianism.

Conclusions
The QCAE is a valid tool for assessing cognitive and affective empathy. This new measure quantifies the distinct and specific components that make up cognitive and affective empathy, which in concert, enable empathic experience and behaviour.

Schizophrenia is characterized by a global cognitive impairment, with varying degrees of deficits. Since genetic factors are important in the etiology of the illness, we investigated whether relatives of the schizophrenic patients also show cognitive deficits. In the present study was to examine the processing of facial emotion recognition in schizophrenic patients (N=37) and first degree relatives (N=44) and health adult subject (N= 23). Measure of emotion perception included a facial emotion identification test and event related potential. Study subjects were instructed to respond to a specific target. We used six facial emotion. The identification of negative emotion was poorly in patients than in control. The amplitude of P300 was biggest for fear and happy in schizophrenic patients when comparing to their relatives and controls. This finding are in line with neurobehavioral studies, schizophrenic patients showed greater impairment in the recognition of negative emotions.

Syphilis is a chronic multisystem disease caused by the spirochete Treponema pallidum and is spread venereally or vertically. An estimated 4% to 9% of patients with untreated syphilis develop symptomatic neurosyphilis. Neurosyphilis can be divided in two general categories. The first is early involvement of the CNS limited to the meninges (asymptomatic neurosyphilis, acute syphilitic meningitis and meningovascular syphilis). The second, the late parenchymal forms, includes tabes dorsalis and general paresis. These are extremely rare in the antibiotic era and may present as a mixed, subtle, or incomplete disease. Presenting psychiatric symptoms of general paresis are non-specific and can include personality changes, hostility, confusion, hallucinations, depression or elation and delusions. Symptoms also reported include explosive temper, irritability, emotional lability, unusual giddiness, histrionicity and hypersexuality. This form of chronic meningoencephalitis leads to progressive neuronal loss with subsequent cognitive deterioration. Clinical presentation: We present the clinical report of a 54-year-old man, characterised by sudden development of delusional ideas with grandiosity content, irritability, euphoric mood, aggressive behaviour and total insomnia. The serologic tests (VDRL and TPHA) revealed positive results. The CSF examination demonstrated a reactive VDRL test, pleocytosis and elevated protein concentration.

The patient completed the recommended high-dose intravenous penicillin G course and simultaneously began antipsychotic treatment. Conclusion: The psychopharmacological treatment was not effective in improving psychiatric symptoms, which may be explained by the neurodegenerative nature of this process.

FAMILY BACKGROUND AND GENIUS: NOBEL LAUREATES IN SCIENCE

INSTITUTIONS
1. Harvard, Psychiatry, Cambridge, United States

AUTHORS
1. Albert Rothenberg, Dr., MD, albert_rothenberg@hms.harvard.edu

Aims: The recent Centennial Exhibition, “Cultures of Creativity”, by the Nobel Foundation has focused on the importance of individual creativity in scientific progress. That such creativity is directly inherited has long been a widely held popular and professional belief. The purpose of this study is to assess the hypothesis of direct inheritance of scientific genius and creativity. Methods: Family background data was collected on 435 out of all 488 scientific Nobel laureates (Chemistry, Physics, and Medicine and Physiology) from the beginning year 1901 through 2003. These were compared for incidence of occupational inheritance, i.e., same parent-offspring occupations, with an independently selected matching control group of 548 eminent non-scientists, and for predominant types of occupations with a second independently selected group of 560 longitudinally-followed high IQ non-prizewinners.

Results: Incidence of one or both parents in the same occupation was only 2% for science Nobel laureates but 20% for eminent non-scientists, \( p < 0.001 \). Predominant family background constellation (63%) for science Nobel laureates consisted of the same-sex parent in an occupation involving applied science, technology, or nature-world focus and skills (\( p < 0.001 \) in comparison with the matching group); in both applied type and unrelated occupations, parents manifested lifelong unfulfilled wishes for creative scientific expression and pursuits.

Conclusions: Nobel laureates in the natural sciences do not manifest direct inheritance of creativity from their parents; congruent-gender parents are predominantly in applied occupations and possess lifelong unfulfilled creative wishes. Complex gene expressions interacting with early developmental influences on motivation are suggested.

2. Józef Kocur
3. Paweł Szemraj
4. Janusz Szemraj
5. Aldona Dunicz-Sokolowska
6. Anna Miodek
7. Arkadiusz Jeziorski

Aim: The aim of the paper was the assessment of condensation of interleukina-6 (IL-6) in blood serum at female patients with endogenous depression, malignant breast cancer and groups of patients where these two diseases coexisted.

Method: 119 women were admitted to the research and they were divided into 4 groups: with endogenous depression (N=30), breast cancer (N=30), coexisting depression and breast cancer (N=29) and control group (N=30). Condensation IL-6 in blood serum was marked with ELISA method.

Results: The highest value of condensation IL-6 in blood serum was found in the group with coexisting breast cancer and depression while the lowest value in the control group. The levels of condensation IL-6 in the control group vary significantly statistically \( (p<0.05) \) from remaining groups. The levels of condensation IL-6 in are significantly statistically higher in cases of malignant breast cancer from the group with endogenous depression. The levels of condensation IL-6 in are significantly statistically higher in cases of malignant breast cancer with coexisting depression from the group with endogenous depression and the group with cancer.

Conclusion: On the basis of preliminary results of the research one can state that women with coexisting cancer and depression are particularly subjected to recrudescence or metastasis of cancer process. There exists a strong connection of transition of patients with depression into the group of patients with coexisting breast cancer and depression. Concentration of IL-6 may also be used to diagnose the process of recrudescence of cancer through pre-existing depression dysfunctions.

The purpose of this study is to characterize occipitocerebellar participation in cognitive decline patients.

We investigated asymmetry and functional differences of right and left cerebellum and occipital lobe in non vascular cognitive decline patients with left or right frontal hypoactivity.

Patients and methods:
Twenty brain perfusion studies using ⁹⁹Tc-Etilen Cistein Dimer and 15 Fluor Desoxi Glucose studies were performed in 35 non vascular decline cognitive patients with left or right frontal compromise.

Results: Functional occipital and cerebellum asymmetries were found when frontal hypoactivity asymmetry is present, compared with a normal database.

Conclusions: This results show a trend towards the study of the role of occipitocerebellar areas in cognition decline patients.

AUTHORS
1. Ali Sahraian¹, Dr, MD, barzin_sahraeian@yahoo.com
2. Shima Sahraian¹, Dr, MD, bahredar_.j@yahoo.com

INTRODUCTION: Burnout is a phenomenon in which the cumulative effects of a stressful work environment gradually overwhelm the defences of staff members, forcing them to withdraw psychologically. This study compared the levels of burnout among nurses in different nursing specialties.

MATERIALS & METHODS: The sample of the study consisted of all the nurses working in all public hospitals in Shiraz, Iran who were graduates of either technological educational institutions or universities and had experienced clinical nursing practice for at least 1 year. Using Maslach Burnout Inventory and General Health Questionnaire (28-item version), we identified the psychiatric morbidity and burnout among nurses.

RESULTS: Study results indicated that nurses of psychiatry wards showed significantly higher levels of emotional exhaustion and depersonalization in comparison with nurses working in other wards, and burn wards nurses showed significantly higher levels of personal accomplishment. Also, nurses who were single were more emotionally exhausted.

CONCLUSION: Different clinical working environments appear to have an impact on the development of nurses’ burnout.

**Background**  
Psychotherapy has been shown to be effective in the treatment of mental disorders in the western world but, viewed as an alien method of treatment to Africans.

**Aim**  
To review the literature on the effectiveness of psychotherapy in Sub-Saharan Africa

**Method**  
A systematic search of Medline, Psychinfo, CINHAL, were undertaken along with citation searches, in addition text books and journals were used. Studies were selected if psychotherapy treatment in Africa were described in the title or abstract. Study quality was rated.

**Result**  
The search produced over 1261 articles; 9 met the inclusion criteria, 4 were case reports, 4 randomized controlled trials and 1 quasi-experimental. Of the 5 with relevant data 4 revealed a positive outcome and, the need for some adaptation of the western model.

**Conclusion**  
High quality data examining the effectiveness of psychotherapy is quite sparse however, what few quality data are available revealed mostly positive outcome.

**The epidemiology of adjustment in the expatriate community has not been frequently studied. In September, 2007 we conducted a cross-sectional survey of the entire population of faculty members working for the five US university branches based in Education City (EC), Doha, Qatar on their adjustment to living in Qatar. 'Expatriates' are defined as nationals of one country who for occupational purposes reside in another country, returning home upon completion of work.**

The study aim was to better understand factors involved in expatriate adjustment. Three questionnaires (Demographic, Adjustment Scale (1, 2) and GHQ-12) were used. The 13 question Adjustment Scale has been shown to measure adjustment in several contexts (1,2). Two additional items were added by us to assess ethnocentricity: specifically, "host country world-view" and "socializing with culturally dissimilar expatriates".

From the population of 207 faculty surveyed, 171 questionnaires were returned (response rate 83%). Demographic results will be presented. The Adjustment Scale showed that the average score using the 11 question version was higher (average = 5.2) than the 13 question version (average = 4.4). The addition of the two questions depressed the scores further (average = 3.8). This suggests that difficulties in adjustment experienced by expatriate faculty may have to do with ethnocentricity - the tendency to view one's own culture as correct and evaluating other cultures as wrong. This finding may encourage institutions using expatriate employees to identify strategies towards developing a more tolerant orientation towards host and other expatriate cultures among expatriate employees.

A CASE OF MAYER-ROKITANSKY-KUSTER-HAUSER SYNDROME WITH ACUTE PSYCHOSIS

INTRODUCTION:
Mayer-Rokitansky-Küster-Hauser (MRKH) is a syndrome characterized by Müllerian agenesis (absence of the fallopian tubes, uterus and internal portion of vagina), usually normal female genotype and phenotype, normal secondary sex characteristics and primary amenorrhea. The foregoing is the first case report of a patient psychiatric symptoms and MRKH.

Case Report:
A 21-year-old female patient was admitted to our inpatient psychiatric clinic because of her aggressive, disorganized behavior and incoherent speech, and a rapid decrease of her overall functioning for almost 3 months. Her past and family history was negative for any major psychiatric disorder. Her height was 180 cm and she weighted 55 kilos. Her secondary sexual characteristics (breast development, pubic and axillary hair) were normal on her physical examination. The blood count, standard biochemical parameters, urinalysis and hormone levels (FSH, LH, estrodiol, 17-hidroksiprogesteron, prolactin, testosterone, DHEAS, ACTH, cortisol) levels were within normal range. Her ovaries, tuberian tubes and internal vagina could not be seen and her uterus was found to be hypoplastic at her pelvic USG and pelvic examination. She and her parents did not give consent for explorative laparoscopy. Ductal and glanduler structures were positive according to breast USG. Chromosome analysis revealed a 46-XX karyotype without mozaism. She was given olanzapine 30 mgr/day for 1 month and haloperidole 15 mgr/day for 3 weeks respectively, without any significant clinical response, but showed some clinical improvements (BPRS= 20) with quetiapine 900 mgr/day after 3 weeks.

RESISTING STRESS IN SPORTS OFFICIATING: THE MODERATING ROLE OF POSITIVE PSYCHOLOGY

AIMS/OBJECTIVES: While research has considered the decision making of elite-level collision sports officials, little is known about how these individuals respond to stress. This is somewhat surprising given the attention devoted to understanding the stress encountered by the performers they are officiating. In particular, though recent research has reported on the moderating stress-buffering role of positive psychology in elite-level rugby league footballers, similarly high-achieving rugby league officials have been previously overlooked. The present study is also timely given the newly awarded full-time status of Super League referees. Thus, the purpose of this research was to examine the strategies used by professional rugby league football referees to resist stress.

METHODS: Participants were six male professional referees officiating in Super League, European rugby league’s highest competitive standard. Quantitative measures found all volunteers to be high in stress-buffering positive psychological. Three of the participants subsequently participated in qualitative semi-structured interviews.

HOMOCYSTEINE, FOLATE, VITAMIN B12 AND C677T MTHFR GENE POLYMORPHISM IN TUNISIAN PATIENTS WITH SCHIZOPHRENIA

INSTITUTIONS
1. Al Razi mental health hospital, psychiatry F ward, Manouba, Tunisia
2. La Rabta hospital, Biochemistry department, Tunis, Tunisia

AUTHORS
1. Noomen Bouaziz1, Mr, MD, 2. Imene Ayedi3, Mrs, 3. Oussama Sidhom1, Mr, MD, oussama_sidhom@yahoo.fr
4. Amen Kallel2, Mrs, 5. Rym Rafrafi1, Mrs, MD, 6. Wehid Melki1, Mr, MD, 7. Ridha Jemaa2, Mr, MD
8. Moncef Fekih2, Mr, MD, 9. Naziha Kaabachi2, Mrs, Md, 10. Zouhair El Hechimi1, Mr, MD

Aims: Several recent studies suggested an association between hyperhomocysteinemia (HHC) and schizophrenia. The aims of this study were to:
1) Determine the prevalence of HHC and its main determinants in patients with schizophrenia; 2) Look for correlations between homocysteinemia (Hcy) and the clinical features of schizophrenia.

Methods: We included 33 male patients with schizophrenia, drug naive or drug free for the previous 3 months period, and 35 healthy male subjects as controls. Patients and controls were closely matched according to age and smoking habits. Plasma Hcy, vitamin B12 and folate levels determination, 5,10-methylenetetrahydrofolate reductase (MthFr) gene polymorphism analysis as well as clinical assessment using PANSS, SANS and SAPS, were made before antipsychotic administration.

Results: Prevalence of HHC was higher in patients [33.0% versus 11.4%; OR (95% CI), 3.88 (1.12-13.84); p=0.02]. Plasma vitamin B12 was significantly lower in patients. There was no significant difference of genotypic distribution and allelic frequency of the C677T MTHFR between groups. Hcy was significantly associated with some negative symptoms of schizophrenia, particularly « anhedonia-asociality » and« avolition-apathy » in SANS items.

Conclusion: This study showed an association between HHC and schizophrenia, especially with the negative symptoms of the disease. HHC seems to be linked to vitamin B12 deficiency, likely caused by a lack in dietary animal proteins. Determination of Hcy may be useful in patients with schizophrenia, all the more HHC correction is sensible to a simple medication.

9. Hernan Silva1, Dr., MD, hsilva@med.uchile.cl

Objective: to investigate the relationship between 5-HTTLPR polymorphism and personality traits in Chilean patients with borderline personality disorders. Methods: we studied 52 subjects (37 woman and 15 man) who met the DSM-IV diagnostic criteria for borderline personality disorder according to the International Personality Disorders Examination, without axis I diagnoses and drug-free at the moment of evaluation. Personality traits were assessed with the Spanish version of Eysenck Personality Questionnaire Revised (EPQ-R), 5-HTTLPR polymorphism, and 5HT1B, 5HT1A, 5HT2C receptors polymorphism were genotyped by PCR from peripheral blood.

Results: S-allele carriers (LS and SS genotype) showed higher scores in Neuroticism dimensions (P<0.01) than L- allele genotype patients. The differences were independent from gender and age. In the total sample, women were significantly more neurotic than men (P<0.01), but this difference appears only in the S-carriers patients. Meanwhile the LL genotype patients scores lower in Neuroticism than S-carriers and without differences between men and women. No significant association was observed between 5-HTTLPR polymorphism and other EPQ-R personality dimensions. No significant association was observed between personality dimensions and the other studied polymorphism.

Conclusion: S-allele carriers have higher scores in Neuroticism dimensions in the Chilean patients with borderline personality disorder studied. (Proyecto FONDECYT Ns 1071045)

1. Maja M Simonovic¹, Dr, MD, simonovicmaja@gmail.com
2. Grozdanko B Grbesa¹, Dr, PhD, grbesa@eunet.yu
3. Tatjana M Milenkovic¹, Mrs, minat@eunet.yu
4. Misa M Radisavljevic², Dr, MD, misara@ni.acc.yu

Aim. The aim of the paper is to determine characteristics of the clinical presentation of comorbid posttraumatic stress disorder and depression.

Method. The investigation included 60 patients assessed by means of the following instruments: Structured Clinical Interview for DSM-IV Axis I Disorders, Clinicians-Administered PTSD Scale, Montgomery-Asberg Depression Rating Scale and 17-items Hamilton Rating Scale for Depression. The data were analysed using the method of descriptive statistics. Differences between groups were evaluated using T-test.

Results. The results indicated that comorbidity of PTSD and depression is associated with higher intensity of intrusive symptoms cluster, especially with flashbacks and intrusive thoughts distinctive to either PTSD or to depression, with broader spectrum of emotional and mood experiences and with more patients' suffering.

Conclusion. Distinctive patterns of cognitive and emotional responses indicate the presence of PTSD and of depression. This analysis enabled better understanding of symptoms presented by the patient, choice of optimal treatment strategies and shed some light onto possible mechanisms of the human reactivity to extreme traumatic experiences.

4. Albert HC Wong²

Schizophrenia affects about 1.0% of the population worldwide, with devastating consequences for both patients and their families and is the seventh most costly medical illness. Linkage and association studies have now implicated several loci in the genome that likely harbor genes conferring risk for schizophrenia. NALCN (sodium leak channel, non-selective) is a gene located on chromosome 13q in a suggested linkage region for schizophrenia. Mouse NALCN mediates some background sodium leak in hippocampal neurons and plays a role in neuronal excitability. Abnormalities in hippocampal activity and neuronal excitability have been implicated in schizophrenia. In this study, we examined association with schizophrenia using family-based analysis. Twenty six NALCN polymorphisms were analyzed and allelic; genotypic and haplotypic frequencies were compared across 85 small nuclear families. We did not find any significantly altered transmission. Our results suggest that the NALCN may not affect susceptibility to schizophrenia.

Several psychiatry illnesses, such as schizophrenia and bipolar disorder, are associated to dopamine-mediated neurotransmission imbalances. It was shown that two proteins involved in dopamine signaling are altered in prefrontal cortex (PFC) of both schizophrenia and bipolar disorder subjects. DARPP-32 is downregulated and NCS-1 is upregulated in PFC of both disorder subjects. DARPP-32 is a key downstream effector of intracellular signaling pathway and NCS-1 is a neuronal calcium sensor that can inhibit dopamine receptor D2 internalization. It is well known that dopamine D2 receptor is the main target of antipsychotics. Therefore, our purpose was to study if chronic treatments with typical or atypical antipsychotics induce alterations in DARPP-32 and NCS-1 expression in vivo and in vitro. For in vivo experiments we used rats that were treated for 28 days with Clozapine, Haloperidol, Olanzapine and Aripiprazole. We observed expression in five brain regions: prefrontal cortex, hippocampus, striatum, cortex and cerebellum. For in vitro experiments we used P12 cells wt and stably overexpressing NCS-1 (Clone) that were treated for 7 and 14 days with Haloperidol, Clozapine and Risperidone. We used western blot and we did not find any changes in DARPP-32 and NCS-1 protein expression in any rats' brain regions and P12 cells investigated. Our findings allow the suggestion that both downregulation of DARPP-32 and upregulation of NCS-1 described in the PFC of schizophrenia and bipolar disorder patients might be related with the psychopathology of the disease and not with treatment with antipsychotic drugs.

Aims: comparison of influence of childhood trauma on HPA axis function examined by the use of dexamethasone supression test (DST) in depression, anxiety disorders and in healthy population.

Method: 72 patients were examined: 32 with depression (ICD-10 F32,F33), 22 with anxiety disorders (ICD-10 F41) and 15 healthy persons. The mean age of the patients was 38.5 years (SD-11.8). There were 37 women and 35 men. The level of cortisol before and after administering of 1 mg dexamethasone as per DST test at 8:00 a.m. and 4 p.m. was measured.

The following tests were conducted:
1. Early Trauma Inventory-ETI.
2. Social Readjustment Scale.
3. Hospital Anxiety-Depression Scale.
4. Sense of Coherence-SOC.

Results: There were differences for morning cortisol levels before DST (the highest in anxiety disorders) and in ETI (in depression and anxiety disorders the severity of trauma was significantly higher than in healthy population). The sense of coherence was the highest in healthy population. Emotional and sexual abuse in particular was modifying intrinsic naturalistic morning cortisol secretion in depression and afternoon and morning levels after dexamethasone administration in anxiety disorders. There was positive correlation between supression in DST and higher incidence of sexual abuse in healthy population.

Conclusions: The data confirm existence of disturbances of HPA axis function in depression, anxiety disorders as opposed to the healthy group and their correlation with childhood trauma.

AIMS: To examine associations between combat-related posttraumatic stress disorder (PTSD) and postwar psychosocial adaptation and physical health in Serbian veterans from the ex-Yugoslavia Civil War.

METHODS: Two hundred and twenty war veterans from several veteran organizations in three major Serbian cities, who voluntarily accept to join the survey, completed several questionnaires. Standardized self-administered screening instruments were used to assess symptoms of posttraumatic stress disorder (IES-R), psychological distress (SCL-90-R), and psychosocial postwar adjustment. Cut-off score of 2.0 on IES-R, was used to split the sample in two groups: PTSD (n=91) and non-PTSD (n=129).

RESULTS: Veterans with PTSD compared to veterans without PTSD had significantly more psychological, marital and professional problems. They had also more physical complaints and medical diagnoses and had more missed workdays. They were in increased risk for the alcohol, nicotine and other substance dependence.

CONCLUSIONS: These findings support the hypothesis that veterans with PTSD have increased risk to develop psychological, psychosocial and somatic dysfunction than veterans without PTSD, and may have important implications for future directions in social and health policy concerning this population.

8. Georgios Kaprinis1

Objective: Stroop test is considered as a reliable and sensitive tool for the assessment of executive functions. The aim of the study is to standardize Normative Data of the Stroop test in Greek Population.

Method: This is an analytic, experimental, cross sectional, stratified study. The population of the study is consisted of 274 adults from the general population. The study was stratified by age in years, level of education and sex. There were six age groups (18-29 years, 30-39, 40-49, 50-59, 60-69 and 70+), in three education level groups valued in years (1-9 years, 10-12, 13+). The dependent variables were three (1. time in seconds to complete reading each of the three cards, 2. the number of corrected mistakes, 3. the number of the uncorrected mistakes) for every one of the three cards of the Stroop test.

RESULTS: A table is created which is composed of the normative data of the Stroop test according to age group and level of education. In every entry of the dependent variable there are two values, the mean and the standard deviation, for each group.

Discussion: Normative data of the Stroop test is recommended for its use in the Greek population. The clinical utility of these Normative Data is to provide reference for the neuropsychological assessment of the Greek patients. Moreover these Normative Data of the Stroop test could be a useful tool for the Greek medical clinicians and researchers.

This paper analyses the condition of a 46 yrs male patient suffering from paranoid schizophrenia. He was treated with a combination of antipsychotic drug in doses that lead to manifest extrapyramidal symptoms.

Objective: The main goal is to show improvement in patient's functioning, especially the cognitive dysfunction after the adjustment of therapy (reducing and optimizing the combined antipsychotic therapy).

Methods: The methods we employed were: interview Wechsler-Bellevue (WB form II) test battery for IQ, MMPI inventory on personality. We have repeated the tests after six months, using the same battery of psychological instruments.

Results: The comparison of primary and repeated investigation shows: improvement in cognitive functioning, especially the attention and concentration and reducing the psychological and social imbalance. The patient improves his body position and articulation of the speech. After the six months treatment on outpatient's bases, the patient improved his family and social functioning.

Conclusion: The quality and design of psychopharmacological therapy of patients with schizophrenia is close related with their cognitive and general functioning.

THE SOCIO-ECONOMIC FACTORS AND THE DYNAMIC OF ADMISSIONS IN THE PSYCHIATRIC HOSPITAL

INSTITUTIONS
1. Special Psychiatric Hospital Gornja Toponica, Nis, Serbia and Montenegro
2. Clinic for Mental Health Protection, Nis, Serbia and Montenegro

AUTHORS
1. Zoran Stevanovic1, Dr, sphtop@bankerinter.net
2. Vojin Popovic1, Prim,dr
3. Zagorka Stevanovic2, Dr
4. Milan Stanojkovic1, Dr

Aims: During the last fifteen years large socio-economic changes occurred in Serbia. Since the year 1994. to 1998. Socialistic Federative Republic of Yugoslavia violently fell apart, with civil wars raging across the former republics, and devastation of the Serbian economy. In the year 1999. Serbia itself was struck by the war and massive destruction. Since the end of 2000. a slow restoration of Serbia begins, but with many negative consequences of transition.

Method: Some characteristics of admissions in Special Psychiatric Hospital in Gornja Toponica in the period since 1994. to 2007 were retrospectively viewed.

Results: In this period 19529 patients were admitted. The number of admissions was reduced during 1998. and especially during 1999. but was increasing constantly since then, and in 2007 number of admissions was twice as high as in 1999. In this period there were significant oscillations in the procedural frequency of some diagnostical categories, and most of all disorders caused by the misusage of psychoactive substances. In the beginning of research period percentage of the patients diseased with diagnoses F10-F19 was continuously reducing to the minimal 20.78% in 1999, and then rises until it's doubled in 2007 - 42.81%. At the same time percentage of patients diagnosed with F20-F29 was reducing from 51.84% to 31.22% in 2007.

Conclusion: Significant socio-economical changes like war, disbandment of country and transition have very large influence on the dynamics of admissions in to the psychiatric hospital, and these changes are mostly noticed at patients that have substance-related disorders.

Study of a neurotransmitter substrate of spatial navigation is one of the most investigated topics in cognitive neurosciences. Active allothetic place avoidance (AAPA) task is a spatial behavioral paradigm allowing simultaneous assessment of changes in spatial behavior and locomotion of experimental animals. In the present study, we investigated the involvement of alpha1-adrenergic and dopamine D2 receptors in the locomotor activity and the spatial efficiency in the AAPA task. We administered specific receptor antagonists prazosin (1 and 2 mg/kg) and sulpiride (10 and 30 mg/kg) either separately, or co-applied them together. Results show that co-application of both drugs affects locomotion and behavior of rats at the doses, which cause minor or no impairments when injected independently. Such a potentiation of effect suggests that both types of receptors act synergistically to regulate the locomotion in the AAPA task. However future experiments are required to elucidate whether the behavioral deficit occurs as a result of decreased locomotion, or evolves as a stand-alone phenomenon. The presented experiments also support the usefulness of the AAPA task in the study of animal cognition.

Supported by grants GACR 309/07/0341, IGA MZ CR NR/9178-3 and by MŠMT CR centers 1M0517 and LC554.

STUDY OF THE SPATIAL AVOIDANCE BEHAVIOR IN RODENTS

INSTITUTIONS
1. Institute of Physiology, Academy of Sciences, Dpt. of Neurophysiology of Memory and Computational Neuroscience, Prague, Czech Republic
2. Prague Psychiatric Center, Prague, Czech Republic

AUTHORS
1. Ales Stuchlik1, RNDr., PhD., stuchlik@biomed.cas.cz
2. Vera Bubenikova-Valesova1,2, Dr., PhD.
3. Karel Vales1, RNDr., PhD., vales@biomed.cas.cz

Spatial behavior of rodents is considered as a model of higher cognitive functions in humans. Ten years ago, a novel spatial paradigm, active allothetic place avoidance (AAPA), was designed in our laboratory. In this task, animals avoid an unmarked shock sector defined in a coordinate frame of experimental room while moving over a rotating arena. It was established that besides navigation with respect to a hidden place, the task requires cognitive coordination, usually explained as an ability to separate spatial stimuli from the environment into coherent representation of an arena and a room, and to select the room frame as the only relevant one for efficient navigation. Effects of specific receptor ligands on the behavior of animals in AAPA task were studied. It was found that changes in spatial performance are often accompanied by alterations in overall locomotor activity. In this regard, the task has an advantage of simultaneous assessment of both place navigation and locomotor behavior. The analysis of locomotion was found to be important for exclusion of a more general impairment of animals after an experimental manipulation. The results suggest that at least in some cases, the changed locomotion and decreased spatial efficiency occur without a mutual causal relationship. The presentation will summarize the existing evidence about neurochemical modulation of behavior in this spatial task.

Supported by grants GACR 309/07/0341 and IGA MZ CR NR/9178 and by MŠMT center 1M0517.

6. Arpine L. Kirakosyan¹, Miss, MD, PhD

Objective: To find out the main causes for the first application to the psychiatrist among patients of a center of mental health.

Method: It was designed clinical-epidemiological questionnaire to collect the data. There was a methodological limitation in this study: our study group included patients presenting to a specialized clinic and therefore the findings are not exactly generalizable to all psychiatric populations.

Results: The sample was 148 patients, 49 (33.1%) of which couldn’t remember and mention the nature of complains, which are the cause for the first application to the psychiatrist. The rest 99 patients (66.9%) mentioned 391 foremost symptoms, which brought them to the psychiatrist. Of this 391 symptoms most frequent were different sleep disorders (15.1%, n=59), anxiety (12.8%, n=50), somatic-vegetal complains (12.3%, n=48), and depressive symptoms (11.5%, n=45). Phobias and painful sensations mentioned 38 patients (9.7%). Further were following cerebro-asthenic complaints (8.7%, n=34), suspiciousness (8.4%, n=33), somatic complains (6.65%, n=26). In spite of the generally accepted opinion, about the third part of the patients himself had suggested to apply to the psychiatrist (35.8%), in main cases (41.2%) the patients had applied for the help of psychiatrist by the insistence or request of relatives, and in 22.3% of cases they had referred by specialists of general practice (internists, neurologists and others).

Conclusions: The first signs of the manifestation of mental disorders predetermine further level and character of the psychiatric disorder. Every fifth patient was revealed in the general-somatic settings of health care and referred to the specialized clinic.

It has been demonstrated that the interaction between serotonin transporter (5HTT) and norepinephrine transporter (NET) functions affects each transporter function and behavior in studies using knockout mice model. In the present study, we examined the effect of the interaction between the 5HTT and NET gene promoter polymorphisms on personality traits in 575 healthy Japanese subjects. The 5HTT (long/short, L/S) and NET (-3081 A/T) genotypes were identified by PCR methods, and personality traits were assessed by the Temperament and Character Inventory (TCI). Neither of the two polymorphisms affected any TCI dimension, but the interaction between them had significant effects on harm avoidance and novelty seeking in females. Subsequent analyses showed that the females with the combination of the SS genotype reducing 5HTT function and the TT genotype reducing NET function had significantly higher harm avoidance and lower novelty seeking. The present study suggests that the interaction between the 5HTT and NET polymorphisms influences harm avoidance and novelty seeking in females.

Background: Parenting requires evolutionarily conserved sets of thoughts and behaviors, somewhat like obsessions and compulsions. At two time-points in the early postpartum, we assessed the thoughts, behaviors and associated brain activity of new mothers and fathers using interviews and functional magnetic resonance imaging (fMRI).

Methods: We scanned and interviewed 1st-time parents at 2-4 weeks and 3-4 months postpartum. At each time point, fMRI scans assessed brain activity while listening to own vs. other-baby-cries. Within days of interviews, they completed interviews to assess patterns of anxiety-related parenting thoughts and behaviors. Results: In 1st time mothers, studied at 2-4 weeks postpartum, own-baby-cries activated amygdala, hippocampus and parahippocampal tissue important for attention, determination of salience, and anxiety. Activations occurred in basal ganglia regions related to repetitive thoughts, reward and goal-directed behaviors. The activity of several regions was significantly correlated with postpartum preoccupations, including the orbitofrontal cortex, basal ganglia, amygdala, substantia nigra, insula, and cingulate and fusiform. Two regions contained correlations across populations of mothers and fathers across two time-points: the orbitofrontal cortex and the insula. Among first time mothers, the change in anxiety correlated with the change in activation in these areas.

Conclusions: These data indicate that new parents respond to own-baby-cries in key anxiety, arousal, and emotion centers, and that some of those activations correlate with postpartum preoccupations at repeated time-points. Some of these responses are also common to fathers, and vary over the first few months postpartum in concert with the reduction in parental anxiety and the maturation of parent-infant attachment.

ONE-YEAR FOLLOW-UP STUDY OF BURDEN OF CARE AND COPING STRATEGIES IN FAMILIES OF PATIENTS WITH SCHIZOPHRENIA IN JAPAN

INSTITUTIONS
1. Nagasaki University Graduate School of Biomedical Sciences, Department of Health Sciences, Nagasaki, Japan
2. Jichi Medical University, School of Nursing, Tochigi, Japan

AUTHORS
1. Goro Tanaka\textsuperscript{1}, Mr., PhD, goro@net.nagasaki-u.ac.jp
2. Setsuko Hanzawa\textsuperscript{2}, Ms, PhD, hanzawa@jichi.ac.jp
3. Hiroyuki Inadomi\textsuperscript{1}, Mr, PhD, inadomi@nagasaki-u.ac.jp
4. Yasuyuki Ohta\textsuperscript{1}, Dr, MD, PhD, y-ota@nagasaki-u.ac.jp

Aims: Few follow-up studies have investigated the burden of care in families of patients with mental disorders in Japan. A 1-year follow-up study was conducted to ascertain burden of care and coping strategies in families of patients with schizophrenia.

Methods: Subjects were 54 consenting members of the Nagasaki Federation of Families of People with Mental Disorders living with patients who were diagnosed with schizophrenia and being treated on an outpatient basis. Mean age of schizophrenia patients was 37.9±8.4 years, with 76% men and 24% women. Mean age of subjects was 65.3±9.0 years, with 22% fathers, 72% mothers and 6% others. Burden of care was assessed using the 8-item short version of the Japanese version of the Zarit Caregiver Burden Interview (J-ZBI-8). Coping strategies were assessed using the Family Coping Questionnaire (FCQ).

Results: Social functioning was stable in patients. While the burden of care was reduced, no significant differences were identified. Of the FCQ items, information-seeking behaviors and behaviors to facilitate social involvement of patients significantly decreased. During the study period, reduced burden of care correlated significantly with the following FCQ items: less information-seeking behaviors; and increased social interests. Reduced coerced behaviors correlated with higher attendance at monthly federation meetings.

Conclusions: These results suggest that reduced burden of care correlates with improved coping strategies. As subjects were members of a self-help group, the results may not apply universally, but are useful for designing more effective programs for supporting families of patients with mental disorders.

DYNAMIC OF SICKNESS WITH PERSON IN PRE-SENILE AND SENILE AGE DURING 10 YEARS IN ARMENIA

INSTITUTIONS
1. Yerevan State Medical University by M. Heratsy, Department of psychiatry, Yerevan, Armenia

AUTHORS
1. Karine Karlen Tataryan1, Dr, MD, tataryank@yahoo.com

Actuality: Researching of gerontological contingent's mental disorders in Armenia is carried out firstly. Knowledge in real prevalence of mental disease in pre-senile and senile age can provide realization of a number organizing and treating prophylactic tasks. But as the patients' turning for mental aid is low, that's why it led to low revealing of mental pathology.

Aim of the research is studding the dynamic of sickness with persons in pre-senile and senile age during 10 years (1995-2004) and also inspected contingent's some social-demographic factors.

Material of the research is documentation of the pointed contingent, who turned for professional help to 'Nork' republic center of mental health during 1995-2004 years.

Results of research: 224 patients' histories are studded. Analysis of data let to reveal the following. Women are predominated among the persons joined hospital (91 men, 133 women). The ration between man and woman is 1:1.5. The most part of the patients are in age of 60-70 (80,3%), persons of 71 year and older is 19,7%, older 80 years is 1 person (0,4%). The dynamic of 10 years showed, that the number of hospitalised patients is increased from 1995, increased twice in 1998-1999. Such dynamic is observed till 2004. Pension is main living source for most part of patients (84,8%).

Conclusions: Studding of senile and pre-senile ages' mental disorders' prevalence and epidemiological regularity in RA is let to deve-lop measures for forming geronto-psychiatric aid in Armenia.

Objective: The purpose of this study was to investigate the effectiveness of the Brazilian version of the Liebowitz Social Anxiety Scale in identifying social anxiety disorder among patients with alcohol dependence, since the anxiety symptoms may be a trigger for relapse (1). Furthermore, many persons with alcohol use disorder also meet criteria for social phobia (2, 3).

Method: In a sample of 300 patients with alcohol dependence hospitalized in 3 mental clinics in Southern Brazil, 24.6% of them were social phobics. The SCID-I/P was used to check for the diagnosis of social anxiety disorder. In an attempt to obtain a global assessment of the discriminating power of the scale considering all possible cutoffs, a receiver operating characteristic (ROC) analysis was done.

Results: The adapted version of the scale was at its best performance in terms of identifying social phobia when using a cut-off score of 44 (sensibility=89.2; specificity=91.2). The discriminating power of the scale as measured by ROC analysis resulted in an area under curve of 0.964.

Conclusion: The scale can be useful in identifying social phobia among Brazilian alcohol dependents.

4. Anders Thelin3, Dr, PhD, athelin@wgab.se

Objective: To analyze the effects of rural residence and farming with respect to psychiatric mortality and morbidity in terms of hospital admittance. Our hypothesis was that the Swedish rural living and farming have a salutogenic impact on the psychiatric mortality/morbidity.

Methods: A cohort of 1,220 farmers, 1,130 non-farming rural referents, and 1,087 urban referents from nine Swedish municipalities were identified in 1989. This study population was followed over 12 years and data on mortality and hospital admissions were obtained from national registers. Mortality hazard ratios (HR) with 95% confidence intervals (95% CI) were computed with the proportional hazard regression technique (Cox’s regression), and Fisher’s exact test was used for small numbers. For morbidity odds ratios (OR) with 95% CI were computed.

Results: No statistically significant differences in psychiatric mortality were found. Non-farming rural men had almost half the risk of total as well as alcohol related psychiatric morbidity compared with the urban referents. The risk of non-alcohol related psychiatric morbidity was even lower. The farmers’ psychiatric morbidity was one fourth compared to urban referents, with the largest difference in alcohol related morbidity. Furthermore, the farmers’ depression, anxiety and dementia morbidity was significantly low. There were major differences in the risk of hospital admittance for self-destructive actions with only one and two cases among non-farming rural men and farmers respectively, compared to fourteen cases among the urban referents.

Conclusion: Swedish rural living and farming in particular, implies low risk of mental health disorders.

AIMS/OBJECTIVES. The major aim of the study was to explore the relationships between burnout and personality characteristics in medical personnel.

METHODS. Measures administered included Russian version of Maslach Burnout Inventory (MBI) and Russian version of Spielberger’s State-Trait Personality Inventory (STPI/RU, adopted by Oleg Radyuk in 2001-2007). 40 physicians and nurses were examined.

RESULTS. Mean values of the measures were the next, state curiosity: 22.10 ± 0.97, state anger: 12.05 ± 0.50, state anxiety: 17.05 ± 0.70, state depression: 13.33 ± 0.65, trait curiosity: 29.50 ± 0.96, trait anger: 17.40 ± 0.53, trait anxiety: 18.28 ± 0.58, trait depression: 18.90 ± 0.67, emotional exhaustion: 23.28 ± 1.15, depersonalization: 9.43 ± 0.79, personal accomplishment: 27.13 ± 1.35. By Spearman’s correlation analysis, the following results were found: emotional exhaustion was related to state anxiety (0.514, p < 0.01), trait anxiety (0.474, p < 0.01), state depression (0.518, p < 0.01) and trait depression (0.527, p < 0.01); depersonalization was related to state anxiety (0.368, p < 0.05), trait anxiety (0.454, p < 0.01), state depression (0.436, p < 0.01) and trait depression (0.461, p < 0.01); personal accomplishment was related to state (0.497, p < 0.01) and trait curiosity (0.518, p < 0.01); personal accomplishment was negatively correlated with the state anxiety (-0.556, p < 0.01), state depression (-0.400, p < 0.05) and trait depression (-0.589, p < 0.01).

CONCLUSION. There are significant relationships between MBI scales and STPI personality characteristics (anxiety, curiosity, anger, and depression) in medical personnel.

Aims/objectives: This study aims at assessing the psychodynamics behind the family relationships of psychiatric patients, the necessity and utility of approaching mental health disorders using family therapy. Method: 34 families (120 members) have been invited for study participation. The criteria used were: one family member suffering from mild or moderate depression according to DSM-IV and ICD-10. Prior to psychotherapy sessions we assessed depression severity using The Hamilton Rating Scale for Depression (HRSRD), the Global Assessment of Functioning Scale (GAFS) for the given patient along with the family indicator of functioning—The Family Functioning Scale (FFS). There were twelve psychotherapy sessions lasting between 60 to 90 minutes scheduled as follows: once every week during the first two months, once every two weeks for the next two months and then monthly. After the last therapeutic session the patient and his/her family were reassessed using the same indicators: HRSRD, GAFS, FFS. The control group consisted of 123 mental disorder-free families that we analysed using the FFS.

Conclusions: 1. There was a major decrease in intensity and relapsing for cognitive and autonomic depression. 2. There was a global improvement as well as an improvement in various compartments of functioning. 3. There was an obvious progress pertaining to the overall family functioning in multiple areas, whereas regarding relationships there was a switch from symmetrical to complementary and from distant to close.

Clinical studies have proved that schizophrenia is accompanied by hypoalgesia, but only a few of them examined this phenomenon in detail. We induced schizophrenia-related alterations by subchronic ketamine treatment and social isolation in rats to determine their long-lasting effects on nociception.

Materials and Methods
Wistar rats after weaning (n=40) were either housed individually or grouped for 32 days, and were treated daily with either an increasing dose of ketamine or saline. Tail-flick latencies were determined before starting the treatment and after the last drug administration, at 46, 48 °C (C-fiber activation) and 52 °C (affects mainly Aα-fibers). After testing rats were rehoused. At 5th week acoustic prepulse inhibition (PPI) was tested to observe the reflex modification affected by social isolation and/or ketamine treatment.

Results
As regards tail-flick latencies at 46 and 48 °C, juvenile isolation but not ketamine treatment resulted in a significantly enhanced pain threshold, while the changes at 52 °C were not significant. Social isolation impaired the PPI. Ketamine treatment by itself did not reduce the PPI, but caused a further impairment.

Conclusion
In summary, social isolation exerts significant effect on acute heat pain sensitivity in young animals, disturbing primarily C-fiber linked pain pathways, while subchronic ketamine administration did not influence it. However, PPI revealed a more pronounced deficit after the combination of these two treatments. Thus, our study suggests a selective disturbance in the parallel sensory pathways under these experimental conditions. This work was supported by grants of RET-08/04 OMFB-0066/2005 and OTKA, K60278.

Objective: To report an experience of adaptation and acculturation as it has occurred for a qualitative researcher in a specialized healthcare service addressed to people with Chemical Dependency at the Psychoactive Substances Outpatient Service, State University of Campinas, São Paulo, Brazil.

Method: record of fieldnotes based on the following sources: researcher’s work as a professional participating of a follow-up including clinical discussion relative to the patients; through activities of coordination of motivation groups; and through participation of theoretical workshops with the staff.

Results: Concept of adaptation includes an adjustment to routines of the setting which will serve as investigation field, as well knowing the staff and the patients. Acculturation is the process of adopting cultural values of certain community. It occurs as an assimilation of the peoples’ though way and habits. It is established in order to obtain information about eventual difficulties into the approach, as well as to have a deep analysis on how those people handles the question that will be the study object. This phase can last weeks or a few months. The empirical data used to help to delimit the authors’ subject research.

Conclusion: adaptation and acculturation, as strategy to validation of collecting data in field research, are crucial to perform an adequate relationship with the subjects.

The estimated genetic risk for schizophrenia was calculated on 40-50%. Some researchers believed that inheritance of the susceptibility to schizophrenia was caused by epistatic activity of multiple genes. The aim of our study was to find:

1. Genetic markers influencing susceptibility of paranoid schizophrenia. The polymorphisms of COMT, MAO A and GRIK3 genes were studied.
2. Relationships between different gene variants and both: the treatment efficacy measured by the PANSS.

The group of 75 patients with paranoid schizophrenia consisted of 39 men and 36 women. There were no significant differences between groups according to gender, age of onset and duration of illness. Patients were treated randomly with perazine, olanzapine or ziprasidone. The control group consist of 406 healthy volunteers ethnically, gender and age matched.

Results: No differences were found in the allelic distribution in COMT and GRIK3 genes polymorphisms between the whole schizophrenics and the control group. An analysis of allele distribution in VNTR polymorphism of the MAO-A gene showed that an allele with three tandem repeats within the promoter region of this gene was significantly more frequent in women with paranoid schizophrenia compared with the healthy population. No association was found between any particular genotype of the studied polymorphisms and the effect of antipsychotic treatment.

* The study was conducted under the Pfizer Independent Research Grant no. 2005-0039.

Major depression is often associated with dysregulation of the hypothalamic–pituitary–adrenal (HPA) axis. Most studies on HPA axis dysregulation in major depression have focused on cortisol. By comparison, dehydroepiandrosterone (DHEA) has been less extensively studied in depressed patients. The physiological role of DHEA is not completely understood. DHEA is a substrate for androstenedione and testosterone synthesis, and may have a role as an adrenal androgen. However, there is evidence to suggest that it may extend effects in the central nervous system. Importantly, DHEA opposes the action of glucocorticoids. One of the simplest and most frequently used methods which assess the HPA axis is the measurement of peripheral levels of adrenal steroids. This can reliably be done in plasma or urine, however an increasing number of studies have highlighted the advantages of saliva in this respect. This study examined whether salivary cortisol and DHEA can use as biological markers in depressed patients. As a result, in patients compared with controls, salivary DHEA was significantly elevated, in conjunction with normal cortisol levels. This result suggests that DHEA may be a more sensitive indicator of depression than cortisol in depressed patients.

Background The concept of vascular depression postulates that pathological (ischemic) changes in certain brain areas could raise the risk of depression in late life. Stroke-related depression is regarded as a type of vascular depression. Despite numerous studies on post-stroke depression (PSD), the role of cerebral atrophy and white matter lesion in the pathogenesis of PSD remain uncertain. The aim of this study was to evaluate the MRI correlates of PSD in Chinese patients with first or recurrent stroke.

Method A total of 293 Chinese patients consecutively admitted with acute ischemic stroke to the acute stroke unit of a university-affiliated regional hospital in Hong Kong were recruited. MRI scans were performed within the first 7 weeks following admission. Three months after the index stroke, a psychiatrist interviewed all participants and diagnosed PSD according to DSM-IV criteria.

Results Thirty-four (11.6%) was diagnosed with PSD 3 months after their index stroke. In the univariate analysis, severe frontal lobe atrophy (15.2% vs 5.1%; PSD vs non-PSD subjects) and severe subcortical and deep white matter lesions (14.7% vs 3.1%; PSD vs non-PSD subjects) were significantly associated with PSD (p<0.05). These MRI findings remained significant after adjusting for age, and gender in logistic regression analysis.

Conclusion Frontal lobe atrophy and white matter lesions were independent predictors of PSD.

Background To our knowledge there has been no publication on frontal lobe functions in post-stroke emotional incontinence (PSEI). The aim of this case-control study was to assess whether patients with PSEI have impaired frontal lobe functions.

Method Five-hundred and nine Chinese patients with acute ischaemic stroke consecutively admitted to the acute stroke unit of a university-affiliated regional hospital in Hong Kong were recruited. According to Kim’s criteria (Kim et al., 2000), 39 (7.7%) subjects had poststroke emotional incontinence (PSEI) 3 months after the index stroke. Thirty-nine stroke patients without PSEI served as the control group. The frontal lobe functions were assessed by the Stroop Test, Modified Card Sorting Test (MSCT), Modified Verbal Fluency Test (VFt), Go-no-Go test, and the Frontal Assessment Battery (FAB), 3 months after the index stroke. The severity of depressive symptoms was measured with the Geriatric Depression Scale (GDS).

Results The words reaction time in the Stroop test (35.42±14.22s vs 28.25±10.73s), the number of omission (6.14±3.81 vs 4.31±3.00) and commission (9.03±6.32 vs 5.31±3.34) errors in the Go-No-Go test as well as the FAB total scores (13.44±1.77 vs 14.38±1.55) significantly differed between the PSEI and control groups (p<0.05). Having adjusted for the Geriatric Depression Scale (GDS) scores, the differences in the words reaction time in Stroop test and number of commission error in Go-No-Go test remained significant.

Conclusion Impairment of frontal lobe function exists in PSEI and appears to be independent of concurrent poststroke depression.

AIM & OBJECTIVE: The clinical presentation responses to the pharmacological treatment of Adult patients with early and late onset OCD were compared in this study.

METHODS: A total of fifty OP patients diagnosed according to DSM IV TR Criteria were included in the study. After initial clinical evaluation with Structured Clinical Interview for DSM IV/Clinical version (SCID-I/CV) and Yale Brown Obsessive Compulsive scale (Y-BOCS) all patients were treated with fluvoxamine, sertraline and clomipramine for 10 weeks. Treatment response was defined as a 35% reduction in the Y-BOCS total scores from baseline in a 10 week follow up period.

RESULTS: Forty three patients completed the study. The early onset group had higher frequencies of exactness/symmetry obsessions and arranging/ordering compulsions and the late onset group had higher mean age assessment. Nine patients with early onset and Eighteen patients with late onset responded to pharmacological treatment. The difference between response rates was not statistically significant.

CONCLUSIONS: Our study suggests that there are some phenomenological difference between patients with early onset OCD and late onset OCD, these patients have similar responses to pharmacotherapy. Our study suggests that there are some phenomenological difference between patients with early onset OCD and late onset OCD, these patients have similar responses to pharmacotherapy.

NEGATION TO EXECUTE CONDITIONED REFLEXES: ORIGIN OF THE MENTAL ILLNESS.

INSTITUTIONS
1. CENTRO DE INVESTIGACIÓN, DIFUSION Y PROMOCION DE LA LIBERTAD INTERIOR (CIPLI), RESEARCH, TRUJILLO, Peru

AUTHORS
1. Juan Miguel Vargas Ponciano, Dr., PhD, cipli@algoesoi.com

Objective: Correct handling of the extinguishment of conditioned reflexes orientates toward the restitution of the lucidity and incorporation at the homeostasis again.

Method: Planned introspection and meticulous evolved record of all internal conflicts triggered after the tireless search of the I, during 30 years.

Results: Association and reinforcement of the punishment with the freedom and disobedience, for allowing the appearance of the I, considered like a transgression, and the recompense, with the obedience, allowing the arising of a false personality or I', which value : The Social Conditioning. Exact equivalence between the punishment gave to a child and the obsessive-compulsive disorder. Persistent disobedience of a child, for pretending Being Himself, opposite a infuriate father for losing his authority, precise reproduction of all the nosologic psychiatry’s classification.

Conclusion: The First step toward the real being search points out the beginning of the Mental Illness. The conditioned reflexes extinguishment -with full consciousness- unchaining unrecognizable internal contradictions, is onset of the RESURRECTION OF THE I, but its incorrect handling is cause of ‘Dead in Life’ or Mental Illness: Structure and dynamic repeat invariably in all the clinical cases. Religion and Schizophrenia are improved, stylized and sophisticated polar extremes of the social conditioning.

CHANGING FAMILY STRUCTURE AND MENTAL HEALTH SERVICES IN THE UNITED STATES

INSTITUTIONS
1. Indiana University School of Medicine, Indianapolis, Indiana, United States

AUTHORS
1. Vijoy K Varma, Professor, MD, FRCPsych, vijoyv@comcast.net

There has been a sea change in the United States, for example, in the last 30-40 years in family integrity and support. The development not always occurring in a linear fashion, many developing countries, just being ushered into the industrial revolution are, at the same time experiencing many stresses of post-industrialization. The classical dyadic marital relationship for life has largely disappeared. In olden days, there used to a husband and a wife, wedded for most of adult life, and the resultant children, all full siblings. It has given way to what has been described as serial monogamy. In addition, there has been a large-scale increase in living together without marriage. Children can be full siblings, half-siblings and step-siblings. It is often difficult to keep track of them, even for the persons concerned. It creates major strains for children. “Your children and my children are beating our children.” At the same time, the U.S. suffers from a continuing problem in providing for health care services, often hotly debated. About 15% of the total population does not have any health insurance and lacks the resources to meet health care costs. It is much higher for minorities and the poor. More importantly, as much as about 30% of the mentally ill lack it. As opposed to many other countries, the U.S. does not have a state-supported universal health care coverage. A major problem in outpatient services in mental health centres is to arrange medication for the patients.

5. Diana Ojog

Objective: Cognitive interpretations of stressors instigate processes as coping and cognitive reappraisals that directly enable or disable an individual to deal with stress [1]. Our study’s main objective was to evaluate the impact of coping strategies over the evolution of acute stress disorder.

Methods: A group of 23 patients, 16 female and 7 male, mean age 31.2, diagnosed with acute stress disorder (DSM IV TR), were admitted in our hospital and assessed using Hamilton Scale for Anxiety (HAMA) and a cognitive-oriented interview [2] in order to establish the severity of anxiety and the coping mechanisms for each individual.

Results: Patients with acute stress disorder presented active coping (n=4), seeking emotional social support (n=3), suppression of competing activities (n=2), focus on emotions (n=3), denial (n=3), mental disengagement (n=5), behavioral disengagement (n=2), alcohol use (n=1). HAM-A scores were higher in patients with less efficient coping strategies (any form of disengagement, alcohol use, denial, focus on emotions) than in persons using more efficient strategies (+13.5 points, p<0.01).

Conclusion: Patients with acute stress disorder and efficient coping strategies have a less significant level of anxiety and therefore a better prognosis than individuals with low effective coping skills.

LOW INCOME AND POVERTY POSSIBLE RISK FACTORS FOR SCHIZOPHRENIA

INSTITUTIONS
1. Psychiatry hospital-Skopje, Skopje, The former Yugoslav Republic of Macedonia

AUTHORS
1. Viktor M. Isjanovski
2. Igor M. Isjanovski

Schizophrenia is one of the most complexes of all mental health disorders. There is no known single cause responsible for schizophrenia. However, it is likely that many factors play a role in the development of this mental health condition. Sch is considered to be multifactorially inherited. Multifactorial inheritance means that “many factors” are involved. Low income and poverty increases the risk and play role in ethyopatogenesis of Sch. Our aim of this study is to reject or accept hypothesis that social stress of poverty, low education status, and finance disability as a result of unemployment are possible risk factors for appearance of Sch. Material for these investigation are two clinical groups, who are in psychiatric hospital- 60 with diagnosis Sch and 60 without. 50% from the investigate groups are unemployment and 35% were employment before (85% unemployment, now), these percent in the control group are 61%.(p=0.004). There are association between unemployment and registration of Sch (x^2 - Yates corrected = 6.22; p=0.02). According OR, unemployment make six time grater chance for developing Sch (OR=6.201,142 = 22.76; p=0.00), have not financial resources make six time grater chance for developing Sch (OR=6.562,742 = 11,18; p=0.0008280), poverty make tree time grater chance for developing Sch (OR=3.721,58)

Objective: to investigate the relationship between 5-HTTLPR polymorphism and personality traits in Chilean patients with borderline personality disorders. Methods: we studied 52 subjects (37 woman and 15 man) who met the DSM-IV diagnostic criteria for borderline personality disorder according to the International Personality Disorders Examination, without axis I diagnoses and drug-free at the moment of evaluation. Personality traits were assessed with the Spanish version of Eysenck Personality Questionnaire Revised (EPQ-R). 5-HTTLPR polymorphism, and TPH1, 5HT1B, 5HT2C receptors polymorphism were genotyped by PCR from peripheral blood. Results: S-allele carriers (LS and SS genotype) showed higher scores in neuroticism dimensions (p<0.01) than LL allele genotype patients. The differences were independent from gender and age. In the total sample, women were significantly more neurotic than men (p<0.01), but this difference appears only in the S-carriers patients. Meanwhile the LL genotype patients scores lower in Neuroticism than S-carriers and without differences between men and women. No significant association was observed between 5-HTTLPR polymorphism and other EPQ-R personality dimensions. No significant association was observed between personality dimensions and the other studied polymorphism. Conclusion: S-allele carriers have higher scores in Neuroticism dimensions in the Chilean patients with borderline personality disorder studied. (Project FONDECYT Nº 1071045)

2. Alla Kholmogorova, Dr., PhD, psylab2006@yandex.ru

Objectives: The study is aimed at the system research of familial factors of depressive and anxiety disorders: familial stressful life events, domestic violence, parental perfectionism, criticism and hostility. Methods: 187 patients (97 with depression and 90 with anxiety disorders) and 60 healthy people were administrated originally developed Family stress scale and Parental Family Emotional Communications’ Style Inventory. 55 parents of patients and 30 parents of healthy people were administrated original perfectionism and hostility scales. Results: Major stressful life events like severe illnesses of closest relatives, incidents with closest relatives, fights and abuses were more often in families of patients. Patients suffering from depressive and anxiety disorders differ on these scores from control group at statistically significant level. When compared with healthy control, patients more often witnessed severe illnesses or deaths of closest relatives. Chronic familial stress in form of parental criticism, alcoholism, fights and abuses were identified in both groups of patients. Parents of both groups demonstrated high level of perfectionism and hostility compared with parents of healthy people. Conclusions: In the parental family history of people with depressive and anxiety disorders chronic familial stress and major stressful life events occurred, which are similar in both group of patients. Parents of patients with depressive and anxiety disorders demonstrated high level of perfectionism and hostility.

Abstract Body:
In process of deinstitutionalisation of psychiatry in Europe more and more psychotic patients will live at their homes with their families. Some members of family get now new role in family life. They become caregivers. The role of caregivers is stressful and engaged with high risk of depression, psychosomatic disorders, insomnia, feelings of anger and rage, fall of immunity and many somatic disorders. Then caregiver becomes invisible patient. He is in shadow of psychotic family member. Family goes through period of accommodation and gives care and help to your ill member. This is a modification of family life, hierarchy, relations between family members and homeostasis. The negative feedback mechanism such as appearance of psychosomatic disorders at one member of family is trial to establish homeostasis. The role of therapist is to give help to caregiver so they can recognize, interpret and understand symptoms.

A COMPARATIVE STUDY ON PSYCHOSOCIAL STRESS BETWEEN JAPANESE AND KOSOVAR COLLEGE STUDENTS

INSTITUTIONS
1. Kyushu University, Institute of Health Science, Fukuoka, Japan

AUTHORS
1. Kazuhiko Yamamoto¹, Dr., MD, PhD, yamamoto@design.kyushu-u.ac.jp
2. Yoko Sakamoto¹
3. Gazmend Kacaniku¹, Dr., MD, PhD

Objectives:
The aim of this study was to examine whether there was any difference in psychosocial stress between Japanese and Kosovar college students.

Methods:
Psychosocial stress and stress tolerance capacity were measured using the IMPS and IMST, respectively (1). 360 Japanese college students (212 men and 148 women) and 104 Kosovar college students (62 men and 42 women) responded. The mean ages of Japanese and Kosovar college students were 19.0 ± 1.0 and 22.2 ± 2.0 years, respectively.

Results:
Japanese college students reported more subjective stress than Kosovar college students, and IMPS-measured stress score was higher in women than in men among Japanese college students. In contrast, Kosovar college students had lower stress tolerance capacity than Japanese college students. While IMPS-measured stress score was higher in women than in men among Japanese college students, there was no difference in the score between men and women among Kosovar college students. The factor analysis of IMPS scores using maximum likelihood factoring and Promax rotation indicated that the structure of psychosocial stress among Japanese college students, which consists of 10 factors: “despair and anxiety,” “somatization,” “hostility and resentment,” “sleep disturbances,” “ticking,” “strain,” “inattentiveness,” “isolation,” “impatience” and “physical hypersensitivity” was different from that among Kosovar college students, which consists of 14 factors: “somatization,” “disgust and isolation,” “anxiety and avoidance,” “sleep disturbances and agitation,” “hostility,” “despair,” “resentment,” “uneasiness,” “hypersensitivity,” “strain,” “irritation,” “helplessness,” “discord” and “dysautonomia.”

Conclusion:
It was concluded that Japanese college students suffered more psychosocial stress than Kosovar college students and that there was a substantial structural difference in psychosocial stress between these two groups.

2. Faye A. Gary², Dr., PhD, fgary@case.edu

Aim: In the United States, during the first decade of the 21st century, it is estimated that about 21 million women will become menopausal. African American women experience numerous health deficits that negatively influence their health status.

Method: This study (n=206) reports on the relationship between employment, menopausal knowledge, socioeconomic status, education, support systems, depressive scores, and health status among a group of rural African American women who were recruited from their communities. It used path analyses to determine the relationship among the selected variables and the African American women’s health status. Specifically, the paper will feature the best-fitting model for the advancement of the theory that is described by Marmot and colleagues who proposed the social determinants of health theory. The statistical analysis consists of descriptive statistics, correlation analysis, multiple regressions, and path analysis.

Results: The results indicate that the social determinants of health model can be used to explain the variables that affect the women’s health. In addition, their over exposure to poverty and stress make them vulnerable to mortality and morbidity that are expressed through a variety of diseases.

Conclusion: African American women are at risk for numerous health conditions that are related to the social determinants of health. The model that Marmot proposed is relevant for understanding and intervening with African American women.

3. Su Ting Hsu¹, Dr., MD, PhD
4. Jung Kwang Wen², Dr., MD

Objective: This study explored the effectiveness of multiple-family psychoeducation intervention for mentally illness families’ burden, stigma and satisfaction.

Methods: 31 families of patient with major mental illness attended this family intervention over 3 months (10 sessions). At the beginning and immediately after 3 months, measurements included family’s needs on psychoeducation (base line), care-giver burden scale, stigma of mental illness and global satisfaction (feedback).

Results: totally 31 families (75% attendance rate) participated in this family intervention. Despite there was no significance difference in care-giver burden before and after the intervention, the scores of all items was lower. A significant reduction in the perceived stigma of mental illness after intervention. Feedback questionnaires with ratings of the usefulness of each session on a 5-point scale. Overall, the responses were positive. Feedback from families showed that the atmosphere of the group was warm, moving, supportive and secure. The families learnt more knowledge of mental illness and skill of caring as well as understood their relatives with mental illness. In addition, this intervention facilitated collaborative partnership relationship between families and professionals who were their key practitioners, and increase trust in mental health care.

Conclusions: Multiple-family psychoeducation program is an effective intervention in helping family of mental illness in promoting mental health care in a psychiatric setting. The findings suggest continued implementation and development of family intervention in Taiwan is promising and encouraging despite there are on-going challenges to be overcome.

A CASE OF SHY-DRAGER SYNDROME WITH DEPRESSION:
ANTI-DEPRESSIVE AND ADVERSE EFFECTS OF M-ECT

INSTITUTIONS
1. Jichi Medical University, Psychiatry, Tochigi, Japan

AUTHORS
1. Takaaki Abe1, Dr., abetak@jichi.ac.jp

Although the effectiveness of modified electroconvulsive therapy (m-ECT) in cases of idiopathic Parkinsonism has been confirmed in the literature, few studies have investigated the effectiveness of m-ECT among patients with multi-systemic neurologic degeneration, including Shy-Drager syndrome. We report a case of Shy-Drager syndrome, with depression, successfully treated with m-ECT. The patient was a retired 65-year-old man who suffered from fatigue, apetite loss, insomnia and psychomotor inhibition. He was diagnosed with major depression and prescribed antidepressants. Because depressive symptoms were not improved with pharmacotherapy, he was hospitalized for m-ECT. After each trial of m-ECT (3 in total), however, he experienced dizziness and falls to the floor caused by orthostatic hypotension. Additional findings, including mild cerebellar ataxia (mild cerebellar atrophy on MRI) and neurogenic bladder, were identified by a neurologist, and he was subsequently diagnosed with Shy-Drager syndrome. Although the m-ECT was stopped earlier than scheduled because of these adverse effects, his depressive state improved remarkably. Although we should be cautious about the use of m-ECT in patients with Shy-Drager syndrome, it appears to effectively treat depression caused by this syndrome.

OBJECTIVE: Traditionally the effects of psychotherapy have been measured before the beginning and after the end of therapy. In the context of the theoretical construct of synergetic it becomes evident that psychotherapy is a non-linear process, characterized by the occurrence of phases of instability that are followed by cascades of cognitive-affective phase-transitions (Haken & Schiepek 2006). To identify the phases of critical instability a new method has been implemented in the case of a patient with OCD

METHODS: Daily evaluations online were made by a patient with obsessive compulsive disorder, subtype washing/contamination fear during the course of a behavioral psychotherapy program. The patient filled out a 46 item questionnaire encompassing 7 factors daily online. No medication was administered.

RESULTS: Two phase transitions became apparent - the first one shortly after admission, the second after a conflict with other patients. Overall, the patient's general level of functioning improved. In a short follow-up investigation he was found working and able to live on his own.

CONCLUSION: Real time monitoring during the process of psychotherapy has the advantage of being able to grasp phases of critical instability followed by transitions into new patterns of clinical status display during the process itself. Psychotherapy is a non-linear process during which the patterns of self-organization change by undergoing transitions which are evoked by phases of critical instability (Haken & Schiepek 2006). Real-time monitoring enables us to improve our understanding of how psychotherapy works.

SOMATOFORM PAIN DISORDER WITH COMORBID INSOMNIA: IMPROVEMENT OF PAIN AND SLEEP PARAMETERS AFTER 6-WEEK TRAZODONE CR THERAPY

INSTITUTIONS
1. Medical University Hospital of Vienna, Psychiatry, Vienna, Austria
2. Medical University Hospital of Vienna, Psychiatry, Vienna, Austria

AUTHORS
1. Wolfgang Praise, Dr.
2. Martin Aigner, Prof. Dr., martin.aigner@meduniwien.ac.at

Purpose of the study:
The aim of the present study was to investigate the acute and chronic effects of trazodone on objective and subjective sleep parameters and pain in somatoform pain disorder (SPD) patients with nonorganic insomnia.

Methods:
Fifteen patients (7 females), aged 50.1 ± 11 years, participated in the single-blind, placebo-controlled, cross-over study on the acute effect of 100mg trazodone, followed by a six-week open titration period to the optimum dose (155.6 ± 39.1 mg). Polysomnographic evaluation was performed by the Somnolyzer 24x7 classification program in 5 nights. The patients were compared with 15 age- and sex-matched healthy subjects derived from the Siesta database.

Results:
Acute administration of trazodone reduced the number of nocturnal awakenings and increased deep sleep stages. These effects on objective sleep parameters were also observed after six-week therapy. Clinical evaluation showed an improvement in the Pittsburgh Sleep Quality Index, Zung Anxiety Scale and State/Trait Anxiety Inventory and VAS score. After 6 weeks of daily use of trazodone CR, 4 out of 6 pain parameters demonstrated a significant improvement.

Conclusions:
Insomnia in SPD was mitigated by acute trazodone therapy. After six weeks the improvement of objective and subjective sleep quality was associated with a significant improvement of pain and its psychosocial consequences.

6. Evrim Erten, DR, MD
7. Fusun Aran, Dr, MD

Objective: Despite bipolar patients spend up to one third of their lives in depression; most of acute treatment guidelines for bipolar disorder focused mainly on manic phase of illness. There are only a few efficient treatment choices for bipolar depression. Many studies showed that antidepressant agents have significant efficacy in the treatment of bipolar depression. One of the most controversial points in bipolar depression is the treatment of patients with antidepressant drugs although they induce switching to mania and cycle acceleration. As there is not enough data concerning this subject it is aimed to elucidate this crucial argument in this study.

Method: Clinician behaviour and antidepressant treatment preferences during 288 depressive episodes were evaluated in Rasit Tahsin Mood Disorders Outpatient Clinic. Time to remission as well as duration until next episode and subsequent episode type of patients were compared between patients receiving antidepressants or other drugs as of treatment choice.

Results: We found that clinicians preferred to add new agents in most of the episodes (%34.4) and were in need of trying more than two other choices (29.6%). Clinicians preferred antidepressant treatment in about two thirds of the episodes (37.8%), but no significant differences were found between the two groups by means of remission and relapse.

Conclusions: Antidepressant treatment during depressive episodes did not make any difference in remission and relapse time. Data seem to support the result of Systematic Treatment Enhancement Program for Bipolar Disorders Study (NIMH STEP-BD).

Objectives: There is increasing evidence that cognitive impairments in bipolar patients may be associated with the vulnerability of the disorder as impairments have been evidenced both in euthymic bipolar patients and in unaffected relatives. Previous studies have reported cognitive impairments also in schizophrenia families. The aim of the present study was to examine the cognitive functioning in bipolar I disorder patients and their unaffected relatives in a group of families with bipolar disorder and in families mixed with bipolar and schizophrenia spectrum disorders.

Methods: A neuropsychological test battery was administered to 20 bipolar I disorder patients and 37 unaffected relatives from bipolar families, 19 bipolar I disorder patients and 28 unaffected relatives from mixed families and 55 controls, all representing population-based samples.

Results: In both groups, patients and relatives were impaired in psychomotor processing speed. Patients from bipolar families were worse than controls in nearly all measures of verbal learning and memory. Patients from mixed families were impaired only in delayed verbal recall. Both patients groups were impaired in executive functioning, although patients from mixed families were most impaired. Relatives in both groups were slightly impaired in executive functioning.

Conclusion: Our findings suggest that impaired psychomotor processing speed and executive function may represent vulnerability markers of bipolar disorder irrespective of psychopathology in the family. Increased abnormalities in executive functioning may be associated with increased liability to schizophrenia spectrum disorders. In addition, increased abnormalities in verbal memory may be associated more with pure bipolar disorder.

The aim of the study is to investigate vegetative reactivity at the different stages of depressive episode.

Methods: Clinico-psychopathological method, clinico-anamnestic method, the Zung self-rating depression scale, the method of the heart rate variability analysis for assessment of vegetative regulation. The study is conducted from 2000 to 2007. In the first part of the study the assessment of vegetative regulation at the initial stage of depressive episode is provided (82 patients even 72 healthy persons). In the second part the vegetative regulation is studied at the stages of stabilization and reduction of depressive episode (76 patients even 66 healthy persons).

The results of investigation are shown reduction in the total heart rate variability, increase in tension level of regulatory systems at the initial stage of depression. The activity balance of the sympathetic, parasympathetic and suprasegmental mechanisms of autonomic nervous system remains. At the stage of depression stabilization the disruption of different components of autonomic nervous system balance occurs. The prevalence of the activity of suprasegmental ergotropic systems and the functional decrease of sympathetic mechanisms activity are observed. At the stage of the depression reduction the decrease of the activity of suprasegmental ergotropic systems with the hyper-activation of peripheral sympathoadrenal mechanisms are revealed.

Conclusion: Obtained data could be considered in chose and efficiency rating of therapy at the different stages of depression.

AUTHORS
1. Maria João Avelino, Dr., MD, mariajoaoavelino@gmail.com
2. Liliana Paixão, Dr., MD
3. Mário Borrego, Dr., MD
4. Ana Caixeiro, Dr., MD

AIMS: Obsessive-Compulsive symptoms (OCS) have been presented in a great proportion of patients diagnosed with Schizophrenic Psychosis. The studies that tried to analyse the demographic and clinical differences of those Schizophrenic patients with OCS or OCD comorbid vary widely in terms of prevalence. In a psychopathological approach, OCS in Schizophrenia can: hardly be distinguished from psychotic symptoms; appear at the prodromic phase; occur simply as a comorbidity or be induced by antipsychotic therapy. The aim of this work consisted on a revision on scientific literature about the presence of OCS in schizophrenia, more precisely about the proposed mechanisms to their arising/exacerbation by atypical antipsychotics (AAP).

METHODS: The authors present a case report of a 29 year old man, diagnosed with Paranoid Schizophrenia, that developed OCS after therapy changing to oral quetiapine and zuclopentixol depot and, make a bibliographic investigation (in PUBMED) about those assumptions.

RESULTS: There have been described case reports of development/exacerbation of OCS in Schizophrenic patients with AAP, especially with clozapine, olanzapine and risperidone. There are only two cases associated to quetiapine therapy [1]

CONCLUSION: There is not an exact explanation for the pathogenic mechanisms involved in the development of OCS after the administration of AAP and, like in the current case report, many factors must be taken into account when trying to make that relationship.

HYponatremia ASSOCIATED WITH SELECTIVE SEROTONIN REUPTAKE INHIBITOR IN PATIENTS WITH MAJOR DEPRESSIVE DISORDER: A PRELIMINARY REPORT

INSTITUTIONS
1. Department of Psychiatry, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of Korea

AUTHORS

2. Young-Eun Jung
3. Ho-Jun Seo
4. Jeong-Ho Chae
5. Tae-Youn Jun

Hyponatremia (serum sodium arbitrarily defined as less than 135 mmol/L) is an increasingly recognized adverse effect of selective serotonin reuptake inhibitors (SSRI). Its precise prevalence and incidence in patients with major depressive disorder (MDD) are hard to determine because of confounding factors including other prescribed medications and medical conditions. The aim of this study is to estimate the prevalence of hyponatremia associated with the use of SSRI in MDD patients compared to that in MDD patients with the use of other antidepressant drugs. The inpatients with MDD, who were treated with one adequate trials of antidepressants at least for 4 weeks were selected for a retrospective study. Demographic variables and serum sodium concentration were compared between the use of SSRI and the use of other antidepressant drugs. One hundred fourteen patients were included. Four patients (6.9%) on SSRI (N=58), one patient (1.8%) on non-SSRI (N=56) had hyponatremia during study period. All patients developed hyponatremia were female, elderly, 23 and below of body mass index. There was no statistically significant difference on the serum sodium concentration changes at week 2 and 4 from baseline between two groups. Larger, prospective studies would enable more accurate collection of data including follow-up over time and differentiation of the relative risk of hyponatremia with individual SSRIs.

Aims: Treatment-resistant depression (TRD) is a long-term, disabling illness. It is not clear, if the combination or augmentation of antidepressants are more effective than antidepressant (AD) monotherapy in the treatment of TRD (1, 2).

Methods: In this retrospective chart review, we compared the efficacy of combined therapy (combination AD or augmentation) versus switching to monotherapy (both at least 4 weeks) in inpatients, who had not responded at least to one previous antidepressant trial. Depressive symptoms were assessed using Montgomery-Åsberg Depression Rating Scale (MADRS) and response was defined as a reduction of MADRS ≥50%. Results: We analyzed 49 depressed inpatients (24 in the combined condition and 25 in the monotherapy). Both groups are equal in baseline characteristics (number of previous treatment, severity of depression etc.) and in the length of index treatment. The combined treatment was superior to the monotherapy switch in the MADRS score reduction (16 vs. 10, respectively, p < 0.01) and the proportion of patients in response (67% vs. 36%, p=0.05).

Conclusion: The results of these analyses suggest that combined treatment may be more effective than a monotherapy in patients with TRD.

**NEUROPSYCHIATRY OF OBSESSIVE COMPULSIVE DISORDER IN INDIVIDUALS WITH INTELLECTUAL DISABILITIES**

**INSTITUTIONS**
1. University of North Carolina School of Medicine, Psychiatry, Chapel Hill, United States

**AUTHORS**
1. Larry Jarrett Barnhill Jr.\(^1\), Dr., Jarrett_Barnhill@med.unc.edu

AIMS/OBJECTIVES: The diagnosis of obsessive-compulsive disorder (OCD) among individuals with developmental disorders is complicated by symptom diversity inherent to both conditions. The aim of this presentation is to address problems in differential diagnosis created by this heterogeneity. We will discuss the process of differentiating OCD from other forms of repetitive behaviors.

METHODS: The author will utilize a systematic analysis of case-study materials to demonstrate the process of defining endophenotypes of repetitive behaviors.

RESULTS: OCD is a subset of a larger group of repetitive behaviors. Because of the dimensional nature of many OC symptoms, we need to pare down this symptomatic diversity in order to better define the syndrome of OCD. This process includes addressing the level and severity of pre-existing developmental disorder, gender, age of onset, pattern of neurophysiological responses and temperament, threat perception, threshold and habituation for arousal, impact of known brain disorders, genetic vulnerabilities and behavioral phenotypes, comorbid neuropsychiatric disorders such as autism or movement disorders, and previous responses to treatment.

CONCLUSIONS: OCD is best considered a spectrum disorder that lies along a continuum of conditions with distinct but overlapping neurobiological substrates. In order to cope with this heterogeneity, clinicians need to integrate presenting target behaviors with an extensive neurobiological and functional behavioral analysis as well as a thoughtful investigation of specific comorbid neuropsychiatric disorders. We can resolve some of this confusion by systematically analyzing the behavioral neurobiology of repetitive behaviors.

COLOR SENSITIVITY AND MOOD DISORDERS: BIOLOGY OR METAPHOR?

INSTITUTIONS
1. Towson University, Towson, United States
2. Emerald Health Center, Reisterstown, United States

AUTHORS
1. Christina Barrick¹, Dr., PhD. cbarrick@towson.edu
2. Dianne Taylor¹, Dr.
3. Elsa I. Correa², Dr.

Aims/Objectives: The purpose of this pilot study was to test three hypotheses concerning the relationship between mood disorders and color sensitivity. Methods: Using a cross-sectional survey design consisting of a sample of 120 inpatients and outpatients, color sensitivity was assessed by the patient’s response to a self-report depression scale item, “I notice that everything seems gray/cloudy/drab/ lacking color”. Results: Color sensitivity significantly correlated with depression in the total sample (p = 0.001). The other two hypotheses approached significance but were not supported. Discussion: These findings suggest there is evidence that color sensitivity is impaired during depression. Further research using a larger, more homogeneous sample and longitudinal design whereby measures of mood and color sensitivity are correlated before, during, and after treatment in depressed and manic patients would be justified. A study using ophthalmological instrumentation to measure color sensitivity would provide objective, ‘hard’ evidence of the association between color sensitivity and depression. Conclusion: Whether color perception is metaphorically reported by patients to describe their mood or a biological phenomenon remains to be validated. Findings seem to lend support to the conclusion that abnormalities in brain function alter retinal function.

5. Béchir Ben Hadj Ali⁵, Pr., MD

The incoming of major depression disorder (MDD) is the recurrence in 75% of cases. Objective: To determinate the predictive factors of MDD recurrence, the present study aimed to compare two groups of patients with recurrent MDD and with MDD, single episode. Methods: It's a comparative study held in the psychiatric female inpatient unit of Farhat hached university hospital of Sousse (Tunisia). All first time admissions, between January 1999 and December 2006, for MDD according to DSM-IV criteria, were retrospectively examined (N=277). Assessment of demographic, clinical and outcome features was based on patients’ medical charts. Statistical comparisons were performed between two groups of inpatients: Group 1 (G1): inpatients with recurrent MDD (n=149) Group 2 (G2): inpatients with MDD, single episode (n=128). Results: Inpatients from G1 were older (p=0.002) and had more family antecedents of mood disorder (p=0.046). They also had more severe episodes (p=0.01) and more endogenous characteristics (p=0.01). Age of onset, episode durations, personality disorders and axis I morbidity were similar between the two groups. Conclusion: Family history of mood disorders, endogenous characteristics and episode severity were correlated to depressive recurrence, in our inpatients. These factors should be taken into account to adapt psychiatric care in case of occurrence of first major depressive disorder.

DOES POLARITY DISTINGUISH MAJOR DEPRESSIVE DISORDER AND BIPOLAR II DISORDER?

INSTITUTIONS
1. Hecker Psychiatry Research Center at Forli, Italy, University of California at San Diego Collaborating Center, Psychiatry, Forli, Italy

AUTHORS
1. Franco Benazzi1, Professor, MD, PhD, FrancoBenazzi@FBenazzi.it

Recent epidemiological studies did not find a boundary between bipolar II disorder (BP-II) and major depressive disorder (MDD), as a subsyndromal hypomania (defined by at least 2 to 3 episodic symptoms) was more common than syndromal hypomania. Study aim was testing if polarity of episodes (history of hypomania) could categorically distinguish BP-II and MDD.

Methods: Consecutive sample of 274 remitted BP-II and 129 MDD outpatients interviewed about history of past episodes of hypomanic symptoms by Structured Clinical Interview for DSM-IV, in a private practice. Questioning about the most common symptoms, and the most common duration, of past hypomanic episode/s (lasting at least 2 days, including at least 2 hypomanic symptoms).

Results: As expected by definition, BP-II versus MDD had significantly more past, episodic, hypomanic symptoms. However, MDD had episodes of subsyndromal hypomanic symptoms (median symptom number = 3). Frequency of past episodes of at least 2 hypomanic symptoms in the entire sample, according to the number of symptoms per episode, was normally distributed (no bi-modality). A grading (linear correlation, r = 0.57, p = 0.000) of the number of episodic hypomanic symptoms was also found between BP-II and MDD.

Discussion: Study findings do not support current splitting of BP-II and MDD based on polarity of episodes. Complementing epidemiological findings, hypomania (at least as currently defined by DSM-IV) does not seem to be a distinct, categorical clinical entity. A continuum of past episodic hypomanic symptoms was found, sug-

2. Shahrokh Sardarpoor Gudarzi2, MD, sh_gud@yahoo.com
3. Sahar Tahbar Hosseinzadeh3
4. Nazanin Shayryari4, MD

Objective: This study is designed to examine the prevalence of mental disorders among medical inpatients, the detection of mental disorders by non-psychiatrist medical staff (including the nurses and other specialties) and the extent of referral for psychotherapeutic intervention in a general hospital in Tehran (Taleghani Hospital).

Method: In order to study the prevalence of mental disorders, GHQ (General Health Questionnaire-28) and MINI (Mini International Neuropsychiatric Interview) were administered to 124 patients (52.4% female and 47.6% male) in different medical wards. Physicians’ Diagnostic Questionnaire and Nurses’ Diagnostic Questionnaire were used to determine the detection of mental disorders by medical staff and the history of referrals for psychotherapeutic interventions was studied by using patient’s records.

Results: The current study revealed the high prevalence of mental disorders among medical inpatients specially females and patients at the age range of 20-40. The most prevalent disorders were mood disorders (44.4%), anxiety disorders (18.9%), substance-related disorders (4%) and psychosis (2.4%). 19.1% and 25.2% of the mentally-ill patients were detected correctly by physicians and nurses respectively. However, only 2.9% of these patients were referred to the psychiatrists for psychotherapy by medical staff.

Conclusions: A minor percentage of patients are detected correctly and referred for psychotherapeutic interventions by medical staff. It seems necessary to have training courses in psychiatry for the medical staff to help them detect and refer psychiatric patients immediately to advance the general health of the medical patients and to reduce the cost of the medical wards.

2. Sergio Baxter Andreoli 1, Dr, MD, PhD
3. Fábio Leite Gastal 2, Dr, MD, PhD

Objective: The main purpose of this study is to investigate the association of osteoporosis and depression in an elderly community population in Brazil.

Method: Cross-sectional population-based random sample of 7040 household residents aged 60 years and over, examined in a face-to-face interview. Self-rated presence of osteoporosis, sociodemographic variables, health behavior and self-rated health, ADL, and current depression (assessed through the Short Psychiatric Evaluation Schedule) were assessed through a structured interview. The main outcome measure of the investigation is the presence of osteoporosis. Logistic regression analysis was used to control for demographic, health and other mediating variables (health status, ADL). The sociodemographic variables were first added to the model, then other mediating variables (social support, health behavior, health status). Psychiatric morbidity was the last variable added to the model.

Results: The overall prevalence of osteoporosis morbidity was 15% (males 5.9%, females 19.8%). In controlled analyses, gender (females), low income, African-Brazilian, place of birth (urban), self-rated health (impaired), ADL impairments, were significantly associated with osteoporosis. When depression was added to the model it has an independent contribution for osteoporosis increasing the odds by 50%. The other covariates were not associated with osteoporosis morbidity.

Conclusion: The overall prevalence of osteoporosis was 15%. In controlled analyses, rates were higher in females, with low income, racial minority, with poorer health and functional status. Psychiatric morbidity makes a unique and independent contribution to osteoporosis.

RELATIONSHIPS BETWEEN PTSD, DEPRESSION AND QUALITY OF LIFE IN CROATIAN WAR VETERANS

INSTITUTIONS
1. University Hospital Centre Zagreb, Clinic for Psychological Medicine, Zagreb, Croatia
2. Croatian Studies, Zagreb, Croatia

AUTHORS
1. Marijana Bras 1, PhD, MD, mbras@kbc-zagreb.hr
2. Rudolf Gregurek 1, Prof., MD, gregurek@mef.hr
3. Maja Boban 2, Mrs, mbras@kbc-zagreb.hr
4. Barbara Kalenic 1, Mrs, bkalenic@kbc-zagreb.hr

Aims/Objectives: PTSD profoundly affects the psychological and physical health of veterans and their families. In some studies, nearly half of the veterans who had PTSD were also depressed. However, only few data exist reflecting the quality of life (QoL) in patients with chronic PTSD. In this study the authors analyzed the interrelationships between chronic PTSD, depression and QoL in Croatian war veterans.

Methods: The 184 veterans who were treated at the Clinic for Psychological Medicine during year 2007 were selected as the sample for this study. On the base of medical records, interviews and different self reported questionnaires (Mississippi Scale for combat-related PTSD, Beck Depression Inventory, WHOQOL-Bref, SCL-90) the authors analyzed the relationships between depression, somatization, QoL and chronic PTSD, as well as different therapeutic approaches that were used in the treatment of those patients.

Results: There was significant correlation between PTSD symptoms and intensity of negative emotions, fear of possible injuries and problems with concentration. We found negative correlation between intensity of PTSD symptoms, vitality, energy level and physical endurance. PTSD symptoms were associated with a poorer quality of life (physical and mental) and an increase in psychological distress. The patients with PTSD demonstrated a pronounced tendency for somatization and state anxiety.

Conclusion: The presence of PTSD symptoms predicted lower QoL and it is important for the treatment priorities and efforts. Relationship between chronic PTSD, depression and QoL requires a multidisciplinary approach to the assessment and treatment of patients with the emphasis on rational polypharmacy and psychotherapeutical interventions.

EVALUATION OF THE ANXIETY AND DEPRESSION SYMPTOMS IN PRE-SURGICAL CARDIAC PATIENTS

INSTITUTIONS
1. Santa Casa de São Paulo, Psychology Services, São Paulo, Brazil

AUTHORS
1. Wilze Laura Bruscato¹, Mrs., PhD, wlbruscato@uol.com.br
2. Juliana Haddad David¹, Mrs, PhD, chpsicol@santacasasp.org.br

Introduction: Heart surgery allows one to symbolically move around psychological aspects that are the individual’s essence, leading him/her towards a re-significance of life.

Aim: To evaluate the association between patients’ report about anxiety and depression in the pre-surgical period and the result of the Anxiety and Depression Scale (HAD).

Method: The patients’ report was obtained from a closed question about the pre-surgical moment, followed by the application of HAD.

Results: 37 pre-surgical cardiac patients were seen, 58% male, with age between 40 and 80 years, low level of instruction and low social-economical level. 70.3% presented symptoms in HAD: 35.2% anxiety, 16.2% depression, and 18.9% anxiety and depression. The remaining (29.7%) did not present any symptoms. According to the patients’ report, 56.8% mentioned one of these symptoms, anxiety being the most accounted for (46%) along with other feelings such as: anguish, insecurity and fear facing surgery; 10.8% reported anxiety and depression and 24.3% did not mention any symptoms.

Conclusion: Some patients did not mention any symptoms, revealing difficulty in admitting the moment of weakness facing surgery and being in contact with own feelings. The factors that may have interfered in the patients’ report are low level of instruction, lack of orientation regarding surgery, and difficulty in accepting the disease and considering oneself sick, which would be important, once that a certain level of anxiety is desirable, because it pushes the patient towards an action and to self-preparation for surgery.

3. Luzia Dantas Santos¹, MRS, chpsicol@santacasasp.org.br
4. Carmen Neves Benedetti¹, Mrs., PhD, chpsicol@santacasasp.org.br

Aim: to investigate the meaning that the patient submitted to orthognatic surgery gave to his/her experience with dental-facial deformity, surgery and transformation of appearance.

Method: qualitative study about the experience of 10 people with ages between 24 and 53 years, submitted to orthognatic surgery at least one year ago.

Results: the coexistence with dental-facial deformity was a difficult experience, but one with which the patients had gotten used to. The decision for surgery came from either the dentist’s recommendation or due to the presence of unbearable painful episodes. The extreme change in appearance, associated to the fear of not being recognized caused great anxiety in the immediate pre-surgery and post-surgery periods. The assimilation of the new image was a lengthy process, as well as the adjustment to new eating habits and palatability.

3. Tiago Reis Marques3, MD
4. Mário Rodrigues Simões1, PhD

Aims/Objectives: Cognitive dysfunction persists in the euthymic phase of bipolar disorder and may provide a marker of underlying neuropathology and disease vulnerability. Discrepancies have emerged with regard to what dysfunctions remain during remission periods. The aim of this study was to ascertain whether euthymic bipolar patients would show impairment in verbal learning and memory and in executive functions compared with healthy controls. Secondly, to establish if there was a relationship between clinical and functional data and neuropsychological performance.

Methods: Thirty euthymic bipolar patients were compared with thirty healthy controls through a battery of neuropsychological tests assessing estimated premorbid IQ, attention, verbal learning and memory, and frontal executive functioning. The effects of subsyndromal symptomatology was controlled. Functioning was assessed with WHODAS-II.

Results: Remitted bipolar patients were significantly more impaired than controls in several measures of memory and executive function, after controlling for the effect of subclinical symptomatology, age, sex and educational level. Verbal memory and executive functioning impairment was related to world human organization disability assessment schedule II (WHODAS-II) scores, as well as to variables of the course of the illness.

Conclusions: Results provide evidence of neuropsychological impairment in euthymic bipolar patients, after controlling for the effect of subsyndromal symptoms, suggesting verbal memory and executive dysfunctions. Euthymic bipolar disorder patients had greater impairment on neurocognitive measures associated with prefrontal and hippocampal function. Cognitive impairment seems to be related to a worse clinical course and poor functional outcome.

University students are mainly adolescent youths that have left home for the first time and are facing new responsibilities that make them vulnerable and susceptible to depression. Thus, the aim of this study was to identify symptoms of depression, or depressive states in health course undergraduate students. The investigation was an exploratory, descriptive, survey type study with a quantitative analysis of data, carried out in a private university in the State of São Paulo, Brazil. The sampling was non-probability, accidental, made up of 609 students between the ages of 17 and 73, of both sexes, enrolled in the nursing, pharmacy and physiotherapy undergraduate fulltime and night courses, that signed the consent form for inclusion in the study. The instrument for data collection was composed of identification, eleven questions and the DSMIV-TR symptoms for depression.

The results showed that 79% of the participants did not have depression before entering the university but 20.4% did develop depression during their academic life. The reasons indicated by the 210 students for their depression were insecurity about their professional future 52.7%, loneliness and homesickness 26.5%, low self-esteem because of academic difficulties 21.7% and an excess of activities 21.7%. The investigation also revealed that 30% of the students suffered from suicidal ideation occasionally, whereas 1.79% had these sentiments frequently or always. Other factors that made academic life difficult were financial worries, self-affirmation, sexual relationships, socio-cultural maturing process and other problems linked to adolescence. The participants with depression were referred to councilors or mental health professionals.

Introduction: The social rank theory of psychopathology in general suggests that with the evolution of social hierarchies various psychobiological mechanisms became in synch to the success or failure in conflict situations. Particularly, subordinates and those who have lost status are at greater risk of pathology than winners and those of higher status. This theory, conceptualize defeat (arrest flight) as of special importance to the study of depression. Also, defeat dimensions of life events and difficulties have demonstrated is role as precipitants of depression episodes. We demarcate the role of defeat within the social rank theory of depression.

Method: A self-report measure of defeat, defeat scale, (Gilbert, P. & Allan, S., 1998) were translated and validated in Portuguese samples of students and patients and used to predict the social rank theory of depression. Samples were assessed with defeat scale and other social rank measures (e.g. social comparison and submissive behaviour) and psychopathology scales (e.g. Beck Depressive Inventory and Depression Anxiety Stress Scale).

Results: The defeat scale were found to have good psychometric properties in Portuguese samples, and significantly correlated with depression. They were also strongly associated with other rank variables. Defeat maintained a strong association with depression even after controlling for other variables and added substantially to the explained variance of depression after controlling for the other social rank variables.

Conclusions: Defeat scale may be a useful tool in the study of depression and defeat, appears to be an important variable for the study of depression and may also help to expand innovative links between human and animal models of psychopathology.

Objective: This study was conducted to evaluate the relationship between symptomatic subtypes of panic disorder, after factor analysis, and specific fearful cognitions, measures of psychopathology as general distress, intensity of panic, agoraphobia, depression and suicidality.

Method: a total of 100 consecutives patients suffering from panic disorder and agoraphobia using the DSM-IV criteria, who contacted our outpatient clinic at the Hospital of Magalhães Lemos in Oporto, Portugal, were assessed using The Anxiety Disorders Interview Schedule-Revised, The Beck Depressive Inventory, The Fear Questionnaire, The Hopkins Symptom Checklist-90-Revised and the Agoraphobic Cognitions Questionnaire.

Results: sample characteristics, measures of psychopathology, frequency and intensity of the majority of the symptoms were similar to that one reported in other studies. A principal-component analysis of the symptoms of the DSM-IV criteria for panic attack revealed four factors that accounted for 60.2% of the variance. Only three factors were considered including the cardiorespiratory, vestibular and digestive. Each of these factors was correlated differently to some specific fear cognitions and measures of psychopathology.

Conclusion: Our findings support the symptom subtyping of panic disorder and confirm a relationship between fearful cognitions and symptoms of panic attacks according to the circular model of panic; while correlations between factors and different psychopathological measures can be established.

Key words: panic attacks; panic disorder; factor analysis; psychopathology

**Aims:** There is evidence for cognitive dysfunction in depression; however, psychiatric comorbidity is often inadequately controlled (1-2). The aims of the present study were to examine the role of psychiatric comorbidity on cognitive functioning among depressed young adults, and investigate which disorder characteristics are related to cognitive dysfunction.

**Methods:** Performance in verbal and visual short-term memory, verbal long-term memory and learning, attention, processing speed, and executive functioning was compared between a population-derived form the same population (n=70). Furthermore, performance was compared between the subgroups of pure (n=69) and comorbid (n=57) depression.

**Results:** Mildly compromised verbal learning was found among depressed young adults, but no other impairments were evident in any of the assessed cognitive functions. Subgroups of pure and comorbid depression did not differ in any of the cognitive measures. Received treatment associated with more impaired verbal memory and executive functioning, and younger age at first disorder onset with more impaired executive functioning.

**Conclusions:** The findings indicate that a lifetime history of unipolar depression among young adults with or without psychiatric comorbidity may be associated only with minimal cognitive deficits, even when some residual depressive symptoms are prevalent. However, depressed patients with cognitive deficits seem to seek help.

**Aims/Objectives:** To investigate the possible impact of the increased use of antidepressants on suicide rates in the Italian Region of Friuli-Venezia-Giulia.

**Method:** Individual data of antidepressants prescriptions in Friuli-Venezia-Giulia from 1997 to 2006 were obtained from the regional prescription database, and linked to individual data on suicide for the same period that were obtained from the regional health information system. Age and sex were considered in the analysis.

**Results:** The number of users of antidepressants increased steeply, especially among the elderly and among women (1-3). SSRIs accounted for 73 % of the individual users in 2006. The number of Defined Daily Doses (DDD) per patient, and DDOS per 1000 inhabitants per day also increased (4). In parallel, the suicide rate decreased, in men as well as in women, especially in the elderly (1-3).

**Conclusions:** Suicide rates in Friuli-Venezia-Giulia have declined in agreement with the hypothesis that the use of antidepressants may prevent suicide.

A STUDY OF ANXIETY IN A PREGNANT SOUTH AFRICAN POPULATION

INSTITUTIONS
1. Chris Hani Baragwanath Hospital, Obstetrics & Gynaecology, Johannesburg, South Africa
2. University of Belgrade, Psychiatry, Belgrade, Serbia and Montenegro

AUTHORS
1. Zeljka Clark¹, Dr, MD, zeljka.clark@gmail.com
2. Danjiela Tiosavljevic Maric², Dr, MD

The experience of birth for many parents is often perceived as one event with no comparison to any other with regard the level of associated anxiety. Pregnancy and care for the unborn child is accompanied by a complex emotional state of mind. New duties and responsibilities along with the anticipated joy will unavoidably be mixed with feelings of fear. Subjective benefit and fulfillment of becoming pregnant as well as instinctive care for an unborn child will very often be interlaced with feelings of anxiety for the remainder of pregnancy, the act of delivery and anticipation of possible change for one’s own life, health and perception of the parental role. To assess the level of anxiety in a specific population group, 200 pregnant women were assessed in the antenatal clinic of The Chris Hani Baragwanath Hospital, Johannesburg, South Africa. The Hamilton test for anxiety was used as a validated test for anxiety. Around 30% of the pregnant population is HIV positive and it was therefore very interesting to evaluate this as an independent marker for increased anxiety. This sample size is further stratified into groups looking at the number of pregnancies, a history of previous pregnancy outcome, age and social-economic status. The data is analysed and results presented. Further research in this area is proposed.

SELF APPRECIATION AND AFFECTIVE TEMPERAMENTS IN PSYCHIATRIC NURSES

INSTITUTIONS
1. Escola Superior de Saúde de Portalegre, Centro de Estudos de Saúde Mental, Portalegre, Portugal

AUTHORS
1. Raul C Cordeiro¹, Prof., PhD, raulcordeiro@sapo.pt

An analysis about the Self Appreciation and the Affective Temperament of Nurses in Psychiatric and Mental Health Services, have a crucial importance, because this fact will influence many phenomena’s in nursing practice, like the capacity of develop relationships and create resistance to physical and psychological illness. A total of n=47 nurses, of both sexes, with average age of 38.57 years, working in Mental Health and Psychiatry Departments, in three Portuguese Hospitals, were inquired through a Questionnaire of direct application. In the Questionnaire, were introduced measures like: TEMPS-A Scale (Akiskal, 1998), translated into Portuguese, by Figueira and Severino (1999) and Scale of Self Personal Appreciation (Ribeiro, 2006). The obtained results indicate that the population, have, majority, a Hyperthymic Temperament. It was verified that the women presents a higher Self Personal Appreciation and his Self Appreciation is statistically related to the Ciclothymic and Anxious temperaments. The results also show that exist an association between the marital status and the Irritable Temperament, and between the Time of Service and the Ciclothymic and Hyperthymic Temperaments. Affective temperament of nurses seems to be a good predictor of leadership capacity in violence situation at psychiatric services.

6. Victor Fossaluza¹, Mrs., Master in statistics, victor.ime@gmail.com
7. Euripedes Constantino Miguel¹, Mr., PhD, ecmiguel@usp.br

**Objective:** to evaluate the clinical efficacy of Group Cognitive Behaviour Therapy (GCBT) and Selective Serotonin Reuptake Inhibitors (SSRIs) for OCD patients, using broad inclusion criteria.

**Method:** Patients were randomized for GCBT and SSRI. Patients with current age between 18 and 65 years, with YBOCS score of at least 16 and psychiatric comorbidities were not excluded. Exclusion criteria were: OCD secondary to brain trauma, stroke or malformation; current abuse of alcohol or other psychoactive substance, current presence of psychotic symptoms, suicidal risk, psychiatric or clinical comorbidity that might get worse with the medications used in the trial. Initial and 12 weeks' evaluations included YBOCS score and CGI. The last evaluation was performed by a researcher blind to the treatment received.

**Results:** One hundred and fifty-five patients, who attended inclusion criteria, were randomized to GCBT or SSRI treatment: 68 in GCBT group and 87 in SSRI group. Drop-out rates were 32.18% in SSRI group, and 20.59% in GCBT. YBOCS reduction were 23.13% (SE=3.38) in SSRI group and 21.74% (SE=2.86) in GCBT (p=0.55).

**Conclusion:** Although the SSRI group presents higher percentages of respondents and Y-BOCS reduction than the GCBT group, no differences between groups were statistically significant at 0.05 level in this sample. Responses to treatment were both smaller than in literature probably because of the broader inclusion criteria, better reflecting OCD population that search for treatment.

2. Carl Leukefeld², Mr, PhD
3. Daniela Benzano¹, Mrs, MD
4. Fernanda Pasquolo Souza¹, Mrs, MSc
5. Aristides Volpato Cordioli¹, Mr, PhD

**Objective:** Obsessive-Compulsive Disorder (OCD) is characterized by repeated and persistent attempts to control thoughts and actions using rituals to prevent feared or personally distressing outcomes. Cognitive Behavioral Group Therapy (CBGT) focus on Exposure and Ritual Prevention (ERP) has been shown to be effective for OCD. This study targets patients who refuse ERP, drop out precipitously, or do not benefit from CBGT.

**Methods:** The present behavioral trial examines the impact of adding 2-individual sessions of Motivational Interviewing (MI) and Thought Mapping (TM) to a 12 week CBGT outpatient treatment. 48 adults with OCD were randomly assigned from January 2006 to December 2006 to one of two conditions: (1) CBGT plus Minimum intervention, or (2) CBGT plus MI and TM in a general hospital in the South of Brazil.

**Results:** Both treatments were effective although patients treated with MI+ TM plus CBGT obtained a mean Yale-Brown Obsessive Compulsive Scale (YBOCS) reduction of symptoms of 100% while those treated with Minimum Intervention plus CBGT obtained a 71% reduction (p=.004).

**Conclusions:** Cognitive-behavioral group therapy has shown to be effective in reducing OCD symptoms. However, the rate of symptom reduction and percentage of patients who obtained full remission were significantly higher in patients treated with CBGT plus MI+TM.

7. Sonia Borcato, Mrs
8. Juliana Bello Diniz, Mrs
9. Cristina Silva Belotto, Mrs, MD
10. Euripides Constantino Miguel, Dr, Phd

Objectives: Our aim is to compare the performance of treatment naive OCD patients and controls on measures of visual and verbal memory. Literature suggests that obsessive-compulsive disorder (OCD) patients show cognitive impairments which can persist after the remission of symptoms, mainly of executive functions.

Methods: 17 OCD patients (DSM-IV criteria), with no pharmacological or psychotherapeutic treatments, and 17 healthy controls were assessed with the Wechsler Abbreviated Scale of Intelligence (WASI), Brief Visual Memory Test (BVMT), Rey Complex Figure, California Verbal Learning Test (CVLT), and Logical Memory subtest (WMS-R). Groups were matched by gender, age, level of education, hand dominance, socioeconomic status. Mann Whitney statistical test was applied.

Results: OCD patients showed an impairment on verbal IQ (p=0.003), when compared to controls, mainly due to vocabulary subtest (p=0.004). There was no difference on Full IQ (p=0.051), Performance IQ (p=0.173), similarity subtest (p=0.614), BVMT, Rey Complex Figure (p=0.249) and Logical Memory subtest.

Conclusions: Our study suggests that treatment naive OCD patients show a worse performance on vocabulary subtest, impacting on verbal and performance IQ when compared to controls. These results raise the question of the validity of applying IQ as matching criteria, suggesting that differences on this measure can be related to the disease itself. We hypothesize that worse performance of expressive vocabulary can be related to executive dysfunctions. Further studies are necessary to clarify these findings.

THE USE OF NEW ANTICONVULSANTS FOR THE BIPOLAR DISORDERS TREATMENT

INSTITUTIONS
1. Medical Center Diour jemaa, psychiatry, Rabat, Morocco

AUTHORS
1. Mohamedi Darghal, Dr, MD, darghal2@gmail.com

Introduction: Bipolar disorder or manic-depressive psychosis is a serious chronic disease and frequent, as it affects about 5% of the population, regardless of culture or of the human race. The socioeconomic cost it engenders is considerable.

Methods: Bipolar disorders are defined by criteria set in the latest edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM IV). There are several types of bipolar disorder, that all involve episodes of depression and mania to a degree, bipolar disorder is a lifelong illness. There are currently several subtypes of bipolar disorder (bipolar disorder, type I), (bipolar disorder, type II), (bipolar disorder, type III). Different subtypes of the disease bipolar belong to what is now called bipolar spectrum. This distinction is important clinically, because it is necessary for the therapeutic choice.

Results: Newer anticonvulsant medications, including lamotrigine, gabapentin, and topiramate are being studied to determine how well they work in stabilizing mood cycle. Four major mechanisms of action underlying the pharmacological effects of anticonvulsants:

Conclusion: Several anticonvulsant of the last generation are currently being evaluated in the treatment of bipolar disorder. So far, the Lamotrigine is studied as a mood stabilizer and antidepressant. These new treatments may represent a promising alternative for patients resistant to the former mood stabilizer, such as lithium and valproic acid. However, many studies are still needed to determine their effectiveness and their indications.

QUETIAPINE XR: MAINTENANCE THERAPY FOR MAJOR DEPRESSIVE DISORDER

INSTITUTIONS
1. AstraZeneca, Wilmington, United States
2. University of British Columbia, Department of Psychiatry, Vancouver, Canada
3. Psychiatric Research Clinic of Kuopio, Kuopio, Finland
4. AstraZeneca, Wayne, United States

AUTHORS
1. Catherine Datto\(^1\), MD
2. Raymond W Lam\(^2\), MD
3. Ulla Lepola\(^3\), MD
4. Dennis Sweitzer\(^4\), PhD
5. Hans Eriksson\(^1\), MD
6. Martin Brecher\(^1\), MD, DMSc, MBA

Aims/Objectives: To evaluate the efficacy and tolerability of extended release quetiapine fumarate (quetiapine XR) as once-daily monotherapy for maintenance treatment in patients with major depressive disorder (MDD).

Methods: A time-to-event (maximum 52-weeks), double-blind, randomized-withdrawal, parallel-group, placebo-controlled study (D1448C00005) of quetiapine XR monotherapy following open-label stabilization (minimum 12 weeks). Patients initially received quetiapine XR: 4-8-week open-label treatment, 12-18-week stabilization. Primary objective was to evaluate the efficacy of quetiapine XR versus placebo in increasing time from randomization to any predefined depressed event. Secondary variables included: change from baseline in MADRS and CGI-S total scores for the randomized period. Adverse events (AEs) were recorded throughout the study.

Results: 787 patients were randomized to double-blind treatment: 391 quetiapine XR; 385 placebo. The risk of a depressed event was significantly reduced for quetiapine XR vs placebo (implying increased time to the event): HR=0.34 (95% CI 0.25, 0.48); p<0.0001. 55 (14.2%) quetiapine XR- and 132 (34.4%) placebo-treated patients experienced a depressed event. Quetiapine XR was significantly superior in maintaining level of symptoms as measured by average change from randomization in MADRS total scores (quetiapine XR 0.17, placebo 2.03, p<0.001) and CGI-S (quetiapine XR -0.03, placebo 0.23, p<0.001). Open label AEs were similar to previous experience with quetiapine XR; most common AEs (>10% in the placebo group) were headache and insomnia.

Conclusions: Quetiapine XR monotherapy significantly reduced risk of relapse of depression in patients with MDD and was generally well tolerated during maintenance treatment.

AN INTEGRATIVE CONCEPTUAL FRAMEWORK FOR ASSESSING AND TREATING SUICIDE ATTEMPT

INSTITUTIONS
1. Military Medical Academy, Clinic of psychiatry, Belgrade, Serbia and Montenegro

AUTHORS
1. Dedic J Gordana\(^1\), Dr, Prof MD PhD, sdedic@sezampro.yu

Introduction/Aim: Attempted suicide is a complex behavior that can be best thought of as a maladaptive response to acute and chronic stress, often but not exclusively linked with thoughts of dying.

Methods: The sample consists of hospitalized psychiatric patients following a suicide attempt by self poisoning (attempters: n=30) and demographically similar psychiatric outpatients with no history of suicidal behavior (controls: n=30). We used: socio-demographic questionnaire, Life Events Stress Scale, Pierce Suicide Intent Scale, CES-D, HAMD, DSQ-40.

Results: For attempters motives for suicide are abandonment of the loving partner, loneliness, quarrels with their parents. Before the suicide attempt, the most of them wanted to escape from unbearable situation, some of them lost control, other had a need for getting help of a loving person. Comparing with outpatients, attempters express suicide risks factors (SIS=4.5) and depression of medium level (CES-D=29.67±7.99) and use defensive mechanisms: immaturity (projection, dissociation, devaluation, acting-out) and a neurotic (altruism). The most of them (90 %) felt relief that a suicide had not succeed, but half of them intend to repeat a suicide.

Conclusion: It is pointing strongly to the fact that suicide attempters need a psychiatric intervention in crisis directly after a suicide attempt in order to reduce some of the burden and stress.

13. Liliana Dell’Osso¹, Dr., MD

Aims/Objectives:
We aimed to investigate the relationship between the presence and severity of depression and the degree of physical and functional disability in PD.

Methods:
We consecutively enrolled 122 PD outpatients: 65 satisfied DSM-IV criteria for major depression (PD-D); 57 non depressed PD subjects (PD-C) were matched for age, gender and duration of PD. Depressive symptoms were rated with the Hamilton Depression Rating Scale (HAM-D). The presence of motor symptoms (tremor, rigidity, instability, on-off phenomena and dyskinesias) was collected. Activities of daily-living (ADLs) and motor symptoms were measured by the Unified PD Rating Scale (UPDRS) part II and III. PD severity was staged by the Hoehn and Yahr system (H/Y).

Results:
Depression severity was staged by the HAM-D total score: 8-17 (mild depression, n=29); 18-24 (moderate depression, n=30); ≥ 25 (severe depression, n=6). Statistically significant differences between the groups were found for UPDRS II (p= .041) and III score (p= .007), Hoehn and Yahr score (p=.020), the presence of tremor (p=.029), instability (p=.030), and dyskinesias (p=.006), and duration of L-Dopa therapy (p=.000). Post-hoc analyses showed that in UPDRS II, III and Hoehn and Yahr scales patients with severe depression reported significantly higher scores than PD-C and patients with mild depression; moreover, patients with moderate depression scored significantly higher than PD-C and subjects with mild depression in UPDRS III and Hoehn and Yahr scales.

Conclusion:
Our findings suggest that the presence and the severity of depressive symptoms can significantly impair wellbeing and motor functioning in PD.

AMBIVALENCE AND BIPOLARITY: A SOCIAL PSYCHIC TRAUMA, LETHAL INHERITANCE OF THE PUNISHMENT.

INSTITUTIONS
1. CENTRO DE INVESTIGACIÓN, DIFUSION Y PROMOCION DE LA LIBERTAD INTERIOR, RESEARCH, TRUJILLO, Peru

AUTHORS
1. Armencio Delo¹, DR., armencio_delo@yahoo.com

Objective: Demonstrate that such psychiatric pathologies, as aberrant process, are not a genetic disease.

Method: Planned introspection, and meticulous evolved record of all internal conflicts triggered after the tireless search of the I, during 30 years.

Results: The punishment applied to a child divides the reality in 2 parts: Things that are allowed and prohibited, good and bad, obedient and rebels, Social Mold (SM) and Natural Mold (NM); the exercise of the SM produces the Reward and the practice of the NM to the Punishment, this allows the coexistence of 2 antagonistic laws under a single skin. The Social Law, of cerebral record, where EVERYTHINg DEPENDS ON A PARTICULAR ELEMENT and the Natural Law, fixed in his meats, of inverse direction, which gives origin to a dissociation or divorce among the objectives of the body and those of the mind.

Conclusion: The preceding results generate a change in the interpretation of reality, the things that are positive for the evolution of the Being - as the freedom, self-conduction, relaxation and exercising of the own will – become negative and the practice otherwise, positive; due to that, every wish, attitude or social feeling possesses a dual significance: ORIGIN OF EVERY AMBIVALENCE AND BIPOLARITY.

7. Satrupa Tyagi1

Objective- The study describes the development of an instrument that will be useful for screening the general population for suicide ideation and related behaviour. The reliability and validity of this instrument are also studied and described in the study.

Methodology- The items of the instrument were compiled by a multidisciplinary team, translated into the local language and administered to 10 respondents in the field and appropriate changes were done in the content of the instrument. Finally inter-rater, test-retest reliability and validity exercises were done on 172 adult subjects in the outpatient department of psychiatric hospital.

Analysis- Data entry and analysis was done using SPSS statistical software. Kappa coefficient was calculated to measure the degree of agreement between the two raters (inter rater). The findings of one research staff was compared with the findings of the consultants (gold standard). Two by two cross tables were prepared that provided sensitivity, specificity, positive predictivity & negative predictivity of the constructed instrument.

Results- The reliability exercise reveals a total inter rater agreement (Kappa value 1) and modest degree of test re-test agreement (kappa value 0.66). The validity exercise has shown that the instrument has high sensitivity (1.0) and modest specificity (0.67) indicating the ability of this instrument to recognize those with or without suicidal ideation in the community.

Conclusion- Fairly high indices of reliability and validity indicated suitability of the instrument for the assessment of suicidal ideation in the community.

The frequency of suicide has increased in the last years, in Latin American countries. In order to know the profile risk, we have designed an investigation in patients attended in the Emergency Room of a Multipurpose National Hospital on the outskirts of Buenos Aires. Material and Methods: People who has attempted suicide have been studied in the Hospital, Emergency Room, during a period of 6 months. The diagnosis was attempting suicide. At the same time, a control group was designed. A semi structured interview was used, made by a professional of the health. A statistical analysis by Multiple Regression took place.

The objective was to know the factors of self-destructive behaviours and their biopsychosocial predetermining risk, to the aims to make prevention strategies. Suicide was the main cause of mortality in mental health field. Knowing risk factors would be a way to precocious detection of the idea of suicide and suicide itself. Suicide attempt - risk factors

Objective: To extend knowledge of the time course of symptom improvement of patients with major depression (MDD), panic disorder (PD), social anxiety disorder (SAD) and generalised anxiety disorder (GAD) participating in randomised placebo-controlled trials (RCTs); and to infer the optimal duration of initial escitalopram treatment in clinical practice, after which subsequent intervention might be reasonable.

Method: Post-hoc analysis was made of the pooled clinical trial database for escitalopram in MDD (14 studies), GAD (4 studies), SAD (2 studies) and PD (1 study). Onset of action was defined as >=20% decrease from baseline: ‘response’ was defined as >=50% decrease from baseline.

Results: For patients with MDD, there was a 43% probability of achieving response at Week 8 if no onset was apparent at Week 2, whereas for patients demonstrating an onset of treatment effect at Week 2, this probability was nearly 80%. Similar patterns were observed in RCTs in GAD, SAD, and PD. If no treatment effect had occurred by Week 2, the chance of patients with MDD, GAD, or SAD responding after Week 4 was 20% or less. In patients with PD and no onset of response by Week 6, findings from the small number of patients suggest that continuing existing treatment had little clinical utility.

Conclusion: The pattern of response seen in these RCTs may suggest that for patients with MDD, GAD and SAD seen in wider clinical practice, a period of at least 4 weeks is worthwhile before a change in the therapeutic approach is considered.

DOES A DIAGNOSIS OF DEPRESSION INFLUENCE HYPNOTIC USE IN PRIMARY CARE?

INSTITUTIONS
1. Liverpool John Moores University, School of Pharmacy & Chemistry, Liverpool, United Kingdom
2. King’s College, Institute of Psychiatry, London, United Kingdom

AUTHORS
1. John Donoghue
2. Malcolm Lader

Aims
UK prescribing guidelines, which state that benzodiazepines should be used to treat insomnia only when it is severe and for a maximum period of 4 weeks do not acknowledge the need to manage disturbed sleep in depression, which may persist after clinical remission. This study investigated the impact of a diagnosis of depression on hypnotic prescribing in primary care in the UK.

Method
Data from 1996-2005 were obtained from the DIN-Link database (>750,000 patients). Patients (>18 years) who received a new prescription for a hypnotic (no prescriptions for any benzodiazepine in the previous year) were included and followed for 1 year. Data were obtained on gender, age, diagnosis of depression and length of treatment.

Results
The number of patients newly prescribed a hypnotic fell by 30% while those who received a diagnosis of depression increased from 11.1% to 17.4%. Throughout the study, a diagnosis of depression was associated with (i) an increase in the average length of hypnotic treatment, and (ii) increases in the proportions of patients continuing hypnotic treatment for more than 3 months or 1 year.

Conclusions
In patients newly prescribed a hypnotic, a diagnosis of depression increases the length of hypnotic treatment. Disturbed sleep in depression may be intractable and prescribing guidelines on the use of hypnotics do not meet the needs of depressed patients.

Depression can cause sexual disturbances and vice versa - sexual disturbances may become a cause of depressive disorders.

Objective of this investigation was distinguishing of totality of significant constitutional-biological factors for identification of prognosis, course and development of methods of treatment of comorbid depressive and sexual disorders. In clinics of SI Mental Health Research Institute TSC SB RAMsci we examined 70 men with comorbid depressive and sexual disorders, at the age 25-65 years. Examination was conducted with psychopathological method, method of structural analysis of sexological disorders, with statistic method. Three typological variants of depression have been distinguished: "vital depression", characterized by anguish and apathy (27%), "reactive depression", characterized by relevant psychogenic experiences (29%), "depression of exhaustion", for which asthenic, psychosomatic manifestations is typical (44%). In mild (HDRS - 10 scores; 48%) and moderate (HDRS - 16 scores; 32%) depressive disorders, sexual dysfunctions may be regarded as general clinical radical in depressions in males and their prevalence constituted up to 80%. They manifested through decrease of libido (80%), erectile dysfunctions (58%), ejaculator (21%) and orgasmic disturbances (10%). In severe depressive states (HDRS - 25 scores; 20 % of patients) sexological disturbances withdraw, sexual life disactualizes. After recovery of mental state, in depressive patients sexual disturbances often remain. In this association, program of treatment and rehabilitation of patients with comorbid depressive and sexual disorders has been developed with the use of antidepressant therapy, psychotherapeutic complex and preparation LEVITRA (vardenafil) allowing realizing principle of complex biopsychosocial model considering this pathology as multi-factorial disorder.

At the end of 90's of last century, in etiologic researches of neuropsychiatric disorders, are appearing studies which disclose outstanding connection between Sydenham’s chorea, movement disorders in childhood caused with rheumatic fever and obsessive-compulsive disorders. Accordingly, it is more spoken about possible autonomous mechanism of genesis and role of a hemolytic streptococcus in OCD etiopathogenesis. In 1998 Swedo and fellows are documented poststreptococcus OCD cases and/or tics to children and adolescents, without symptoms Sydenham’s chorea, called it as acronym PANDAS (the Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal infection). Neuroimaging researches are discovering the striatum increasing to these patients. In the following researches, behind comparing with OCD signs, PANDAS is connecting with emotional liability, separation anxiety, conductive disorders, cognitive deficit, motoral hyperactivity and eating disorders. In our research we are representing a development of polymorphous psychical disorders to 12-years-old girl, where in actual clinical presentation obtains restrictive type of anorexic phenomenology with compulsive symptoms. Key words: PANDAS, OCD, anorexia.

AUTHORS
1. Roman Duncko, dunckor@mail.nih.gov
2. Jian-Ping He, hejian@mail.nih.gov
3. Kathleen R. Merikangas, merikank@mail.nih.gov

Background: Although numerous studies have investigated the neuroendocrine activation during psychosocial stress in patients with anxiety and/or depression, only limited information is available on physiological activation during exercise stress. The present study analyzed the cardiovascular activation during a submaximal exercise test implemented in the National Health and Nutrition Examination Survey (NHANES).

Method: The sample includes 770 subjects from the nationally representative NHANES surveys (1999-2002) who were interviewed regarding 12 month DSM-IV mental disorders based on the Composite International Diagnostic Interview and participated in the exercise test. During the treadmill exercise test, blood pressure and heart rate were measured at the end of a 2-minute warm-up, two 3-minute exercise stages and the 1st, 2nd and 3rd minute of recovery. Repeated measures regression analysis was used to evaluate the relationship between major depressive disorder and anxiety disorders (panic disorder or generalized anxiety disorder) and cardiovascular activation during exercise adjusting for age, gender and the exercise protocol. The statistical program SUDAAN was used to account for stratification and clustering of the multistage NHANES sampling design in calculation of standard errors and test statistics.

Results: The analysis revealed a significant time*group interaction with the anxiety group but not the depression group exhibiting a significantly greater increase in systolic blood pressure at exercise stage 2 than controls ($X^2{1}=4.81; p=0.028$).

Conclusion: The present data indicate that anxiety is associated with increased cardiovascular activation during exercise, whereas no such pattern is present in the depression group. These findings extend our knowledge about stress response in anxiety and depression.

“THE PRODIGAL SON”: DOES GALVANIC SKIN RESPONSE ISOLATE OBSESSIVE COMPULSIVE DISORDER FROM ANXIETY DISORDERS?

INSTITUTIONS
1. Vikananda Institute of Medical Sciences, Psychiatry, Kolkata, India
2. Apollo Gleneagles Hospital, Psychiatry, Kolkata, India

AUTHORS
1. Partha Dutt, drparthadutt@yahoo.co.in
2. Debashis Ray, dr., mindhealth@gmail.com

Aims and Objectives: The galvanic skin resistance reduces in arousal and, hence, in anxiety. Obsessive compulsive disorder has been classified as an anxiety disorder in DSM-IV-TR. The present study aimed to compare of galvanic skin response in obsessive compulsive disorder, generalized anxiety disorder and normal subjects.

Methods: The galvanic skin response (GSR) was measured in 30 patients of generalized anxiety disorder, 30 patients of obsessive compulsive disorder who met DSM-IV-TR criteria and in 30 normal volunteers. Brief Psychiatric Rating Scale (BPRS), Yale-Brown Obsessive Compulsive Scale (YBOCS), Hamilton's Rating Scale for Anxiety (HRS-A) and Structured Clinical Interview for DSM-IV (SCID-P I) were used.

Results: The galvanic skin resistance was higher in obsessive compulsive disorder but lower in generalized anxiety disorder than in normal controls. The differences were statistically significant.

Conclusions: The markedly contrasting response to GSR in obsessive compulsive disorder and generalized anxiety disorder possibly indicate two distinct etiopathological, biological and phenomenological correlates. Other anxiety disorders also show a reduced galvanic skin resistance like generalized anxiety disorders. Does this mean that obsessive compulsive disorders merit a deeper nosological evaluation? This and other related issues will be discussed.

3. K. Sahli³, Dr., MD
4. Rajaa El Hedda³, Dr., MD
5. Béchir Ben Hadj Ali¹, Pr., MD, bechir_benhadjali@yahoo.fr

Stress of health care work appears to precipitate diagnosable mental disorders such as depression and anxiety. However, few studies reported prevalence and work condition correlates of specific disorders in samples of health care workers.

Objective: This study aimed to determine prevalence and work condition correlates of generalized anxiety disorder (GAD) in a representative sample of Sousse general hospital nurses.

Methods: A representative stratified and systematic sample of nurses working at University Hospital Farhat Hached of Sousse was constituted (N=228). Assessment was based on an interview with GAD section of CIDI Tunisian version. Data was treated with ishell program to have GAD diagnosis according to ICD-10 criteria and then exported to SPSS for statistical comparisons. Additional information related to demographic characteristics, past medical history and work conditions were also collected. Results: 4.4 % (n=10) of interviewed nurses fulfilled ICD-10 criteria of GAD. No differences in demographic characteristics, neither in medical antecedents were noticed between nurses with and without GAD. However, psychiatric history and past psychiatric care were more frequent in GAD group (p<10^-4), with more frequent (p<10^-4) and longer sick leave (10.83±51.87 vs. 50±112.08 days, p=0.030). Work related factors associated to GAD were longer commuting (p=0.003) and low satisfaction of interpersonal conditions.

Conclusion: GAD seems to induce more frequent and longer sick leave among nurses. Involved work factors were commuting and satisfaction level of interpersonal conditions. These factors should be considered in helping nurses cope with work stress or reducing work stress levels to prevent the occurrence of clinically significant anxiety.

STIGMA AND THE ROLE OF CULTURE IN THE HELP SEEKING BEHAVIOR AND DEALING WITH MOOD DISORDERS: RURAL VERSUS URBAN SURVEY STUDY IN A SAMPLE OF NILE DELTA OF EGYPT

INSTITUTIONS
1. Mansoura University Hospitals, Psychiatry, Mansoura, Egypt

AUTHORS
1. Mohammed Ezzat El-Hadidy¹, Dr., DD, mz_hadidy@hotmail.com
2. Mohammed El-Hosieny Khater¹, Dr., MD
3. Mohammed Abo El-Hoda¹, Dr., MD
4. Mohammed El-hadidy¹, Dr., MD
5. Warda Abo El-Ezz¹

Objectives: This was done to survey the effect of cultural beliefs in various patterns of help seeking behavior among sample of rural versus urban mood disorder's patients.

Design: Multistage random sampling technique was used to select two rural and two urban geographical areas in one of the Nile Delta governorates. A survey was done using MINI International Neuropsychiatric Interview (Arabic version). All adult mood disorder's patients who diagnosed according to DSM IV-R criteria were interviewed for their attitudes and help seeking pattern regarding folk and faith healers, primary car, physicians and psychiatrists.

Results: Most of the sample attribute their mood disorder problems to external influences or deny its existence rather than attributing it to a real disorder. Only 13% of cases visited professionals as the main line for help seeking behavior. Also, only 16.7% were unbeliever in faith or folk management. Meanwhile, 33.7% and 19.0% of the rural and the urban patients respectively, utilized faith and/or folk healing as the main pattern. Most of those (62.1%) were not yet asked any for professional help. Also, 25.0% of them utilized both lines of the help seeking simultaneously. The pattern of dealing with patients by the healers was always the same in spite of the diagnostic difference.

Conclusion: Current religious beliefs and traditional healers have strong influences, hardly to be nullified, in shaping of the management modalities of mood disorders among Egyptians patients specifically from rural areas.

2. Mieta M. Hategan², Dr., MD, hateganmieta@yahoo.com
3. Ileana I. Enatescu³, Dr., MD, ileana_urdas@yahoo.com

Aims/Objectives: Depression is among the most prevalent psychiatric conditions in the world. Medical co-morbidity is high prevalent in depressive patients. Our main purpose was to find the clinical and psychological factors that have influences somatic diseases occurrence in unipolar depressives.

Methods: We performed a cross-sectional study on 45 patients with Depressive recurrent disorders according with ICD-10 diagnostic criteria. The inclusion criteria consist in diagnostic of recurrent depression and age range between 18 and 65 years. Along with an original research datasheet for collecting clinical and paraclinical data, we use more standardized scales to asses depression (HDRS), anxiety (HAM-A), personality (dimensional - KSP and categorical – PAS-I) and coping styles (COPE).

Results: Studied sample consists in 45 subjects, 44% males and mean age = 51 yrs (SD=7.94). Depressive patients with A and B clusters of personality disorders was at the high risk to develop medical co-morbidity, especially for cardiovascular diseases ($\chi^2=7.799; p=0.02$) and general medical co-morbidity ($\chi^2=11.60; p=0.003$). Those having somatic comorbidities (general and cardiovascular) have had high scores for aggressivity and somatic anxiety related Karolinska scales. Levels of anxiety were significant correlated with somatic comorbidity ($p=0.049$). High psychoactive substance use and low level of acceptance were the most prominent coping styles in those having somatic diseases.

Conclusions: Depressive subjects are at the high risk to develop somatic co-morbidity. Personality particularities and coping modalities are important key factors that could influences somatic diseases occurrence in patients with unipolar depression. Hence, we must pay attention in exploring of these factors.

4. Pilar Gamzo³, Dr., MD
5. Gagan Joshi³, Dr., MD, gjoshi1@partners.org
6. Janet Wozniak³, Dr., MD, jwozniak@partners.org

Objectives: To describe the phenomenology and clinical course of pediatric BP in a European sample, to validate the diagnosis and to analyse risk factors.

Methods: We retrospectively reviewed the medical records of all children and adolescents (N=38) with DSM-IV Bipolar evaluated in Child & Adolescent Psychiatry Unit at the University of Navarra from 1999 to 2005. We used the NIMH Lifetime Mood Chart and the Clinical Global Impression.

Results: 79% (n=30) were boys and 21% (n=8) were girls; 44.7% (n=17) had BD-1, 5.3% (n=2) BD-2, 31.6% (n=12) BD-NOS, 15.8% (n=6) BD-3, and 2.6% (n=1) BD-4. Median (IQR:Q25;Q75) age at diagnosis was: 13.9 (10.6;15.8). Delay of diagnosis was: 1.46 years (0.65;3.41). The most frequent mood symptom at the time of diagnosis of BP was irritability (94.6%). 92.1% of the children had at least one comorbid disorder. We found higher rates of hospitalisation in children with ADHD (21%) (p<0.05). Children with Substance Abuse (18.4%) needed more current drugs (p<0.05). Median follow-up period was: 2.6 years. Percentage of time on an episode was: 46.17% (23.36;75.26). This was longer in younger children (p<0.05). 2.6% were rapid cycling. At the end of follow-up only 47% achieved remission or recovery. Younger children showed a worse response (p<0.05).

Conclusion: This sample of Bipolar Children in Europe closely resembles those described in U.S. clinics. Delay of diagnosis and misdiagnosis may explain low prevalence outside of the U.S. Bipolar can be diagnosed in children using DSM-IV criteria. An early age at onset and ADHD comorbidity are worse prognosis risk factors.

RELATIONS BETWEEN GENDER, AGE AND METHODS OF SUICIDE ATTEMPTS

INSTITUTIONS
1. Fukuoka University, School of Medicine, Department of Psychiatry, Fukuoka-City, Japan
2. Fukuoka University, School of Medicine, Department of Emergency and Critical Care Medicine, Fukuoka-City, Japan

AUTHORS
1. Nobuaki Eto¹, Dr., MD, etonobu@mac.com
2. Taisuke Kitamura², Dr., PhD
3. Keiichi Tanaka², Dr., PhD
4. Ryoji Nishimura¹, Dr., PhD

Objectives: The authors conducted a study of suicide attempts among the patients admitted to the emergency unit of Fukuoka University Hospital, which is located in an urban area in Japan. The goals were to determine the relations between demographic characteristics of those who performed suicidal actions and methods of suicide, and to investigate the lethality (the probability or likelihood of death) of each method employed in suicide attempts.

Methods: Clinical records were used to identify 293 consecutive suicidal patients of 301 admissions from April 2002 to March 2006.

Results: 1. Ingestion of drugs or poisons constitutes the method of first choice for both males (39%) and females (52%). Males tend to exceed females in hanging (22% and 10%, respectively). 2. Ingestion of drugs or poisons is the most commonly employed by most age groups (except 50's). In 50's group, hanging is the most prevalent. Some interesting patterns emerge in the method of the second largest proportion in each age group. Jumping is more prevalent in younger (10's - 40's) than in older suicidal patients, and hanging is more common in older (over 50's) than in younger patients. 3. The probability of death for each method resulted in the following order of methods by lethality: hanging (84%), jumping (48%), gas (22%), cutting or piercing instruments (6.7%), ingestion of drugs or poisons (4.4%).

Conclusions: We found that males have tendency to utilize more lethal methods, jumping is more prevalent in younger (10's - 40's) patients, and hanging is more common in older (over 50's).

5. Thomas Dresler¹, Mr., Dresler_T@Klinik.uni-wuerzburg.de
6. Juergen Deckert¹, Prof. Dr. med., MD, Deckert_J@Klinik.uni-wuerzburg.de

Background: Current research in patients with anxiety disorders suggests functional deficits within the prefrontal cortex, which result in reduced inhibition of the amygdale, in turn accounting for increased fear perception in these clinical populations.

Methods: Principally, such a pathophysiological model would allow to positively influence the supposed prefrontal hypofunction via repetitive transcranial magnetic stimulation (rTMS) in a facilitating mode (high-frequency stimulation). Such a facilitating treatment may strengthen the inhibitory activity of the prefrontal cortex, resulting in a better control of panic-associated amygdale hyperactivity and, in turn, in a reduction of panic attacks. Based on this theoretical framework, we propose the application of a non-invasive optical imaging technique (Near-Infrared Spectroscopy; NIRS) for the measurement of anxiety-related hypoactivity of the prefrontal cortex, and for the control of a treatment success on the brain metabolic level.

Results: In a single patient with panic disorder we could detect a pattern of hypoactivity in the prefrontal cortex during an emotional Stroop task. Facilitating rTMS treatment (15 sessions within three weeks, add-on) was associated with (1) an improvement of prefrontal activity in the emotional Stroop task and (2) with the absence of further panic attacks. This is the first report of a NIRS-guided and -controlled facilitating rTMS treatment of a patient with a panic disorder.

Conclusions: Given the excellent clinical applicability of the methods, the combination of NIRS and rTMS might have the potential to establish new treatment options in psychiatry aiming on the modulation of pathological regional brain activity patterns.

4. Gabor Faludi, Prof, MD, PhD

Background: Several studies have reported on neuropsychological deficits associated with major depression. Not all neurocognitive functions, however, are impaired in depressive patients. The aim of the present study was to measure and compare characteristics of neurocognitive functions of major depressive patients and healthy controls.

Method: Seventy-one patients with acute major depressive disorder were compared to thirty healthy control subjects on tasks measuring several aspects of cognitive functioning, such as attention, memory, executive function, psychomotor speed and visuo-spatial functions (Trail Making Test, Stroop Test, Rey Verbal Auditory Learning Test and Rey-Osterreith Figure Test).

Results: Depressed patients showed significantly impaired performance in tasks of attention, executive function, memory and psychomotor speed. In tasks measuring visuo-spatial function patients with major depression performed significantly better compared to controls.

Conclusion: In line with the result of earlier studies, our results indicate that impairment in several cognitive functions - selective attention, visual and verbal memory and learning - is characteristic of acute major depression. However, functions related to visuo-spatial construction appear to be untouched in patients with acute major depression, which suggests that hippocampal functions are intact in depressed patients. While deterioration in functions related to attention, memory and learning can be considered symptoms of general cognitive decline accompanying the acute phase of major depression, unimpaired visuo-spatial skills, which indicate intact hippocampal function can be considered a cognitive marker of major depression. Our study sheds light on the relationship between dysfunctional neuronal circuitry in the background of cognitive processes and depressive symptoms.

1. Mashhad University of Medical Sciences, Psychiatry, Mashhad, Iran (Islamic Republic of)

AUTHORS
1. Mohammad Reza Fayyazi Bordbar, Dr, MD, drfayyazibordbar@gmail.com
2. Atiefeh Soltanifar

Introduction: Objective of the present study was to evaluate the effect of family education on annual relapse of BMD-I.

Method: 60 patients with BMD-I who were hospitalized in Ibn-e-sina Psychiatric hospital of Mashhad were randomized to 2 groups. In One group families of patients received the education about the Psychiatric disorder, type and duration of treatment & aggravating factors. In the other group, families didn’t receive the education. Follow - up of patients was dose for one year, in 3 months intervals, in terms of treatment compliance, psychiatric visits, occupational, academic, interpersonal & individual function. The data was analyzed with t-test and Man - withy test.

Results: 57 patients completed the trial. At Base-line visit there was no significant difference between 2 groups in terms of Demographic characteristics, duration of disorder & type of medicates (P>0.05). In the group who received the education, there were 4 cases with relapse (13.7%) and in the control group 9 cases (31.58%) experienced relapse of the disorder. Those results showed the significant difference between 2 groups in terms of relapse rate (p=0/006). The group with education had the mean time of 11.41 months with using medications. This mean was 9.14 months in the control group (p=0/000). There was also a significant difference between 2 groups in terms of psychiatric visit, interpersonal, occupational and individual functions.

Conclusion: Family education for Iranian patients with major psychiatric disorder such as BMD-I in the time of patients discharge from hospital can be helpful in reducing the relapse rate of these disorders.

Introduction: Obsessive-compulsive disorder (OCD) is an heterogeneous disorder. If it centers the Obsessive-compulsive Spectrum it may shares some features with other disorders, where one of them is Body Dismorphic Disorder (BDD). We intend to verify how BDD may interfere with clinical presentation and psychiatric comorbidities of OCD patients.

Method: This cross-sectional study compared 282 OCD patients to 48 OCD+BDD patients, focusing on some intrinsic and extrinsic clinical characteristics.

Results: At the logistic regression model, OCD+BDD group more frequently showed social phobia, skin picking and Tourette Disorder. The severity of anxiety and depression according to Beck scales were higher for OCD+BDD group, that also presented more frequently somatic obsessions and compulsions of ordering and hoarding. YBOCS did not show differences between groups.

Conclusion: BDD associated to OCD may alter clinical presentation of OCD, stressing its heterogeneous presentation.

Introduction: Obsessive-Compulsive Disorder (OCD), as a heterogeneous disease, may influence individual personality features. Dimensional strategies may help to identify more homogeneous groups of OCD.

Method: This cross-sectional study intended to evaluate how intrinsic OCD phenomena could influence on aspects of temperament and character. Temperament and Character Inventory and Dimensional Yale-Brown Obsessive-Compulsive Scale were applied to 50 OCD patients diagnosed according to DSM-IV.

Results: Patients with aggressive and sexual/religious obsessive-compulsive dimensions showed higher scores on persistence; symmetry/order showed higher scores on harm avoidance and lower on self-directness and cooperativeness; contamination/washing showed higher scores on harm avoidance. The sample also showed that as higher the scores of DYBOCS, lower the scores on self-directness. Anxiety and depression may be confounding variables on novelty seeking, harm avoidance and self-directness.

Conclusion: Obsessive-compulsive symptoms content, the intensity of OCD and of the anxiety and depressive symptoms seems to have some influence on temperament and character of OCD patients. Prospective studies on temperament and character of OCD patients, with response to treatment evaluation, may be conducted.

LIGHT THERAPY AND FLUVOXAMINE IN THE TREATMENT OF DELUSIONAL DEPRESSION: A PILOT STUDY

INSTITUTIONS
1. Istituto Scientifico Ospedale San Raffaele - Turro, Department of Neuropsychiatric Sciences, Milan, Italy
2. Università Vita-Salute San Raffaele, School of Medicine, Milan, Italy

AUTHORS
1. Linda Franchini1, MD, franchini.linda@hsr.it
2. Danilo Dotoli1, dotoli.danilo@hsr.it
3. Fanny Bongiorno1, bongiorno.fanny@hsr.it
4. Simone Ballan2, s.ballan@mailstudenti.hsr.it
5. Cristina Colombo1, colombo.cristina@hsr.it

OBJECTIVE: The aim of this study was to evaluate the efficacy of chronobiological potentiation with light therapy (LT) to fluvoxamine in a sample of delusional depressed inpatients.

METHOD: 46 inpatients (14 bipolar and 32 unipolar) affected by a major depressive episode with psychotic features were treated with fluvoxamine 300 mg either with 30 minutes of light therapy (green and white) in the morning, or without.

RESULTS: After 6 weeks of treatment the percentage of remission was 63% (29/46); the group of patients treated with fluvoxamine and LT as adjunct treatment showed a HAM-D mean scores decrease since the second week of therapy (p<0.00285) in comparison with patients without the chronobiological potentiation treatment. No differences in DDDRS mean scores and no drop-outs for side effects or worsening in psychopathological conditions were observed.

CONCLUSION: In our delusional depressive sample the global percentage of recovered patients was 63% independently from the presence of the chronobiological potentiation with LT; we observed a significant enhancing effect using LT as potentiation strategy since the second week of therapy, confirming that a chronobiological approach could provide a global, marked and rapid amelioration.

AN OPEN-LABEL TRIAL IN 2050 ELDERLY OUTPATIENTS WITH DEPRESSION TREATED WITH ESCITALOPRAM IN A NATURALISTIC SETTING IN GERMANY

INSTITUTIONS
1. Klinikum der Ludwig-Maximilians-Universität, München, Germany
2. Institut für angewandte Statistik GmbH, Bielefeld, Germany
3. Lundbeck GmbH, Hamburg, Germany

AUTHORS
1. Hans-Jürgen Möller1, Prof.
2. Jörg Schnitker2, Dr.
3. Michael Friede3, Dr.

Objective: To assess the efficacy and tolerability profile of treatment with escitalopram under naturalistic conditions, in elderly outpatients (above 65 years of age) with depression.

Methods: 2050 patients completed 8 weeks of treatment with escitalopram in an open, multi-centre naturalistic study. Rating scales included a short version of the Montgomery-Åsberg Depression Rating Scale (svMAHRS) for the assessment of response.

Results: Most patients improved in their general state of health and showed a decrease in the severity of their depression. The majority (83.8%) of patients received 10mg/day escitalopram. The mean svMAHRS total score decreased from 31.9 (7.9) at baseline to 14.2 (8.5) at Week 8. On completion, 63.9% of the patients were responders (>50% decrease of svMAHRS total score from baseline) and 48.6% were remitters (svMAHRS<=12). Statistically significantly more patients aged <=75 years responded to treatment and achieved remission than those aged >75 years. Logistic regression, using stepwise backward elimination, was used to model response to treatment. Statistically significant positive factors were having a current episode <=1 month and duration of illness <=1 year. The diagnosis showed increasing responder rates from affective disorder (F31 or F34; odds ratio=1.00) over involutional depression (F03; odds ratio=1.68) and depressive episode (F32; odds ratio = 2.21) to recurrent depressive episode (F33; odds ratio=2.32). The differences between affective disorders and involutional depression were significant, while F32 and F33 showed no relevant differences in the responder rates.

Conclusion: This observational study corroborates the effectiveness and tolerability of escitalopram treatment of elderly patients in a naturalistic treatment setting.

NON-INTERVENTIONAL TRIAL IN OUTPATIENTS WITH COMORBID DEPRESSION AND ANXIETY TREATED WITH ESCITALOPRAM

INSTITUTIONS
1. Inn-Salzach-Klinikum, Wasserburg-Gabersee, Germany
2. Universitätsklinikum Freiburg, Freiburg, Germany
3. Lundbeck GmbH, Hamburg, Germany

AUTHORS
1. Gerd laux1, Prof. Dr.
2. Martin härter2, Prof.
3. Michael Friede3, Dr.

Objective: To investigate the effectiveness and tolerability of treatment with escitalopram under naturalistic conditions in outpatients with comorbid depression and anxiety disorders.

Methods: Patients with comorbid depression and anxiety disorders were treated 16 weeks with escitalopram (10-20mg/day) in an open, multi-centre naturalistic study. The effectiveness endpoints were the remission rate of the short version of the Montgomery-Åsberg Depression Rating Scale (svMADRS <=10), the HAMA (<10) and HADS-D (<10).

Results: This study comprised 2911 patients; 2371 with comorbid anxiety and depression, 284 with depression, and 188 with anxiety. 2270 patients were treated with escitalopram 10mg/day and 641 with 20mg/day. Approximately 69% of patients had severe depression (svMADRS >=30) at the start of treatment (baseline). Response to 16-weeks treatment is shown in the table: Parameter - Baseline - Week 16 - Remission rate svMADRS - 33.0±9.4 - 8.9±8.7 - 72.9% (N=2848) HAMA - 28.8±8.6 - 8.8±7.9 - 63.9% (N=2881) HADS-D - 29.6±6.4 - 10.7±7.8 - 55.2% (N=2776) 97.4% of the physicians and 96.1% of the patients rated tolerability as 'very good or good'. Adverse events were reported by 189 of 2907 patients (6.5%). In 157 patients (5.4%), the physician considered that there was at least a 'possible' causal relationship to escitalopram treatment. There were 17 patients with severe adverse events, of which 6 were possibly related to escitalopram. 109 patients (3.7%) prematurely withdrew due to non-compliance.

Conclusion: This observational study confirms the effectiveness and tolerability of escitalopram treatment of outpatients with comorbid anxio-depressive disorders.

AUTHORS
1. Hung Fu-Chien1, Dr., PhD, hfc@cycu.edu.tw
2. Chiu Chia-Ling1
3. Yeh Chin-Bin2

Background and purpose: Forgas proposed the dual-process mood-management model and provided evidence to support that individual's negative mood will turn to positive mood over time. According to Beevers dual process model, persistent dysphoria will be at risk for depression, and dysphoric mood mean that reflective processing does not adequately adjust biased associative processing. Depression vulnerability is associated with difficulty regulating negative mood states. The purpose of present study is to examine the role of spontaneous mood regulation in maintenance and relapse of depression.

Method: In the study, 11 formerly depressed patients (FD) and 10 currently depressed patients (CD) were recruited from out-patient. Another 10 never-depressed participants (ND) were recruited from community. After mood induction, the self-referent sentence completion task was completed (e.g. I). Then the rate of negative sentences of first and later half was compared with three groups.

Result. The study found that the ratio of negative sentences in FD and CD, were higher than ND significantly. In ND, the ratio of later half of negative sentences was lower than the first half of negative sentences. But in FD and CD, the part of the first and later half, the ratio of negative sentences is similarly.

Discussion: The study demonstrated that negative mood could be adequately adjusted in CD over time, but FD and CD did not. So, the ability of emotional regulation in ND was better than FD and CD. The implication of these results for the risk of maintenance and relapse in depression was discussed.

Glyoxalase-1 (Glo1) is an antioxidant enzyme which detoxifies α-ketoaldehydes to prevent the formation of prooxidant compounds, such as methylglyoxal, in all living cells. Glo1 has been suggested to be involved in anxiety disorders, autism, and Alzheimer's disease. However, little is known about the role of Glo1 in the pathophysiology of mood disorders, although mood disorders show a high rate of comorbidity with anxiety disorders. In the present study, we examined the expression levels of Glo1 mRNA in peripheral white blood cells of mood disorder patients to understand the role of Glo1 in mood disorders. Quantitative real-time polymerase chain reaction experiments revealed that reduced expression of Glo1 mRNA was observed in major depressive and bipolar disorder patients in a current depressive state, as compared with healthy control subjects. By contrast, in a remissive state, the expression of Glo1 mRNA in major depressive and bipolar patients showed no significant alteration when compared with healthy control subjects. These results suggest that reduced Glo1 mRNA expression is a state-dependent marker of both major depressive and bipolar disorders, and that the aberrant expression of Glo1 may be involved in the pathophysiology of mood disorders.

The purpose of this study is to investigate the relationship between the psychological symptoms with SSRI treatment and psychoneuroendocrinological indicators of saliva. Subjects were 10 outpatients with panic disorder. (male: 8, Female: 2) All patients were first episode and non-medicated. In order to assess the concentration of free-MHPG, cortizol and IgA, saliva was collected. Haminton's Anxiety Scale and POMS were used for psychiatric evaluation of panic disorder. Following the 5 weeks of Proxetine treatment (10mg/day), the saliva level of MHPG and cortizol were decreased, while the IgA was increased. Furthermore, these concentration saliva MHPG and cortizol were correlated with total HAS score, some items of HAS, POMS. These results suggested that clinical effects of paroxetine are mediated these psychoneuroendocrinological changes in panic disorder patients.

COMPARING THE PROFILE AND PRESENCE OF DEPRESSION AMONG NURSING STUDENTS FROM DIURNAL AND AFTERNOON COURSES

INSTITUTIONS
1. Escola de Enfermagem de Ribeirão Preto/USP, Enfermagem Psiquiátrica e Ciências Humanas, Ribeirão Preto, Brazil

AUTHORS
1. Antonia Regina Ferreira Furegato, Doutor, PhD, furegato@eerp.usp.br
2. Edilaine Cristina Silva, Doutor, PhD, nane@eerp.usp.br
3. Jair Licio Ferreira Santos, Doutor, PhD, jairlfs@fmrp.usp.br
4. Gabriela Carrion Degrande Moreira, Mrs, gabicdm@yahoo.com.br

This study aimed to identify the profile of students from two nursing courses (Bachelor - diurnal and Teaching Diploma - afternoon) verifying signs of depression and self-esteem levels, comparing these variables. A total of 114 students, properly informed, from the diurnal and afternoon courses at the College of Nursing at Ribeirão Preto participated in the study. The data search was obtained on known, valid and largely used instruments: Brazilian Economic Classification Criteria - CEB; Beck's Depression Inventory - BDI; Janis and Field's Self-Esteem Scale. The data, were submitted to analysis of correlation with significance level at 5%. The results show prevalence of 94 women (82.4%), 63% between 20 and 24 years old; 32.06% (Teaching Diploma) are older than 25 years and 32% (Bachelor) are younger than 20 years old; 69.6% (Bachelor) do not work, and 86.1% belong to classes A2 and B; 75.8% (Teaching Diploma) work and 67.4% from the total belong to classes B2 and C. The data show 15.4% (Bachelor) and 28.6% (Teaching Diploma) with signs indicative of depression (three severe cases in the afternoon courses). The self-esteem levels were classified in 97.4% as medium and high. None of the cases indicative of moderate and severe depression presented low self-esteem. The conclusion is that there are significant differences between the profiles of the two groups of subjects especially the higher incidence of depression among the Teaching Diploma students. It is possible that the prestige perceived in the academic context is a resilient factor, positively influencing the students' self-evaluation.

ANXIETY LEVEL AMONGST MEDICAL STUDENTS

INSTITUTIONS
1. Vardhman Mahavir Medical College, Safdarjung Hospital, New Delhi, India

AUTHORS
1. Rishi Gautam, Dr., M.B.B.S.
2. Kunal Bhatia, Dr., M.B.B.S.
3. Rohan Khandelwal, Dr., M.B.B.S.

OBJECTIVES: 1. To study the levels of anxiety amongst Medical Students. 2. To compare these levels with different variables and causative factors.

METHOD: Cross-Sectional study in a medical college using a standard anxiety questionnaire involving 310 medical students of all the batches currently studying in the college.

RESULTS: Out of the 310 medical students who participated in the study, 150(48.4%) were found to have high anxiety levels, which were comparable to a reference study. The prevalence of abnormally high anxiety levels was maximum in students belonging to the 3rd (66.1%), 5th (47%), 9th (49.3%) semesters. Anxiety levels were significantly higher amongst female students (61.3%) as compared to male students (43.2%) who were having high anxiety levels(p<0.05). Students living in the hostel had higher anxiety levels (56.1%) than students living at home(38.9%). 66.7% students cited Examinations as most important cause of high anxiety amongst them. No significant relationship was found between anxiety levels and their medium of schooling, or age.

CONCLUSION: The findings point towards very high prevalence of anxiety amongst medical students, with female students being more prone. Also, examinations instill enormous amounts of stress and anxiety which is clearly evident from very high anxiety levels amongst the students who had their examinations coming up (students belonging to the 3rd, 5th and 9th semesters)

USE OF A LONG-ACTING ATYPICALANTIPSYCHOTIC IN BIPOLAR PATIENTS

INSTITUTIONS
1. Larkfield Centre, Psychiatry, Glasgow, United Kingdom

AUTHORS
1. David G Gerber³, Dr, MBChB, MRCPsych, MBA, david.gerber@ggc.scot.nhs.uk
2. Aparna Wighe¹, Dr, MBBS, MRCPsych

Introduction: Adherence with maintenance treatment in bipolar disorder is poor (1), yet discontinuing treatment is the most frequent cause of recurrence. Conventional depot antipsychotics have been shown to reduce relapses in patients with frequent manic episodes (2,3), but are associated with more side effects, especially EPS.

Methods: An audit of eleven patients with bipolar affective disorder treated with RLAI was conducted. Demographic data and GAF scores were collected. Hospitalisation data was available for all eleven patients. The pre-treatment period was defined as the two years before starting RLAI. The RLAI treatment phase started from initiation of RLAI. If the patient was initiated on RLAI in hospital then the treatment phase was from the date of discharge.

Results: The primary reason for switching to RLAI was non-compliance with previous treatment (n=10). The average duration of treatment with RLAI was 1.98 years (range 0.5-4.5 years). RLAI was generally well tolerated. The mean GAF score at baseline was 36.3 and this improved to 66.9 following treatment with RLAI (n=8). The mean number of admissions during the pre-RLAI phase was 1.9 and this reduced to 0.9 during the RLAI treatment phase. The average number of days in hospital pre-RLAI was 157 days per patient, this reduced by 65 percent to 54.9 days per patient.

Conclusions: Treatment with RLAI is efficacious and combines the tolerability benefits of an atypical antipsychotic with the assured delivery of a long-acting injection. RLAI was associated with reduced hospitalisation.

EFFICIENCY OF THE THERAPEUTIC TREATMENT OF PTSD WITH DIFFERENT THERAPEUTIC METHODS

INSTITUTIONS
1. Clinic for Mental Health, PTSD Department, Niš, Serbia and Montenegro

AUTHORS
1. Grozdan Grbesa¹, Profesor Dr sci, MD PhD, grbesa@eunet.yu
2. Maja Simonovic¹, Mr Dr, MD

The purpose of the paper: The aim of the paper is to determine the efficiency of the therapeutic treatment of the PTSD. Methodology: The investigation comprises 86 patients with PTSD. The patients were divided in three groups that were treated by the different therapeutic methods. The first group was treated with the medicamentous therapy. The second group was treated by the analytically oriented group therapy and the third group was treated by EMDR in six to eight sessions once a week. The efficiency was measured by SCID-IV, CAPS, MADRS and HAMA.

Results: The results show significant global improvement with all three therapeutic methods, but of the different level respecting the parameters: psychic anxiety, somatic anxiety and depression. The results also show significant dependence of the duration of the period between traumatic event and treatment initiation.

Discussion: Traumatic events represents highly significant event with the strong emotional valence. Therapeutic treatment initiated in the period when traumatic memory was not consolidated and did not achieved stability which is manifested in the repetition of the symptoms, is not liable to therapeutic influence. This observation opens the problem of the methods, of the treatment and of the rapport with the traumatized in the first weeks of suffering after the traumatic event.

**AUTHORS**
1. Elena A. Grigoriev, Dr., Prof.
2. Natalia V. Yaltseva, Dr., PhD
3. Nikolay I. Korshunov, Dr., Prof.

1540 patients (aged 18–55) were screened. The risk of depressive disorders (according to specialized questionnaires) was identified in 778 (50.5%) patients. In general, it was respiratory, digestive, bone-muscular, endocrine (diabetes, II type) and blood circulation disorders. Only 517 (66.5%) patients agreed to visit a psychiatrist. Depression was revealed in 296 patients (HDRS score from 15 till 25, on the average - 18.6±0.24). Other psychiatric disorders associated with depression took place in 139 (26.9%) cases. The question of qualification and interpretation of the nature of depression (in general mixed: somatogenic, psychogenic, personal or genetic) in somatic patients according to DSM-IV is debatable. The polymorphism of depressive disorders and their propensity to endogenisation created diagnostic problems. The majority of depressions should be considered as desadaptation caused by severe somatic disease, where was traced definite time connection between disease debut or exacerbation and development of depression with sense of impossible to coping with current situation - 45.0% cases. Mild and moderate depressive episode - 30.4% of cases; adjustment disorder with mixed anxiety and depressed mood - 12.2%; organic disorder without psychotic features - 5.0%; major depressive disorder, recurrent, current moderate episode - 5.0%; other reactions on heavy stress - 4.4% of observations. Thus, the depression was suspected by therapist in 50.5% of screened patients, but only 19.2% of cases were confirmed by psychiatrist.

**AUTHORS**
1. Diogo F Guerreiro, MR, MD, dfiguerreiro@gmail.com
2. Manuel C Guerreiro, MR, MD, mcguerreiro@gmail.com

**Introduction**: The opsoclonus-myoclonus syndrome (OMS) is a rare condition, characterized by opsoclonus, a disorder of saccadic eye movements, associated with arrhythmic action myoclonus. The aetiology of OMS can be paraneoplastic or idiopathic. Outcome is variable, but motor symptoms and problems in behaviour, cognition, and attention typically persist. Specific antineuronal antibodies and inflammatory, degenerative changes have been described in the brainstem and cerebellum of adults with OMS. Dysfunction in cerebellar-cerebral circuits may underlie affective dysregulation and behavioural disturbances seen in OMS, as dysfunction of other cerebellar circuits underlie the movement symptoms.

**Case Description**: A 33-year-old female. Works as a school auxiliary. Diagnosis of idiopathic OMS at the age of 3, treated with ACTH therapy till the age of 8. Retained mild cognitive impairment, and speech slurring and imprecision, not being able to pursue her studies in faculty. She came to a psychiatric consultation at the age of 33, in which was observed a clinical syndrome of Obsessive-Compulsive Disorder (OCD). The patient presented intrusive egodistonic thoughts, related with the need to help animals, which converted into compulsive actions, she would spend most of her salary in food for abandoned dogs and, at certain time, she sheltered 4 abandoned dogs in her apartment. TC-Scan showed atrophy of the cerebellar hemispheres and the vermis. She began medication with fluvoxamine with reduction of OCD symptoms.

**Discussion**: Behaviour and cognition problems have already been described with OMS, in this case we observed adult OCD probably related with the brain damage, namely at the cerebellum.

2. Sibel Orsel1, Assoc. Prof., MD, sibelorsel@yahoo.com
3. Emre Sargin1, Dr., MD, emresargin79@yahoo.com

Aim: In this naturalistic and prospective study, we aimed to investigate the rates of remission and recurrence in a group of panic disorder patients and to determine the clinical predictors of recurrence.

Method: Sixty patients with Panic Disorder according to DSM-IV participated in the study. They were diagnosed by SCID-I and SCID-II. In all patients, a baseline and a follow-up with monthly evaluations of HAM-A, Panic Attack Questionnaire and CGI have been applied over a one-year period. All patients were treated with the drugs which had been prescribed by their clinician. At the end of the fifth year, we phoned for a clinical interview. The data were analysed by descriptive statistical tests and survival analysis.

Results: Thirty-six patients completed the study at the end of the first year. Among completers, the remission rate was 75% (n=27), the mean duration was 7.47 months. The non-remitted patients were significantly younger and had their first panic attacks before thirty years-old (respectively t= -2.5, p< 0.01; t= -2.7, p< 0.01). The anxiety and CGI scores were also significantly higher in non-remitted group through all the measures. Gender and personality traits were found non-significant. The remission rate at the end of the fifth year was 67.1% (n=18).

Conclusion: We found a clear difference between groups with respect to severity of symptoms. Our study results confirmed that the greater pre-treatment severity of anxiety and phobic symptoms reduced the rates of achieving complete remission of symptoms in PD patients although adequate treatment.

Objective: Poor outcome or higher severity of panic disorder (PD) is known if it is comorbid with agoraphobia (A). However, it is little known about relationship between panic attack (PA) and A in details. We investigated a relationship between the place of the first PA and comorbidity of A, severity and outcome of PD. Additionally, we examined the effects of the place where experienced first PA on frontal function during Word Fluency task using near-infrared spectroscopy (NIRS) as we have observed frontal dysfunction of patients with PD by NIRS during the cognitive task (Nishimura Y et al, 2007).

Method: The subjects were 860 patients with a DSM-IV diagnosis of PD who consecutively first visited Nagoya Mental Clinic, in Nagoya, Japan. We divided the patients into two groups based on comorbidity of A (PD with and without A groups) or place of the first PA (home and out of home groups). The association between place of the first PA and comorbidity of A was tested by a chi-square statistic. Some PD patients also participated in NIRS imaging study.

Results: Agoraphobia was more frequent in out of home group as compared with home group. Moreover, out of home group showed severer avoidance than home group. However no relationship between the place of the first PA and frontal function during the cognitive task was observed.

Conclusion: Our findings suggested that the place of the first PA predicted frequency of A comorbidity and severity of avoidance associated with the severity of PD, but the effect did not seem via frontal function.

COMPLEX PTSD, PSYCHIATRIC CO-MORBIDITY AND PHYSICAL RESPONSES - CASE STUDY

INSTITUTIONS
1. Dom zdravlja, Centar za mentalno zdravlje, Gracanica, Bosnia and Herzegovina

AUTHORS
1. Medin Hodzic¹, Dr., medin.h@bih.net.ba

Persons who survived cumulative traumatic experience develop symptoms that are more complex, diverse, wider and last longer than those who are described by the entity of PTSD. Of great importance is to approach seriously the problem of the co-morbidity of PTSD as most of the disorders increase the extents of the psychological disorders. Also, it is important to bear in minds that the combination of psychiatric disorders mostly leads to greater risk of suicide. By applying bad strategies to face traumas, persons often develop serious physical dysfunctions. In this case study I would like to speak about the factors that influence the (un)success in treatment, rehabilitation and re-socialisation of the patients suffering from PTSD. I am presenting the case of the patient with the clinical picture of the chronic PTSD, along with development of permanent personality disorders, complicated psychotic episodes with several serious attempts to commit suicide, with somatic symptoms fixed to the gastrointestinal and urine genital tract. From anamnesis: M.S. born in 1970, married, father of three children, and locksmith by vocation. M.S. had participated in the war since May 1992, manifested physical disorders have been reoccurring since July 1994. For the first time treated at the Psychiatric clinic in October 1994 due to the imperative heard hallucinations under whose influence he tried several times to commit suicide. Further disorders were restlessness, anxiousness, and cognitive blockade. Afterwards, was treated in psychiatric department 12 times, and due to the physical symptoms, 7 times in surgery and internal departments.

THE CZECH WRITER BOHUMIL HRABAL HAS COMMITED SUICIDE DUE TO DEPRESSIVE DISORDER

INSTITUTIONS
1. Masaryk Memorial Cancer Institute, Brno, Czech Republic

AUTHORS
1. Norbert Holub¹, MD

AIM: The world famous Czech writer Bohumil Hrabal (Closely Observed Trains, I Served the King of England) died in 1997 while he was hospitalized at the orthopedical department in the Prague hospital Na Bulovce: he leaped out of the window. The official statement reported death by misadventure and media mentioned the romantic dare of a great artist. The aim of this paper is the explanation of the real cause of Hrabal’s death.

METHODS: Using a medical perspective, we have revised many documents: Hrabal’s interview with Laszlo Szigeti, the autobiographical trilogy Weddings in the House, the authorized biography written by Monika Zgustova and memories of the writer’s friends. We have searched for notes of suicide, sadness, melancholy, insomnia, fear and anxiety and we have found, for example, this information about the first Hrabal’s depressive episode: “But Georgine has never come to us and my son sickened of this, half year he suffered from sleeplessness, he lost weight very much, it was a dying in the family.”

RESULTS: The result is unambiguous: Bohumil Hrabal suffered from depression and this disease was not diagnosticated. Hrabal’s death is an example of a tragical suicide caused by major depression.

CONCLUSION: It is well known that the prevalence of depression is high in the population of old people and some of those depressive seniors commit suicide. Unfortunately, there are a great number of patients whose depression is not recognized by somatic physicians. It is very sad that the excellent writer Bohumil Hrabal should be one of these patients.

THE BRAIN GLUCOSE METABOLISM DIFFERENCES BETWEEN BIPOLAR MOOD DISORDER AND UNIPOLAR MOOD DISORDER, DEPRESSED STATE AND EUTHYMIC STATE

INSTITUTIONS
1. University of Tokyo, Department of Neuropsychiatry, Tokyo, Japan
2. University of Tokyo, Department of Radiology, Tokyo, Japan

AUTHORS
1. Taiga Hosokawa¹, Dr., MD, taiga@medical.email.ne.jp

3. Kiyoto Kasai¹, Dr., MD

Aims: Functional brain imaging studies has consistently demonstrated abnormalities of regional cerebral glucose metabolism (rCMRglu) in prefrontal cortex in patients with mood disorder (MD). However, the metabolism difference between bipolar mood disorder (BP) and unipolar mood disorder (UP) has not been clarified. The present study was conducted to investigate it.

Methods: We used [18F]fluorodeoxyglucose (FDG) positron emission tomography (PET) to evaluate alterations of rCMRglu. We compare depressed and euthymic MD women patients with well matched healthy controls (HCs). Then, BPs and UPS were analyzed separately among MDS. The PET data were objectively analyzed by using statistical parametric mapping (SPM) methods.

Results: Compared with HCs, the depressed patients showed significantly decreased rCMRglu in frontal gyrus (left > right), temporal gyrus (left < right), insula (bilateral) and anterior cingulate (right). On the contrary, the euthymic patients demonstrated no significant differences. When the BP depressed patients were separately compared with HCs, the rCMRglu significantly decreased in frontal gyrus (left > right), insula (left) and anterior cingulate (right). Meanwhile, the UP depressed patients showed significantly decreased metabolism in frontal gyrus (left > right), temporal gyrus (left < right) and insula (bilateral).

Conclusion: The results of the present study provide evidences of persistent hypometabolism in depressed patients. The abnormalities tend to normalize as symptoms of depression improve. The present investigation also elucidated cerebral hypofunction specific to each BP and UP.

DOES BASELINE ANXIETY AFFECT OUTCOME OF SSRI TREATMENT IN PATIENTS WITH SEVERE DEPRESSION?

INSTITUTIONS
1. University Department of Adult Psychiatry, CHU de Montpellier and INSERM U-, Montpellier, France
2. H. Lundbeck A/S, Copenhagen, Denmark

AUTHORS
1. Jean-Philippe Boulenger¹
2. Anna Karina Trap Huusom²
3. Emmanuelle Weiller²

Background: To investigate if treatment outcome for severely depressed patients (baseline MADRS>=30) depends on their baseline level of anxiety.

Methods: A subgroup of patients with co-morbid anxiety (baseline HAM-A>20; escitalopram: n=144, paroxetine: n=142) was selected from a 24-week randomised, double-blind, parallel study in patients with a primary diagnosis of severe MDD (baseline MADRS>=30) comparing 20mg escitalopram (n=232) and 40mg paroxetine (n=227). Post-hoc analyses of efficacy were based on ANCOVA of change from baseline to endpoint (LOCF) and logistic regression analysis.

Results: At Week 24, the mean change from baseline in MADRS total scores was -24.1 for escitalopram-treated patients and -21.4 for paroxetine-treated patients (mean difference 2.7, p<0.05). The mean change from baseline in HAM-A total score was -17.4 for escitalopram-treated patients and -15.1 for paroxetine-treated patients at Week 24 (p<0.05). The proportion of remitters (MADRS<12 and HAM-A<7) after 24 weeks of treatment was 58.2% (82 of 141 patients) in the escitalopram group and 44.6% (62 of 139 patients) in the paroxetine group (p=0.01). Significantly more patients (p<0.01) withdrew from the paroxetine group (31%) than from the escitalopram group (17%). The main AEs leading to withdrawal were nausea (escitalopram versus paroxetine: 1 versus 4), insomnia (2 versus 2), and hyperhidrosis (1 versus 2). There were no statistically significant differences in the incidence of individual adverse events between treatments.

Conclusion: Patients with severe depression together with comorbid anxiety symptoms responded statistically significantly better to treatment with escitalopram 20mg compared with paroxetine 40mg, regardless of the severity of anxiety symptoms at baseline.

**Awareness of Illness in Subjects with Bipolar Disorder**

**Institutions**
1. Ar-razi Hospital Psychiatric, Psychiatric, Salé, Morocco

**Authors**
1. Nadia Chafiq, DR of Psychiatric, CN, chafiqnadia2005@yahoo.fr

Insight and awareness of disorder are an important domain for research and practice in psychiatry. Brought up by alienists long ago, the question of awareness of illness has once again struck psychiatrists because of its diagnostic and therapeutic implications. As we now dispose of dependable psychometric tools, using a short scale (eight items) easy and quick to use. This study included 11 euthymic bipolar subjects of which 14 seen at the hospitalization period (DSM-IV diagnosis) It shows that the degree of awareness is different according to the type of hospitalization (insight is significantly higher in free and voluntary hospitalization compared to compulsory hospitalization), in married patients compared to single patients, insight is significantly better if cognitive function is higher (MMSE score). Finally subjects who had recovered from a manic episode had the worse awareness. The probable persistence of infraclinical symptoms could explain the very close involvement and the deterioration of the insight scores. Awareness must be taken into account in all major mental disorders. Therapeutic alliance treatment compliance, prognosis and risk of relapse depend largely on this dimension.

1. Anita Chauvin, anita_is@iinet.net.au

There is a growing mental health workforce shortage making access to intensive psychotherapeutic interventions more difficult to achieve. The aim of this study is to develop a staged model of intervention which could be taught to clients for daily self-administration to address depression, anxiety, impulsivity, post traumatic stress disorder (PTSD) and increased risk of self-harming and suicide, resulting from prolonged exposure to violence, abuse and neglect in childhood. There is significant fMRI and physiological evidence that prolonged trauma can affect the developing brains of children and young people, with long term neurophysiological and neurochemical consequences. It has, however, also been demonstrated through fMRI that the brain remains plastic throughout life and the sequelae of trauma can be effectively corrected. fMRI studies of experienced meditators (Tibetan monks) and even of naïve meditators (a depressed cohort), have shown that sustained changes in brain function can be generated through a number of simple meditations, reducing the recurrence of depression, resetting the ‘default’ state to happiness (through generation of sustained left prefrontal cortex activity). Evidence suggests that different meditations can be applied to address different mental states and to develop the protective life skills which build resilience. This workshop examines the neurophysiological evidence and then guides participants through practicing a range of meditations and then facilitates discussion so that we can consider their applicability as an intervention for those with depression and other sequelae of trauma, eg anxiety, impulsivity, post traumatic stress disorder (PTSD) and increased risk of self-harming and suicide.

Objectives: The purposes of this study were to examine prevalence, characteristics and comorbidity of body dysmorphic disorder in a Korean nurse college students.

Methods: Korean versions of Body Dysmorphic Disorder Examination-Self Report (BDDE-SR), Maudsley Obsessional-Compulsive Inventory(MOCI), Beck Depression Inventory(BDI), Rosenberg Self Esteem Scale(SES), Liebowitz social anxiety scale(LSAS) were applied to 607 Korean nurse college students.

Results:
1) Five factors were extracted in BDDE-SR by factor analysis with the Varimax rotation. They were ‘preoccupation, distress, embarrassment factor’, ‘avoidance factor’, ‘checking, comparing, camouflaging factor’, ‘dissatisfaction factor’, ‘importance factor’.
2) Eighteen participants (2.97%) were satisfied with DSM-IV criteria a and b of body dysmorphic disorder(BDD Group).
3) The most dissatisfied body part was entire leg, eye, nose, waist-abdomen, calves in BDD group.
4) Differences between BDD group and non-BDD group on age and weight were significant by Mann-Whitney U test. 5) Differences between BDD group and non-BDD group on BDI, MOCI, LSAS-anxiety scale, LSAS-avoidance scale, SES were significant by Mann-Whitney U-test. 6)Difference between men and females on BDDE-SR factor 1, BDDE-SR factor 2, BDDE-SR factor 3, BDDE-SR total factors, LSAS-avoidance scale were significant by Mann-Whitney U- test. 7) Using multiple regression analysis the most contributing variance toward the total factor score of BDDE-SR of participants was BDI, and otherwise were BMI, LSAS-anxiety scale, SES in order of contribution.

Conclusion: These results indicate that BDD is a common disorder and is highly associated with depression, anxiety, obsessive-compulsive disorder symptoms, and poor self-esteem. We suggest that future researches should be directed to obtain clinical data of patients with BDD.

An important problem about the antidepressant response is the latency period, with the risks and suffering that it involves. Based on 30 patients diagnosed with major depression (DSM-IV), for this study we have used a new molecule, escitalopram, isomer S of the citalopram, the most powerful of the SSRIs, considering its good tolerance, the shortening of the latency period and its higher antidepressant effectiveness. The dosage used was 10-20 mg a day. To measure the response, the HDRS scale with 17 items for depression was used, measuring the response at the first, second and third week. We have found a better response in less time, from the seven initial days, with a good tolerance, and a response that improves during the following weeks (the first day the average of the HDRS was 20, and after a week it had come down to 16, and at third week to 12) These preliminary findings make us think of the importance of lowering the latency period of the antidepressants. This can change our praxis in a great number of depressed patients.

2. Beatrice Lai¹, Dr, PhD
3. D Ts Lee¹, Dr., MD

Aims: Validation study of EPDS on paternal depression in a Chinese population

Methods: A cohort of 608 couples were studied using EPDS, SCID and PHQ-9 longitudinally. Of these, 235 men completed SCID and EPDS at 8 weeks.

Results: At 8 weeks postpartum, 3.8 % had minor depression and 3.4 % had major depression by SCID questionnaire. 11.9 % scored above the cutoff point of 10/11 (optimal cutoff point) on EPDS. The AUC was 0.975. Specificity was 94.5 % and sensitivity was 95.1 %. PPV was 57.1 % and NPV was 99.5 %.

Conclusion: The psychometric properties of the translated EPDS appears to be equivalent to or slightly better in Chinese men compared to Chinese women.

Conclusions: a translated version of EPDS has been shown to be a useful tool for detecting paternal depression in the postpartum period.

3. Kiyohisa Takahashi², Dr., MD, PhD, ktaka@ncnp.go.jp
4. J-Misp Group³, strategy@minos.ocn.ne.jp

Suicide is a major public health problem and the number of suicide victims has exceeded 30,000 a year since 1998 in Japan. Suicide rate is almost 25/100,000, which are remarkably high numbers among advanced countries. During the past 50 years, Japan has undergone a structural reform from an agriculture-based to an industry-based economy. In addition, Japanese citizens aged 65 or older is expected to reach 26% in 2015, reflecting a recent rapid increase in the aging rate of the population. These factors could be threatening the success of suicide prevention in Japan. In 2005, The Japan Ministry of Health, Labour, and Welfare selected the Japan Foundation for Neuroscience and Mental Health (JFNM) as the primary institution responsible for the strategic research program for suicide prevention. JFNM are now conducting the program “Japanese Multimodal Intervention Trials for Suicide Prevention, J-MISP” tightly collaborating with the National Center of Neurology and Psychiatry. The research projects by J-MISP are as follows: (1) A community intervention trial of multi-modal suicide prevention program in Japan: A Novel multimodal Community Intervention program to prevent suicide and suicide attempt in Japan, NOCOMIT-J and (2) A randomized, controlled, multicenter trial of post-suicide attempt case management for the prevention of further attempts in Japan, ACTION-J. In 2006, the Japanese Diet approved the “Suicide Prevention Law”. We hope that the results of J-MISP research projects will help to develop effective strategies to reduce future suicide rate in Japan. (http://www.jfnm.or.jp/itaku/J-MISP/index.html)

COMORBIDITY OF BODY DYSMORPHIC DISORDER AND ANOREXIA NERVOSA IN PATIENTS WITH OCD

INSTITUTIONS
1. Yerevan State Medical University, Psychiatry, Yerevan, Armenia
2. Yerevan State Medical University, Psychiatry, Yerevan, Armenia
3. Yerevan State University, Psychology, Yerevan, Armenia

AUTHORS
1. Narine Israelyan, MD, narine-israelyan
2. Maruke Yeghiyan, Dr, PhD, narine-israelyan
3. Marine Tozalakyan, Mrs, narine-israelyan

Comorbidity of anorexia nervosa (2) and dysmorphophobic disorder(1) is very common during the OCD. In the different stages of pathological processes one of these overlap syndromes becomes permanent and implicate the diagnose. So it's necessary to make dynamic follow up of pathological process. Aim of the study is to examine the course and relationship of anorexia nervosa and dysmorphophobic ocd spectrum disorders among adolescents. We have made dynamic clinical study of 40 patients with OCD (aged 13-21). Studied cases were evaluated according to ICD 10 criterias. 12 of patients had dysmorphophobic disorders that preliminary observed in pubertal period. In 6 cases dysmorphophobia relate to imaginary weight problems and was observed along side with anorexia. In these cases anorexia had secondary character and distract to solve the weight problem. It was comorbid to dysmorphophobic disorder. In 2 cases anorexia was developed on the background of compulsive eating of non edible products. In these cases anorexia had defensive mechanism. In 2 cases anorexia was connected to obsessions on the basis of reasoning. In 3 cases anorexia had primary character being only based on eating compulsions (compulsive dieting without any purpose of weight control). In 2 cases dieting manifested as weight controlling process but then losts this purpose became compulsion at the late pubertal stage. Conclusion - Anorexia is based not only on eating compulsions, it can occur as a secondary being based on dysmorphophobia and reasoning. There is a cause and effect relationship between continuously overlapping from dysmorphophobia to anorexia in framework of ocd spectrum. References-

SUCCESSFUL SWITCHING TO QUETIAPINE IN PATIENTS WITH BIPOLAR DISORDER WHO WERE REFRACTORY TO OLANZAPINE

INSTITUTIONS
1. Wakayama Medical University, Dep. of Neuropsychiatry, Wakayama City, Japan

AUTHORS
1. Jun Iwatani, Dr., MD, iwatanij@wakayama-med.ac.jp
2. Masahiro Yamamoto, Dr., MD
3. Satoshi Ukai, Dr., MD, PhD
4. Tomikimi Tuji, Dr., MD, PhD
5. Kazuhiro Shinosaki, Dr., MD, PhD

Background: Although monotherapy with lithium or valproate is a recommended initial therapy for bipolar disorder, these agents are not always associated with prolonged favorable outcomes. Recently, increasing evidence has demonstrated the efficacy of combination therapy of mood stabilizers with atypical antipsychotics. However, the clinical indications of each antipsychotic are still to be studied.

Case presentation: We experienced 2 cases with bipolar disorder partially responded to co-therapy of mood stabilizers and Olanzapine. Switching from 20 mg/day of Olanzapine to 300-400 mg/day of Quetiapine reduced the manic and depressive symptoms quickly and remarkably, and prevented their recurrence. Case 1 is a 22-year-old woman in mixed mania. She received lithium, valproate, and 20 mg/day of Olanzapine for 8 weeks, but responded to them partially. Olanzapine was switched to 300 mg/day of Quetiapine, and then, she recovered in 3 days and has been free from mania. Case 2 is a 54-year-old woman in bipolar disorder suffering from depression with mood-congruent delusions and hallucinations. She responded partially to lithium and 20 mg/day of Olanzapine medicated for 12 weeks. By using 400 mg/day of Quetiapine combination with lithium, her depressive and psychotic symptoms were removed and haven't been recurred since then.

Discussions: While Quetiapine and Olanzapine share a wide range of targets such as serotonin, norepinephrine, dopamine, GABA, glutamate, and various second messenger signaling pathways, they differ in some pharmacological profiles. Those differences might be responsible for the quick remissiion of our cases. Further studies should be conducted to clarify the mechanisms of Quetiapine augmentation treatment.
A preliminary report

DECISION MAKING, WORKING MEMORY AND EXECUTIVE FUNCTION IN REMITTED BIPOLAR PATIENTS.

INSTITUTIONS
1. Nicolaus Copernicus University Torun, Collegium Medicum Bydgoszcz, Clinical Neuropsychology Unit, Bydgoszcz, Poland

AUTHORS
1. Marcin J Jaracz
2. Wiktor Drozdz
3. Alina Borkowska

Aims:
Decision making, as well as working memory and executive functions, are among the most significant cognitive processes, associated with prefrontal cortex function. Decision making is associated with the orbitofrontal cortex function. Working memory and executive functions are dependent on the dorsolateral prefrontal cortex. Orbitofrontal, as well as dorsolateral prefrontal cortex dysfunction in bipolar disorder has been reported. The aim of the study was to assess decision making and executive functions in remitted bipolar patients.

Methods:
The study included 10 euthymic bipolar patients (6 female, 4 male), aged 40±12 years and 10 age, sex and education years matched healthy controls. Decision making was assessed with Iowa Gambling Task (IGT). Working memory and executive functions were assessed with Wisconsin Card Sorting Test (WCST) and Trail Making Test (TMT). Depressive and/or manic symptoms were measured with Hamilton Depression Scale (HAMD) and Young Mania Rating Scale (YMRS).

Results:
No significant differences between cognitive performance of bipolar patients and healthy controls, except for the TMT a test (t=2.38, p=0.03) were found. A trend towards lower income and higher preference towards risky decks in IGT as well as worse performance in WCST tests in bipolar patients was observed. Conclusions: Bipolar patients performed significantly worse only on the TMT a test. A trend towards worse performance on other neuropsychological measures by bipolar patients was observed. Significance of this observation remains unclear due to a small number of subjects in the research.

CLINICAL CHARACTERISTICS AND IMPACT OF OBSESSIVE-COMPULSIVE DISORDER ON THE ANTI-MANIC RESPONSE IN YOUTH WITH BIPOLAR DISORDER

INSTITUTIONS
1. Massachusetts General Hospital, Boston, MA, United States

AUTHORS
1. Gagan Joshi, Dr., MD. gaganjoshi@hotmail.com
2. Janet Wozniak
3. Daniel Geller, Dr., MD
4. Eric Mick
5. Carter Petty
6. Joseph Biederman

Objective: To examine clinical characteristics of comorbid OCD and bipolar disorder (BPD) and to compare anti-manic response of BPD youth to olanzapine monotherapy based on comorbidity with OCD.

Methods: Secondary analysis of data from 18 years and younger OCD (n=125) and BPD (n=82) youth ascertained for family genetic study of pediatric OCD and BPD and from 8-week, open-label, olanzapine monotherapy trial of youth with BPD (n=52). Subjects were evaluated with structured psychiatric diagnostic interviews.

Results: 15% (n=19) of OCD and 21% (n=17) of the BPD youth fulfilled criteria for both OCD & BPD. Comorbid OCD & BPD youth had more frequent obsessions (56% versus 24%; p=0.003) and compulsions (63% vs 20%; p=0.001) of hoarding/saving. Anti-manic response was significantly worse in BPD subjects with OCD (39%; n=20) than without OCD comorbidity (mean reduction in YMRS score -6±13.1 versus -14±11.8; p=0.04). No difference observed when anti-manic response compared based on BPD subject’s comorbidity with GAD (YMRS score -11±13.7 versus -10±12.4; p=0.6).

Conclusion: Youth with comorbid OCD and BPD present with OCD symptom of hoarding/saving at a significantly higher frequency that may serve as a symptom marker for the risk of comorbidity with BPD. Anti-manic response of BPD is worse in the presence of OCD but not GAD comorbidity. Further studies in this direction are warranted.

SUPERIORITY OF ESCITALOPRAM OVER PAROXETINE IN THE TREATMENT OF MAJOR DEPRESSIVE DISORDER (MDD)

INSTITUTIONS
1. Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria
2. University of Southampton, Clinical Neuroscience Division, School of Medicine, Southampton, United Kingdom
3. CHU de Montpellier and INSERM U-888, University Department of Adult Psychiatry, Montpellier, France

AUTHORS
1. Siegfried Kasper¹, Professor, MD, sci-biopsy@meduniwien
2. David S Baldwin², Dr, MD, ddb@soton.ac.uk
3. Jean-Philippe Boulenger³, Professor, MD, jp-boulenger@chu-montpellier.fr

Objective: To compare escitalopram (10-20 mg/day) with paroxetine (20-40 mg/day) for the treatment of major depressive disorder (MDD).

Methods: Pooled data were analysed from two randomised, controlled, 6-month trials comparing escitalopram (n=394) with paroxetine (n=383) in patients with MDD. The primary endpoint was the mean change in MADRS score from baseline to last assessment.

Results: Escitalopram-treated patients showed a significant improvement from baseline in MADRS total score after 6 months compared to paroxetine (estimated mean difference 2.0 points, p<0.001). Further significant differences were seen for the CGI-S (mean improvement of 2.1 for escitalopram versus 2.4 for paroxetine, p<0.001) and the CGI-I (mean improvement of 1.8 for escitalopram and 2.0 for paroxetine, p<0.001). In severely depressed patients (MADRS ≥30), escitalopram-treated patients showed improved efficacy in all scales relative to paroxetine at last assessment. Significantly higher remission rates (MADRS ≤12, p<0.05) were seen with escitalopram and this difference extended to complete remission (MADRS ≤5, p<0.01). Escitalopram demonstrated superior tolerability with significantly fewer withdrawals (17%) compared with the paroxetine group (28%, p<0.001) and significantly fewer withdrawals due to adverse events (7% vs. 12%, p<0.01). Response at week 8 was a strong indicator of the likelihood of completing 6-month treatment and of achieving complete remission.

Conclusion: This study demonstrates increased efficacy and tolerability for escitalopram over longer-term treatment periods when compared with paroxetine. For long-term or maintenance therapy of MDD and particularly in the treatment of severely depressed patients escitalopram improves therapeutic outcomes.

5. Sherry Liu⁵, PhD, 6. Martin Brecher³, MD, DMSc, MBA

Aims/Objectives: To evaluate the efficacy and tolerability of extended release quetiapine fumarate (quetiapine XR) once-daily monotherapy for maintenance therapy in patients with generalized anxiety disorder (GAD)

Methods: A time-to-event (maximum 52-weeks), double-blind, randomized-withdrawal, parallel-group, placebo-controlled study (D1448C00012) of quetiapine XR monotherapy following open-label stabilization for a minimum of 12 weeks. Patients received quetiapine XR: 4-8-week open-label; 12-18-week stabilization. Eligible patients (HAM-A ≤12; MADRS ≤16; CGI-S ≤3) were randomized to quetiapine XR or placebo at last open-label visit dose, that subsequently could be adjusted to 50, 150 or 300mg/day as clinically indicated. Primary objective: to evaluate the efficacy of quetiapine XR vs placebo in increasing time from randomization to an anxiety event according to predefined criteria. Secondary variables included risk of relapse of anxiety events and was generally well tolerated during maintenance treatment of patients with GAD.

2. Yasemin Simsek², Mrs, PHD
3. Ozgur Yasar Akbal³, Mr, MD
4. Guliz Erdem Yazici⁴, Mrs, MD

OBJECTIVE: The aim of this study is to investigate the frequency of AT in MVP and/or PD.

METHOD: Forty patients who were and found to have MVP with oscillation followed by two dimension echocardiography were involved to the study. AT were determined with TEMPS-A (Temperament Evaluation Memphis, Pisa, Paris, San Diego- Auto questionnaire) in 15 MVP patients with PD according to DSM-IV, 16 MVP patients with no diagnosis according to DSM-IV and 19 PD patients found to have no MVP.

RESULTS: The frequencies of AT were similar between MVP and MVP+PD groups (p=0.425) however this was less than presence in PD group (p=0.024). 10 patients in MVP group were found to have GAD (Generalized Anxiety Disorder) and 7 of them were found to also have AT. There were no difference between the frequencies of AT in MVP, MVP+PD and MVP+GAD.

CONCLUSION: The prevalence of AM in PD was similar to the healthy population however in the presence of MVP it was more frequent than the healthy population whether associated with PD or not. It was also frequent in MVP patients who were diagnosed to have GAD. MVP and AT may lead to tendency to anxiety disorders together. AT may help to explain the conflicting results in the studies dealing with the interaction between MVP and PD.

5. Ozgur Yasar Akbal⁵, Mr, MD, oakbal@yahoo.com

INTRODUCTION: Heart rate variability (HRV) is widely used as a parameter to evaluate the autonomic status of the cardiovascular system. Autonomic nervous system shows increased sympathetic activity in patients with panic disorder.

METHOD: This study was designed to evaluate the autonomic activity in panic disorder by the comparison of 24 hour HRV analysis of new diagnosed panic disorder patients and 14 healthy age- gender matched control with holter electrocardiogram. Previous and new cardiovascular disease and usage of medications were absent in both groups. Blood counts, electrolytes, thyroid function tests were also normal. SDNN, SDANN, PNN50 and triangular index were determined from 24 hour holter analysis as HRV parameters.

RESULTS: There was no difference between the HRV parameters of panic disorder patients and healthy controls.

CONCLUSION: These results may be explained by the small sample size or the absence of cardiovascular effects in the periods without attacks of panic. However in the 24 hours holter periods none of the patients had an attack. Also HRV parameters may not be affected from panic disorder as previously reported in the literature. The patients who were new diagnosed to be have panic disorder began at least six months ago and absence of any psychotropic medication usage strengthens the hypothesis which insists that HRV parameters aren't affected by the panic disorder.

ASSOCIATION OF HYPOTHYROIDISM AND MANIA

INSTITUTIONS
1. University of Mississippi Medical Center, Psychiatry and Human Behavior, Jackson, Mississippi, United States

AUTHORS
1. Deepak Khemka¹, Dr, MD, dkhemka@psychiatry.umsmed.edu
2. Jeffrey Ali¹, Dr, MD, jali@psychiatry.umsmed.edu

In the differential diagnosis of mood disorders thyroid abnormalities rank high on the list of medical conditions to be ruled out in clinical practice. The classic associations are bipolar disorder with hyperthyroidism and depression with hypothyroidism. Recently we encountered two patients who presented with mania in the presence of persisting hypothyroidism. This prompted us to conduct a literature review using Pub Med and Medline on a possible association. Nine reports were identified in the period from 1980 -2007. Analyses of these show the following associations: 1) Mania and hypothyroidism were reported mostly in females; there is only one case report of a male with hypothyroidism and co-occurring mania; 2) Rapid cycling and hypothyroidism were reported more in females (consistent with established data); 3) Treatment generally involved using thyroid replacement (usually Levothyroxine). No specific mechanism(s) underlying the association of thyroid dysfunction and bipolar disorder were clearly identified. In addition, no data is available on ethnic and cultural variation. Further investigations to better understand this association both from an etiological and therapeutic perspectives are needed.

Anxiety and depression are common in people with Parkinson disease (PD) and cerebrovascular disorders (CVD). The aim of the present study was to assess anxiolytic efficacy and safety of tenoten (ultra-low doses of antibodies to s100 protein) in patients with PD and CVD. In a double-blind randomized placebo-controlled 4-week study patients with PD (G20) and CVD (I67.2, I67.4, I69.3) were randomized to receive either tenoten (10 tablets/day, n=32) or placebo (n=30) for 28 days. Anxiety was assessed at a baseline, day 28 and 28 days after discontinuation of the treatment. Primary endpoints were total Hamilton Anxiety scale score (HAMA-A) and response rate (≥ 50% reduction in HAM-A). The study demonstrated good clinical efficacy and safety of tenoten. In patients with PD tenoten reduced HAMA-A from 26.38±0.82 to 16.4±1.21 (vs from 27.13±0.65 to 26.07±1.05 in placebo group, p<0.05), in patients with CVD - from 28.19±1.01 to 13.19±0.7 (vs from 25.6±0.9 to 19.6±1.41 in placebo group, p<0.05), the number of responders was 20% and 62.5%, respectively (vs 0% and 6.7% in placebo group, respectively, p<0.05). Anxiolytic effect of tenoten was sustained after discontinuation of the treatment: HAMA-A was 15±1.01 in PD patients and 13.31±0.9 in CVD patients on day 56. There were no serious adverse events and no worsening of underlying neurological disorders in both groups. Tenoten is a drug of choice in the treatment of anxiety in neurologic patients.

4. Jong Doo Lee2, Dr., M.D., jdlee@yumc.yonsei.ac.kr

Anxiety is an important source of somatic symptoms in anxiety disorders and somatoform disorders. Functional brain-imaging studies have been critical for advancing our understanding of the neural circuitry of anxiety disorders. The purpose of this study is to compare regional brain function in patients with panic disorder and patients with undifferentiated somatoform disorder in order to determine if there is a common pathway in the neural circuitry underlying both disorders. Regional cerebral perfusion was measured by 99m-Tc-ECD (ethyl cysteinate dimer) Single Photon Emission Computed Tomography in the resting state. Using statistical parametric mapping (SPM) analysis, the SPECT images were compared on a voxel by voxel basis between 16 non-medicated, sex and age-matched patients with panic disorder and 10 healthy subjects and between 16 non-medicated, sex and age-matched patients with undifferentiated somatoform disorder and 10 healthy subjects. Cerebral perfusion in the right parahippocampal gyrus and right medial frontal gyrus was significantly reduced in each of the panic disorder and undifferentiated somatoform disorder groups compared to healthy controls (p<0.001). Cerebral perfusion was significantly increased in the left superior temporal, left inferior parietal, right superior frontal, and right middle frontal lobes in each of the two disorder groups compared to healthy controls (p<0.001). These findings suggest that the nondominant parahippocampal gyrus and medial frontal gyrus are involved in the pathophysiology of panic disorder and undifferentiated somatoform disorder and that the two disorders are likely to have a common pathway in the underlying neural circuitry.

5. Dasa Poredos1, Dr

Objectives: Purpose of the study was to gather information that would serve as basis for discussion on correlation between hopelessness and suicidality in war veterans. Hopelessness is a psychological construct that has been observed to underlie a variety of mental health disorders.

Material and Methods: The authors examined 300 subjects from group war veterans. The questionnaire “The Beck Hopelessness Scale (BHS)” was used in the survey (BHS; Beck, Weissman, Lester & Trexler, 1974). The BHS is a 20-item scale for measuring the extent of negative attitudes about the future (pessimism).

Conclusions: The study is a part of a wider project that deals with prevention of suicide.

7. Eleftheria Tsaltas, Dr, PhD, tsaltasl@med.uoa.gr

Rationale: We have proposed rewarded T-maze alternation as a model of obsessive compulsive disorder (OCD): the serotonin agonist m-chlorophenylpiperazine (mCPP) increments persistence the-rein, while chronic pretreatment with selective serotonin reuptake inhibitor (SSRI-fluoxetine) but not benzodiazepine or desipramine abolishes mCPP effects. However, we noted that acute SSRI admini-stration also causes transient persistence increase, counteracted by mCPP pretreatment.

Objectives: This study (a) further explores the cross-tolerance between fluoxetine and mCPP and (b) extends the model by investigating its sensitivity to dopaminergic manipulations (D2,3 agonism - quinpirole).

Methods: In both experiments, baseline and drug testing was carried out under daily T-maze alternation training. Exp.1 Matched group (n=8) pairs of rats received one of the following 20-day pretreatments (daily intraperitoneal administration): (1) saline, (2) low-dose fluoxetine (2.5mg/kg), (3) low-dose mCPP (0.5mg/kg) or (4) combined fluoxetine+mCPP. One group per pretreatment then received a 4-day challenge with high-dose fluoxetine (10mg/kg), the other with high-dose mCPP (2.5mg/kg). Exp.2: One group (n=12) of rats received 20-day treatment with saline, another with quinpi-role (0.5mg/kg).

Results: Exp.1: Saline and low-dose mCPP- or fluoxetine-pretreated animals showed significant persistence increases under both challenges, while combined low-dose fluoxetine+mCPP pretreatment afforded full protection from either challenge. Exp.2: Quinpirole significantly increased directional persistence after 13 administration days.

Conclusions: These results establish the sensitivity of the rewarded alternation OCD model to D2,3 receptor activation, thereby extending its profile of pharmacological isomorphism with OCD. Furthermore, they suggest a common mechanism of action of an SSRI and a serotonin agonist in the control of directional persistence.

8. Vladimir Krajca, Ing., CSc, 9. Cyril Hoschl, MD, DrSc., FRCPsyC

Objectives: Three small-scale studies have shown that a decrease of theta prefrontal EEG cordance after 1 week on antidepressant medication can predict clinical response to treatment. To obtain information about basic predictive characteristics of prefrontal EEG cordance decrease, we pooled data from published and unpublished studies.

Methods: We used a categorization of decrease to predict response and non-decrease to predict non-response. There was the total of 107 patients. Thirty-seven outpatients were treated in the USA and 70 inpatients were treated in the Czech Republic. Eighty-two out of the 107 patients did not respond to a minimal 1 antidepressant trial. Eighty-seven patients were treated with antidepressants and 20 with rTMS monotherapy.

Results: In 40 out of the 47 responders, a decrease of prefrontal cor-
dance was detected. There was no decrease of prefrontal cordance in 43 patients out of 60 non-responders.Computed sensitivity of prefrontal cordance decrease was 0.851, (95% confidence interval [CI] 0.720-0.929), specificity was 0.716; (95% CI 0.591-0.815), positive predictive value was 0.781; (95% CI 0.572-0.805) and negative predictive value was 0.860; (95% CI 0.735-0.933). The Number Need To Diagnosis (NND) was 1.76; (95% CI 1.45-2.52). Conclusion: Pooled analysis results support preliminary findings showing that QEEG cordance might be a useful test in early prediction of antidepressive response. The EEG cordance test are at least comparable to results of exercise ECG for coronary ischaemia. The prospective intervention study is needed to evaluate real cost and benefit in daily clinical practice. Supported by the grant MZCR NR9330

Nowadays, an application of neurosurgical methods in treatment of resistant anxious-obsessive disorders and depression is a usual practice. Many critical remarks have been leveled after analysis of using modern high technologies like stereotactic neurosurgery, deep brain stimulation (DBS) with vagus nerve stimulation and also modern methods of functional neuroimaging. DBS has solved a problem of neural destruction, and functional neuroimaging has given an explanation of resistance and pathogenically proved selecting of target structures. However, in a number of works there are facts, which are showing obvious contradictions. So, it is strange why both cingulotomy and stimulation of this limbic area can cause identical effect. On the basis of long-term supervision we have developed a clinical-pathogenetic approach to the selection of target structures. Thus, generalization of own experience and data of current literature about optimization of the neurosurgical approach to resistance overcoming in treatment malignant anxious-obsessive disorders was the purpose of this work. Data on surgical treatment of 32 patients with Obsessive-Compulsive Disorder and Tourette’s syndrome are presented. We also have analyzed data about a pathogenetic substantiation of resistance in anxious-obsessive disorder with the account of PET, MRI and MRS matrials. Data have revealed, that the decreased activity of caudate nucleus head neurons can be one of pathogenetic reasons of obsessive-compulsive disorder. The further operations were directed on stimulation of caudate nucleus and vagus nerve. The results allowed to assume that in each concrete case different approaches are expedient: as destructive operations on overactive brain structures, which are taking part in pathogenesis of anxiety and obsessions, so and complex operations for long-term neurostimulation of brain structures with decreased activity.

Objectives: (1) To assess the effects of vagus nerve stimulation (VNS) on regional cerebral blood flow (rCBF) in depressed patients and (2) to identify patterns of rCBF predictive of antidepressant response.

Methods: rCBF was assessed by HMPAO SPECT before and after 10 weeks of VNS in patients participating in a European open label multicenter trial (D03 study) investigating efficacy and safety of VNS. Patients suffered from major depression, (≥20 on the 24-item Hamilton Depression Rating Scale (HDRS)) and had been unsuccessfully treated with at least 2 adequately prescribed antidepressant drugs. Data of 15 patients were analysed using SPM 2000.

Results: After 10 weeks of VNS (20 Hz, 500 μs pulse width, stimulation during 30 seconds every 5 minutes at the maximal comfortable level) rCBF was increased in the left dorsolateral prefrontal cortex (DLPFC) and decreased in the right cuneus, precuneus and the left insula. Responders (N=4) had an increase of rCBF in the right posterior cingulate, putamen, left claustrum, fusiform and lingual gyri and a decrease in the right inferior parietal lobule, superior temporal and inferior frontal gyri and in the left claustrum compared to non-responders. Response after 1 year of VNS (N=9) was associated with increased rCBF at baseline in the right lingual, the left inferior temporal, the inferior and middle occipital gyri, in the cuneus and with decreases in the right middle frontal and left superior temporal gyri.

Conclusion: VNS as an antidepressant treatment increases rCBF in the left DLPFC. Other results have to be considered as preliminary.

5. Lana Marija Ilankovic⁴
6. Nemanja Lakovic⁵
7. Jelena Lacmanovic⁶, MD

Objectives: Prospective analysis of group of patients treated in Primary Health Care Center “Savski venac”, department of neuropsychiatry in Belgrade, Serbia. Thru the time period of 7 years we analyzed reactions connected with exposing to stress events which are consequence of democratic changes in Serbia in 2000, especially worsening of symptoms of depression until 2007 in patients with no history of mental illness.

Methods: Research included 100 patients from Belgrade, Serbia, average age group of 50 years and approximate equal number of male and female sex. They are divided in two groups in dependence of level of education. For examination we used: (1) original question mark - questions about reactions which frequently have people exposed to very stressful events, and (2) Hamilton Depressive Scale.

Results: (1) In both groups during the time we have occurrence of depression, anxiety, raise of irritability, impulsivity, appearance of aggressiveness, suicidal tendencies, abuse of psychoactive products and alcohol with disorder of interpersonal relationships, disappointment in institutions of state and society; (2) in 2007 are discovered significant increase of depressive score (HAMD) at 45% of tested patients without significant distinction between groups.

Conclusion: Stress events (stressful living) as consequence of changes in society, especially changes of old habits thru the years and new aspect of lifestyle is the reason of appearance and worsening symptoms of depression thru the time period of 7 years.

PERSONALITY DISORDERS AND TREATMENT OUTCOME OF PANIC DISORDER/AGORAPHOBIA

INSTITUTIONS
1. Institute of Psychiatry and Belgrade University, Belgrade, Serbia and Montenegro
2. Nepean Hospital and University of Sydney, Sydney, Australia

AUTHORS
1. Milan Lataš¹, Dr, PhD, latašm@eunet.yu
2. Vladan Starcevic², Dr, PhD

BACKGROUND: Several studies show that personality disorders are possibly the most robust predictors of nonresponse of pharmacological treatment of patients with panic disorder and agoraphobia.

OBJECTIVE: To ascertain influence of comorbid personality disorders diagnoses on the integrative therapy of patients with panic disorder and agoraphobia in the naturalistic setting.

METHOD: 119 outpatients with panic disorder and agoraphobia were treated by combination of cognitive-behavior therapy and pharmacotherapy (high-potency benzodiazepines + SSRI-es). Personality disorders diagnoses were estimated by the SCID II. Symptom severity was estimated before and after the end of treatment by clinician-administered instrument: Panic and Agoraphobia Scale (PAS), which consists of five dimensions related to symptoms of the disorder. Patients with and without personality disorders were compared by MANOVA and ANOVA with repeated measures.

RESULTS: At the beginning of treatment 57 (48%) patients with personality disorders exhibited more severe symptoms than patients without personality disorders on all PAS dimensions (p<0.001). All patients improved significantly. Patients with personality disorders improved significantly more than patients without personality disorders on all PAS dimensions (<0.05). However, at the end of the treatment patients with personality disorders exhibited more severe symptoms on dimensions that were related to panic attacks, impairment and hypochondria (p<0.05) but not to agoraphobia and anticipatory anxiety (p>0.05).

CONCLUSIONS: 1. Patients with panic disorder and agoraphobia with comorbid personality disorders had exhibited greater symptom severity and poorer response to integrative treatment vs. patients without personality disorders; 2. Comorbid personality disorders diagnosis adversely affect on integrative treatment outcome of panic disorder and agoraphobia.

4. Fung-Chang Sung, Dr., PhD, fcsung@mail.cmu.edu.tw

Aims / Objectives - To investigate the influence of parental death(s) on the subsequent risk of completed suicide in Taiwanese adolescents.

Methods - A total of 311 adolescents died of suicide at age 15-19 between 1997 and 2003 were identified from the death registry. For each case, 10 controls of the same birth cohort as the case and alive on the date when a case died were randomly selected from the birth registry. Study subjects’ birth characteristics, familial socioeconomic status, and parental personal identification numbers (PINs) were identified from the birth registry. Possible parental death(s) were identified through linking parental PINs to the death registry. Multivariate conditional logistic regression models were used in the analyses.

Results - After adjusting for birth characteristics and familial socioeconomic status, parental death(s) were observed to significantly increase the risk of adolescent suicide (adjusted odds ratio (AOR)=1.6, 95% CI 1.1-2.4). Additionally, a greater risk was found to be associated with parental death(s) from suicide (AOR=4.1, 95% CI 1.2-14.3) than with the death(s) from other causes (AOR=1.4, 95% CI 0.9-2.2). Moreover, a significantly and substantially increased risk was associated with paternal death from suicide (AOR=4.7, 95% CI 1.1-20.8), but not with mother’s suicidal death (AOR=3.3, 95% CI 0.3-32.8).

Conclusion - Parental death(s) especially paternal death from suicide may pose enormous influences on completed suicide in adolescents. This observation was independent of birth characteristics and familial socioeconomic status. Such findings may suggest the important roles of genetic factors or behavior mimicry in the causation of adolescents’ suicidal deaths.

Objectives - To compare the validity of the Patient Health Questionnaire (PHQ-9), Thai version and the five-item Mental Health Index (MHI-5) of the 36-item Short Form health survey (SF-36), Thai version as a screening tool for major depression in primary care patients in Thailand.

Methods - Three hundred patients in family practice clinic completed the PHQ-9 and the MHI-5. They were further assessed by the Mini International Neuropsychiatric Interview (MINI) as a gold-standard of diagnosis. Criterion validity and Receiver Operating Characteristics (ROC) were determined. Areas under the curves (AUCs) were compared statistically.

Results - The Cronbach alpha coefficients for the PHQ-9 and the MHI-5 were 0.79 and 0.81, respectively. For detecting major depression, the optimal cut-off for the PHQ-9 was 9 or greater (sensitivity 0.84, specificity 0.77, positive predictive value (PPV) of 0.21, negative predictive value (NPP) of 0.99, and the positive likelihood ratio of 3.71). The optimal cut-off for the MHI-5 total score was 61 or greater (sensitivity 0.95, specificity 0.80, positive predictive value (PPV) of 0.26, negative predictive value (NPP) of 0.99, and the positive likelihood ratio of 4.38). The area under the curve (AUC) was 0.89 (SE=0.05, 95% CI 0.85 to 0.92) for the PHQ-9 and 0.93 (SE=0.02, 95% CI 0.89 to 0.96) for the MHI-5. There was no significant difference between the AUCs for the PHQ-9 and the MHI-5 (p=0.35).

Conclusions - Both the PHQ-9 and the MHI-5 performed well in screening for major depression in general practice. The advantage of the MHI-5 was its brevity and simplicity of administration.

4. Dusica Lecic Tosevski

The relationship between depression and personality dimensions was explored in patients suffering from major depressive disorders (MDD).

Methods: The sample consisted of 60 patients with MDD diagnosed with ICD-X. The subjects were assessed by the 17-item Hamilton Rating Scale for Depression and MCMI III questionnaire.

Results: High prevalence of avoidant, passive aggressive, depressive, dependent and antisocial dimensions was found. There were no significant differences between genders except of a higher prevalence of shizotipal personality dimension in males. Histrionic, narcissistic and compulsive personality dimensions were low in our sample of patients with MDD.

Conclusions: Assessing particularly personality dimensions can predict severity and duration of depression. In addition to that appropriate pharmacotherapy and psychotherapy can be planned and individualized.

4. Dan J. Stein
5. Michael Van Ameringen
6. Francine Mandel

Aim/Objective: This retrospective analysis evaluated the effects of treatment with pregabalin (PGB) on two common clinical subgroups of GAD: patients presenting with prominent gastrointestinal (GI) symptoms and those with high levels of insomnia.

Methods: Data were pooled from six double-blind, placebo-controlled (PBO), 4-6 week trials of outpatients (N=1555) with DSM-IV GAD. PGB response was analyzed for three fixed-dosage groups, 150mg/d, 300-450mg/d, and 600mg/d. A high insomnia subgroup was defined by a baseline 3-item HAM-D insomnia factor score ≥4 (max score=6). A high-GI symptom subgroup included patients with a baseline HAM-A item-11 (GI) score ≥3 (severe/very severe).

Results: At baseline, 31% of the total sample was in the high-insomnia subgroup, and 17% was in the high-GI subgroup. For the high-insomnia subgroup, treatment with PGB resulted in significantly greater improvement in HAM-A total score at LOCF-endpoint for PGB-150 mg (-10.3±1.01), PGB-300/450 mg (-12.4±0.88), PGB-600 mg (-11.6±0.72) vs. PBO (-8.4±0.66; all comparisons: P<0.0001). In the high-insomnia subgroup, significantly more patients were insomnia responders (reduction to minimal-to-no levels of insomnia) on combined doses of PGB vs PBO (P<0.005). For the high-GI subgroup, LOCF-endpoint reduction in HAM-A was significantly higher on PGB-150 mg (-13.8±1.7), PGB-300/450 mg (-13.5±1.2), and PGB-600 mg (-14.8±1.1), compared to PBO (-10.6±1.0; P<0.0001 for all comparisons). In the GI-high subgroup, the proportion of patients showing a response in GI symptoms was significantly higher on combined doses of PGB vs PBO (P<0.0001).

Conclusion: Pregabalin was an effective treatment in GAD patients presenting with high levels of insomnia and GI symptoms.

Aims: To examine therapeutic efficacy of venlafaxine in reduction of depressive symptoms, anxiety and psychomotor poverty in patients with severe depressive episode as well as its tolerability and safety in combined treatment with mood stabilizers and atypical antipsychotics.

Methods: In the study were included 40 outpatients followed-up for 8 weeks with clinical scales (HDRS and CGI) at check points at 7, 14, 21, 28, 42 and 56 days and laboratory test at the beginning and the end of the study. Statistics with Friedman and Wilcoxon tests.

Results: HDRS score at the beginning of treatment was 29.1 and after two weeks 20.2. Although signs of reduction of depressive symptomatology are observed early in the treatment, reduction of 50% and more is achieved at 28 day of treatment with HDRS score 12.9. Scores below 8 points on HDRS are achieved at 56 days of treatment.

Conclusions: Venlafaxine is antidepressant with good and proven efficacy but we need to be patient and wait for the expected results. The drug is well tolerated in combined treatment at optimal doses.

Aim: To compare different parameters of efficacy, between sublingual (ALP-SL) and conventional (ALP-CT) tablets of alprazolam in the treatment of acute phase of panic disorder with and without agoraphobia.

Methods: Comparative, multicenter (6 research sites), double-blind, randomized, fixed-flexible dose study. 190 outpatients with panic disorder with (n=117) and without (n=73) agoraphobia (DSM-IV diagnostic criteria), 36% with psychiatric comorbidity, were treated with ALP-SL or ALP-CT for 12 weeks. Outcome was assessed with: Clinical Global Impressions (CGI-S/CGI-I), Hamilton Rating Scale for Anxiety (HAM-A), Arizona Sexual Experiences Scale (ASEX), Patient Global Impression (PGI), Psychological General Well-Being Index (PGWBI), Panic Disorder Severity Scale (PDSS), also by the number of panic attacks and extension and intensity of panic attacks and anticipatory anxiety.

Results: Pharmacological treatment resulted in a clinically and statistically significant improvement in all severity measures. ASEX presented no changes during the study. The average dose of alprazolam for 12 weeks was 1.36 ± 0.70 mg/day (1.39 ± 0.77 ALP-CT and 1.33 ± 0.64 ALP-SL). With ALP-SL panic attacks were shorter (p<0.05) as well as the extension (p=0.16), intensity of anticipatory anxiety (p=0.14). Treatment were well tolerated presenting no differences between both groups.

Conclusion: Alprazolam proved efficacy, safety and good tolerability in the treatment of the acute phase of panic disorder. ALP-SL showed some comparative advantages.

3. Aleksandar Miljatovic¹, Dr.

OBJECTIVE: Depression is a frequent disorder at patients in phase of terminal uremia which are on a permanent program of hemodialysis. The aim of the work is assessment of frequency and level of depression at patients which are on a permanent program of hemodialysis.

METHODS: 30 patients were divided into two equal groups of 15. in the first group were observed patients that are on a hemodialysis program up to 5 years, while in the second group were observed patients that are on a hemodialysis program for more than 5 years. Instruments used in order to measure depression were: HAMD and MADRS scales.

RESULTS: In both groups results measured on scales HAMD and MADRS showed that patients belonged in the group of depressive ones. Results that implied on depression were collected within each group of patients, no matter of the duration of hemodialysis program. On the basis of collected results, there is a noticeable fact that does not exist a significant difference in intensity of depression between these two groups of patients.

CONCLUSION: Frequency and intensity of depression at patients which are on hemodialysis program is similar, no matter of duration of hemodialysis program.

PECULIARITIES OF PERSONALITY IN PATIENTS WITH DYSTHYMIA

INSTITUTIONS
1. "Institute of Neurology, Psychiatry and Narcology of the AMS of Ukraine" SI, Dpt. of Neuroses and Borderline Disorders, Kharkiv, Ukraine

AUTHORS
1. Natalia O. Maruta¹, Prof., MD, PhD, akutikov@ukr.net
2. Yurii M. Zavalko¹, Dr., MD, akutikov@ukr.net

The aim of this investigation was to research peculiarities of personality in patients with dysthymia. A complex of methods included a clinical-psychopathological examination, psychodiagnostic methods (R. Cattell's test, W. Spilberger’s and Yu. Khanin’s Scale, Sachs and Lewy's test of uncomplete sentences) and method of mathematical statistics. 182 patients with dysthymia (F 34.1) of the age from 20 to 49 years old were examined, including 39.5% of male patients and 60.5% of female ones. Results of the investigations demonstrated that the main predictors of dysthymia formation were a constitutional trend to depressive conditions, a conflict combination of peculiarities of the personality, and a mechanism of exaggeration of severeness of present depressive disorders. A conflict combination of peculiarities of the personality in patients with dysthymia is manifested on the one hand by independence of character, trend to dominate, and an autonomy in a social behavior, and on the other hand by a low self-estimation, a high level of anxiety, diffidence, problems in formation of social contacts and in making of decisions. The mechanism of psychological exaggeration of severeness of present depressive disorders contributed to fasten depressive forms of reactivity in the patient's behavior and to increasing of severeness of the disease. The described above combination of psychological features results in a low stress-rigidity, a chronical frustration, emotional tension, and psychosomatic disadaptation. It is necessary to take into account this fact in the psychotherapeutic treatment.

Gastroesophageal symptoms are common in both primary and specialist practice even in psychiatric outpatient clinics. Psychological factors in functional dyspepsia have been discussed by many investigators. However, there has been little systematic research to investigate about relationship between gastroesophageal symptoms and depressive symptoms. We investigated these relationships using a frequency scale for the symptoms of gastroesophageal reflux disease (FSSG) and the Center for Epidemiologic Study Depression Scale (CES-D). The FSSG consists of 12 items for the symptoms of gastroesophageal reflux disease. The CES-D is 20 items scale consisting of four factors. The samples were recruited in the department of Psychiatry of Tokyo Medical University Hospital from September, 2005 to January, 2007. In this presentation, we will report distribution of gastoroesophageal symptoms on each diagnosis and the relationships between each items of the FSSG and the CES-D.

Introduction: Sertraline is SSRI antidepressant commonly used in Macedonia in the treatment of depressive patients. Our study was in order to determine the optimal dose and suitable duration of Sertraline in the treatment of depression.

Methods: In our retrospective study we treated 112 depressed outpatients at the Clinic of Psychiatry during 3 month period, 2007. The comparison during the study was between the dose response and the initial clinical action of Sertraline.

Results: Our results improved that big daily doses (100mg) Sertraline were more effective than lower doses (50-75mg). The percentage of improved patients was more than 75% in six week period.

Conclusion: Sertraline is effective antidepressant in the treatment of depression in a recommended daily dose of 100mg. If improvement has not been seen within five weeks the daily doses should be increased in a next 4 week period. After this period Sertraline should be altered.

5. Anna Rys¹

Aim: The aim of this work is to present a conception of β1-endorphin depression disorders with various etiology.

Approach: In the middle of 70-ties opioid peptides were found and it was noticed, that they play an important role in homeostasis regulation, having a part in numerous physiological functions. The most recognized and playing especially important role in those processes opioid peptide is β-endorphine especially, play a role in pathophysiology of mood disorder.

Conclusions: β1-endorphin is an important link in homeostasis regulation because it influences higher nerve functions, such as learning processes and memory, mood and drive. There are many researches showing lower level of β1-endorphin at patients with depression disorders compared to the control group. They show also, that β1-endorphin level at patients with endogenous depression disorders is lower than in exogenous depression disorders.

Aims: We examined the relationship between psychiatric diagnoses and suicide methods in Japanese suicide attempters.

Methods: Subjects were 281 suicide attempters who were treated at the Kitasato University Hospital, Emergency Department between January 2006 and December 2007. The information about the attempters regarding demographics, suicide method, clinical characteristics, and ICD-10 diagnosis were collected by means of the medical records and used for analyses.

Results: Two hundred and thirty one subjects (82.2%, 82 male, 149 female; 37.3±15.4 years old) met the diagnostic criteria for ICD-10, of which 111 (48.1%) were F3, 52 (22.5%) were F2, 33 (14.3%) were F6, 21 (9.1%) were F4, and 14 (6.1%) were other categories. The one-way analysis of variance revealed the significant differences between the psychiatric diagnoses in the age of subjects (F (3,213) = 3.4, p=.02). Post hoc comparison revealed that those with F6 were significantly younger than those with other disorders. The chi-square test showed that drug over dose was the most frequent suicide method in F3 and F6, jumping from high place was in F2, and laceration was in F4 (X²= 40.8, df= 27, p=.04). Also, the chi-square test revealed the significant differences for psychiatric diagnoses in previous psychiatric treatment, previous psychiatric hospitalization, occupation, and marital status.

Conclusion: Our study showed clinically significant relationship between psychiatric diagnoses and suicide methods. It is suggested that providing an appropriate treatment based on an accurate psychiatric diagnosis at the emergency department might benefit from suicide prevention.

2. Andrzej Bembenek², Dr., MD
3. Andrzej Polewka³, Dr., MD
4. Włodzimierz Brodniak⁴, Dr., MD

Aims: Suicide is one of the public health concerns in Poland. Almost 5000 deaths annually are reported. Providing the fact that there is lack of studies on the seasonality of suicide in the Polish population, the present study aims at the estimation of the seasonality of suicides in the country.

Method: We analysed 29,232 suicidal deaths in Poland by age and gender. Data concerning suicidal deaths in Poland were collected by the Central Statistical Office using the statistical part of death certificates. The cases of suicides are coded according to the International Classification ICD-10. In the analyses, the Demetra v. 2.04 statistical program devised by the European Statistical Office (Eurostat) was used. The X-12-ARIMA method was selected for statistical analysis purposes.

Results: The mean suicide rate in Poland in the years 1999-2003 was 15.23 per 100,000 population. The rate for men was 26.47, whereas for women it was only 4.64. Stable seasonality of suicides was confirmed only for the following three models that satisfied requirements of all diagnostic tests: for the total of suicides committed in Poland, for all suicides committed by individuals aged 40-44, for men in the age range 40-44.

Conclusion: We found a stable seasonality of suicide with a spring-summer peak and a winter trough, observed for the total population of suicides and males between 40 and 44 years of age. As in other countries, the results of our research may be of considerable import for the development of effective suicide prevention strategies.

REFRACTORY OBSESSIVE-COMPULSIVE DISORDER - CASE REPORT AND REVIEW OF 40 YEARS OF LITERATURE

INSTITUTIONS
1. Universidade Federal do Paraná (UFPR), PSYCHIATRY, CURITIBA, Brazil
2. Universidade Federal do Paraná, PSYQUIATRY, CURITIBA, Brazil

AUTHORS
1. Sonia Zimmer Moitim¹, Dr, MD, remmiz@terra.com.br
2. Salmo Zugman², Dr., MD, salmoz@terra.com.br

OBJECTIVE: The authors retrospectively reviewed the treatment options, as surgical procedures employed in the treatment of obsessive-compulsive disorder (OCD) refractory and/or resistance in the last 40 years.

METHOD: They were searched articles published between the years of 1966 and October of 2007 with the keywords: REFRACTORY and OBSESSIVE and DISORDER and TREATMENT and RESISTANT through MEDLINE, LILACS, Cochrane Library and SCIELO addition to active search manual found in the references. Among 147 were 64 articles on the specific issue, including studies open, double-blind and a case report, to 21/10/2007 to 8:00 pm. These articles refer to the treatment of patients "non-responders" alone before increase suggested in each article illustrated in the selection. Moreover, the authors have taken care to minimize the strategies, in order to emphasize the theme, excluding items related to gestational period, puerperal and child, those addressing tiques and tourette and trastornos associated with panic, bipolar, schizophrenia and/or primary or anxiety.

CONCLUSION: A polymorphism and the severity with which the disorder presents itself allow therapeutic options considered among risperidone and ISRS. It has complained about potential with benzodiazepine (clonazepam) during case related. Negative results were found between therapeutic use. The evidence suggests that the addition of low-dose dopamine antagonists seem to be a viable option as a strategy in the treatment of obsessive-compulsive disorder refractory. The diagnostic impression of the psychiatrist is important for better clinical correlation. This and other similar cases corroborate with the current literature, but if controlled studies are needed.

7. Alexandra Whitworth⁵, Dr, MD
8. Christoph Stuppaeck⁶, Dr, MD

Objective: The Young Mania Rating Scale (YMRS) is the most widely used assessment tool for severity of manic symptoms in bipolar patients. While the original English version has been translated to various different languages, a German translation and validation of YMRS is not yet available.

Methods: We translated the original English version to German (YMRS-G) and tested its use in clinical practice in 81 manic patients at two different psychiatric hospitals in Austria. The interviews were carried out by eight experienced and trained psychiatrists in random pairs of two interviewers.

Results: Inter-rater reliability was assessed calculating the Intraclass Correlation Coefficient and showed high values (between 0.82 and 0.94, p<.001) in all items of the German Rating Scale. In order to assess validity of YMRS-G, all patients were simultaneously rated using the Clinical Global Impression Rating Scale, Bipolar Version (CGI-BP), by one of three experienced senior raters. Spearman’s rank correlation coefficient for the total scores of CGI-BP and YMRS-G was high (0.91, p<0.001), suggesting good validity of YMRS-G.

Conclusion: In conclusion, the German version of YMRS seems to be a valid, reliable and useful tool for the assessment and quantification of manic symptoms.

EFFICACY OF PREGABALIN AND VENLAFAXINE-XR IN GENERALIZED ANXIETY DISORDER: RESULTS OF A DOUBLE-BLIND, PLACEBO-CONTROLLED 8-WEEK TRIAL

INSTITUTIONS
1. Pfizer Global Pharmaceuticals, Pfizer Inc, New York, New York, United States
2. Università di Sassari, Italy
3. Clinica Psichiatrica-Università di Catania, Italy

AUTHORS
1. T. Kevin Murphy¹
2. Giancarlo Nivoli²
3. Antonino Petralia³
4. Francine Mandel¹
4. Barry Herman¹

Aim/Objective: To evaluate the comparative speed of onset of anxiolytic activity, and the overall efficacy of pregabalin (PGB) and venlafaxine-XR (VXR) in patients with GAD.

Methods: Adult outpatients with DSM-IV GAD were randomized double-blind to 8-weeks flexible-dose PGB 300-600mg/d, VXR 75-225mg/d, or placebo (PBO). The primary outcome was endpoint change in HAM-A total score. Patients with major depression, or a baseline HAM-D >15, were excluded.

Results: 121 patients were randomized to PGB (baseline HAM-A, 27.6±0.4; baseline CGI-Severity, 4.74±0.7); 125 patients to VXR (baseline HAM-A, 27.4±0.4; CGI-S, 4.78±0.7); and 128 patients to PBO (baseline HAM-A, 26.8±0.4; CGI-S, 4.66±0.7). PGB was associated with a significantly greater LS-mean change in HAM-A total score at LOCF-endpoint vs PBO (-14.5±0.9 vs -11.7±0.9; P=0.028). VXR treatment was not significant vs PBO at endpoint (-12.0±0.9; -11.7±0.9; P=0.968). PGB treatment showed an early onset of improvement, with significantly greater LS-mean change in HAM-A by day 4 vs both PBO (-5.3±0.5 vs -3.4±0.5, P<0.008) and VXR (-2.9 ± 0.5; P=0.0012). Proportions of severe AEs were similar for PGB (9.1%) and PBO (7.8%), but higher for VXR (20.0%). Premature discontinuation due to AEs was higher on both PGB (12.4%) and VXR (17.6%) vs PBO (5.5%).

Conclusions: Pregabalin safely and effectively treated GAD, with a significantly earlier onset of anxiolytic activity than venlafaxine-XR. The magnitude of endpoint HAM-A improvement on venlafaxine-XR was comparable to that reported in previous trials. The failure of venlafaxine-XR to demonstrate significant efficacy versus placebo may be attributable to a relatively high placebo response in this study. Study funded by Pfizer Inc.
P-03-113
COMPARISON OF SLEEP OUTCOMES IN GENERALIZED ANXIETY DISORDER FOLLOWING TREATMENT WITH PREGABALIN OR VENLAFAXINE-XR

INSTITUTIONS
1. Pfizer Global Pharmaceuticals, Pfizer Inc, New York, New York, United States

AUTHORS
1. Marko Mychaskiw
2. Deborah L. Hoffman
3. Barry Herman

Objectives: To evaluate the differential impact of pregabalin and venlafaxine extended release (XR) versus placebo on sleep outcomes in non-depressed outpatients with generalized anxiety disorder (GAD).

Methods: A secondary analysis of data from an 8-week, double-blind, randomized, flexible-dose, placebo-controlled study in non-depressed GAD patients. Patients (N=374) received pregabalin (300-600mg/day), venlafaxine-XR (75-225mg/day) or placebo. Sleep was evaluated at baseline, weeks 4, 8, and endpoint using the Medical Outcomes Study (MOS) Sleep Scale (sleep disturbance, adequacy, quantity, optimum sleep, daytime somnolence, snoring, awakening short of breath/headache); 2 sleep-problem indices were also employed. Sleep quantity and optimal-sleep scales were based on the average number of hours slept/night within prior 4 weeks. Except for optimal sleep (yes/no), scores ranged from 0-100 (higher scores representing higher sleep-characteristic level). Outcomes (except optimal sleep) were compared between the 3 study-drug groups at weeks 4, 8, and endpoint using ANCOVA (covariates: investigator center, baseline scores); analysis based on observed cases, except for LOCF at endpoint.

Results: Significant differences favoring pregabalin versus placebo were observed at all time points on sleep-disturbance scales (P-value range, <0.0001 to 0.007) and the 2 sleep-problem indices (P-value range, 0.0001 to 0.01). Venlafaxine-XR did not differ from placebo.

Conclusions: Pregabalin-treated GAD patients displayed better sleep outcomes versus placebo, and did not report significant changes from baseline in daytime somnolence. Venlafaxine-XR-treated patients did not report better sleep outcomes versus placebo. Improvement of sleep disturbance, a common medical-help-seeking reason in GAD patients, may contribute to the reduction of its associated human and healthcare burden.

P-03-114
COST-EFFECTIVENESS OF PREGABALIN VERSUS VENLAFAXINE IN THE TREATMENT OF PATIENTS WITH GENERALIZED ANXIETY DISORDERS: A SPANISH PERSPECTIVE

INSTITUTIONS
1. Policy Analysis Inc. (PAI), Brookline, Massachusetts, United States
2. Pfizer Global Outcomes Research, New York, New York, United States
3. Pfizer España, Health Outcomes Research Department, Medical Unit, Alcobendas (Madrid), Spain

AUTHORS
1. Montserrat Vera-llonch
2. Ellen Dukes
3. Marko Mychaskiw
4. Oster Gerry
5. Javier Rejas

Aims/Objectives: To assess the cost-effectiveness of pregabalin in the treatment of patients with generalized anxiety disorders (GAD) from a Spanish perspective.

Methods: We developed an analytic model to estimate clinical and economic outcomes over 12 weeks for a hypothetical cohort of patients with GAD, alternatively treated with flexible dosages of pregabalin (300-600 mg/d) and venlafaxine XR (75-225 mg/d). Severity of GAD symptoms was characterized using pre-treatment Hamilton Anxiety Scale (HAM-A) scores from a randomized, placebo-controlled clinical trial. Model health states were characterized by HAM-A scores; moderate or severe anxiety was assumed to be defined by a HAM-A score >16. Expected changes in HAM-A scores (vs pre-treatment) were estimated using trial data. Health-state utilities were assigned to each patient based on expected HAM-A scores. Costs included those of medication and other direct medical and non-medical care services in Spain. Model outcomes included the expected mean HAM-A score with treatment, the expected number of weeks without moderate or severe anxiety, and quality-adjusted life expectancy. Cost-effectiveness was expressed as incremental cost per quality-adjusted life-year (QALY) gained.

Results: In comparison with venlafaxine, pregabalin treatment was estimated to yield a mean reduction of 2.2 in HAM-A scores over 12 weeks, 1.8 additional weeks without moderate or severe anxiety, and a gain of 0.0063 QALYs. The incremental cost (95% CI) of pregabalin therapy (vs venlafaxine) per QALY gained was €28,323 (€23,380, €33,954).

Conclusions: In patients with moderate or severe GAD in Spain, the cost-effectiveness of pregabalin (vs venlafaxine) falls within accepted published thresholds.

DIFFERENTIAL CORRELATION BETWEEN DIFFUSION TENSOR IMAGING FINDINGS AND FACTOR ANALYZED SYMPTOM DIMENSIONS IN OBSESSIVE-COMPULSIVE DISORDER

INSTITUTIONS
1. Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Department of Psychiatry, Kyoto, Japan

AUTHORS

Aim/Objectives
Obsessive-compulsive disorder (OCD) is clinically heterogeneous and it has been hypothesized that discrete neural systems might mediate the expression of different symptoms (1). The goal of this study is to investigate the neural correlates of each symptom dimensions in OCD by using diffusion tensor imaging (DTI).

Methods
Thirty one patients with OCD underwent DTI and were administered the Yale-Brown Obsessive-Compulsive Scale Symptom Checklist. Thirteen main symptom categories were factor analyzed by using principal components analysis. Voxelwise analysis was used to investigate the correlation between fractional anisotropy (FA) and each factor scores covarying for severity, age and sex. Pearson product-moment correlations were used and the statistical threshold was defined as a t statistic above 3.43 (p < 0.001, uncorrected) and contiguous voxels above 20.

Results
The factor analysis identified four factors that explained 69.0% of total variance and were named as follows: hoarding, contamination/cleaning, symmetry/ordering, aggressive/checking. Factor scores of symmetry/ordering were significantly negatively correlated with FA in right temporal lobe and left extra nuclear region. Factor scores of aggressive/checking were significantly positively correlated with FA in right middle frontal lobe. There was no significant correlation between factor scores of hoarding, contamination/cleaning and FA.

Conclusions
Discrete neural systems might mediate the expression of different OCD symptoms.

Aims/Objective: We aim to describe the psychopathological and clinical features of clonazepam withdrawal after a long term treatment for panic disorder.

Method: The protocol consisted of clonazepam dose decrease during 4 months and another 8 months of follow-up. The dose was decreased 0.5 mg per two-week period until it reaches 1 mg per day, then 0.25mg was taken out every week. The PD patients were taking clonazepam for at least three years of PD treatment. 73 patients who were asymptomatic of their PD for at least one-year and desired to leave the medication.

Results: 51 (68.9%) of the patients were free of the medication after the 4 months of tapering as the protocol. 19 (26.0%) needed another 3 months to leave the medication. 9 (12.3%) patients gave up the tapering due to return of anxiety. The mean dose at starting the tapering out was 2.7±1.2 mg/day. The withdrawal symptoms were mild and observed in 55 (75.3%) patients. No serious adverse events were observed. Insomnia, tremor, nausea, sweating, headache, and subjective anxiety were the main complaints. 40 (54.8%) patients were asymptomatic without any medication after the 8 months follow-up and 10 (13.7%) had returned to the use of benzodiazepine.

Conclusions: If the clonazepam dose is tapering slowly and some adjunct drug could be use in some few cases, it is possible to take the clonazepam slowly out even after a long treatment without any major withdrawal symptom.

also mirtazapine or carbamazepine as adjunct therapy. 3 (4.1%) patients gave up the tapering due to return of anxiety. The mean dose at staring the tapering out was 2.7±1.2 mg/day. The withdrawal symptoms were mild and observed in 55 (75.3%) patients. No serious adverse events were observed. Insomnia, tremor, nausea, sweating, headache, and subjective anxiety were the main complaints. 40 (54.8%) patients were asymptomatic without any medication after the 8 months follow-up and 10 (13.7%) had returned to the use of benzodiazepine.

Conclusions: If the clonazepam dose is tapering slowly and some adjunct drug could be use in some few cases, it is possible to take the clonazepam slowly out even after a long treatment without any major withdrawal symptom.

4. Veronika Hublova

Objectives: It is known that individuals with depression suffer from cognitive impairment across a broad spectrum of cognitive domains. Less is clear about factors, which may influence this status. In our study we investigated profile and dynamics of cognitive performance by patients with major depressive disorder. We tried to find, whether predicted factors (depressive symptomatology, response to treatment, current emotional state and personality characteristics) are related to cognitive performance.

Methods: 25 in-patients with MDD (ICD-10) were assessed with comprehensive neuropsychological test battery at the beginning and at the end of acute treatment. Interval was 28 days. Assessment of predicted factors was made simultaneously with use objective and subjective scales. Statistic methods were applied for obtaining results.

Results: We found cognitive impairment at the beginning of the treatment. Cognitive performance was partly improved after acute treatment, nevertheless certain aspects of cognitive impairment persisted. Cognitive performance was related to depressive symptomatology and response to treatment. Current emotional state had relation with attentional performance.

Conclusion: We investigated profile and dynamics of cognitive performance by patients with major depressive disorder and find some factors which are related to cognitive aspects of depression.

SUICIDE IN GRECO-ROMAN MYTHOLOGY CHARACTERS

INSTITUTIONS
1. Sobral Cid Psychiatric Hospital, Psychiatry, Coimbra, Portugal

AUTHORS
1. Carla SS Silva, Dr., MD, csofiass.carla@gmail.com
2. Maria AB Mateus, Dr., MD
3. Óscar SN Nogueiro, Dr., MD

The authors carry out a brief review on suicides consummated by mythology characters. This suicide behaviour occurs in diverse contexts and by distinct methods (drowning, hanging, by a cutting weapon, precipitation and immolation). Hercules, Narcissus, Jocasta and Fedra cases are between those that are cited.

Objectives: Physical expression of general stress is common all over the world. Somatization can be defined as somatic disorders which cannot be explained with physical symptoms. The rate of somatization disorders vary from one to another society and from west to east. Somatization is so common in the oriental cultures. However, there are very few studies on somatization disorders of young adults both in Turkey and other oriental countries. Thus, the purpose of this study was to find out the lifelong prevalence and related possible risk factors of somatization disorder at the young-adults.

Method: The number of the participants is 804 (508 females, 296 males), aged between 18 and 27 years. We first applied a semi-constructed questionnaire for sociodemographic characteristics and then GHQ-12 and CIDI part C for the psychiatric diagnosis. Logistic regression was used in order to determine related possible risk factors of somatization disorder.

Results: Somatization disorder was diagnosed at 62 person (7.7%). We obtained statistically significant results between feminine, chronic illness, the low educational level of mother, verbal abuse in the family and somatization disorder (OR= 2.762, p= 0.015; OR=0.260, p=0.020; OR= 4,301, p=0.030; OR= 4.507, p=0.022).

Conclusion: This results were showed that feminine, chronic illness, the low educational level of mother and verbal abuse in the family were important risk factors for the development of somatization disorders of the young-adults in our country. The health care professionals working with young adults should be aware of somatization disorder.

4. Oguz Kutlu⁴, Mr., PhD, okutlu@cu.edu.tr

Objective: The young person often move from their city both for graduation and to earn their living in Turkey. Especially thousands of young students change place for graduation every year and it is known that they have encounter many problems during university years in our country. There are only few studies that search the obsessive compulsive symptoms of the university students on the literature. In this study we aim to determine the lifelong prevalence and accompanying risk factors of the obsessive-compulsive disorder (OCD) at the students of an education faculty in Turkey.

Method: Total 804 Education Faculty students was included to study (508 females, 296 males), aged between 18 and 27 years. We first applied a semi-constructed questionnaire for sociodemographic characteristics and then GHQ-12 and CIDI part K for the psychiatric diagnosis. Logistic regression was used in order to determine related possible risk factors of OCD.

Results: OCD was diagnosed at 33 students (4.1%). We determined statistically significant results between female gender, having own room in their parents’ home, peration history, verbal harassment and OCD (OR=3,677, p=0.014; OR=3,198, p=0.020; OR=0,150, p=0.031; OR=17,286, p=0.001).

Conclusion: We found the incidence of OCD high in our study comparing to other epidemiological surveys. It is a pioneer study that indicates the psychological reflections of students graduating in an Education Faculty in Turkey. We believe that this study contribute to enlighten the morbidity of OCD in our region.

2. Seda Sahin
3. Sibel Cakir
4. Olcay Yazici

Objectives: Despite the effectiveness of several treatments in long-term prophylaxis of bipolar disorder, there is still a considerable amount of patient that do not respond. The aim of this study is to assess the effectiveness of prophylaxis with clozapine in treatment resistant bipolar patients.

Method: In this case report, the use of clozapine for prophylaxis is retrospectively assessed in 290 bipolar patients.

Results: 12 of 290 (%4.1) bipolar patients used clozapine for long-term prophylaxis. Three patients had four, another three patients had three and others had two non-responsive prophylaxis treatment before clozapine. In 11 of 12 patients, episodes were severe, predominant episode type was manic and they had psychotic symptoms at least one period. All the patients responded to long-term treatments that include clozapine.

Conclusion: Long-term prophylaxis treatments that include clozapine can be effective in resistant bipolar patients.

THE CLINICAL IMPACT OF SOCIAL ANXIETY DISORDER ON BIPOLAR DISORDER

INSTITUTIONS
1. Istanbul Medical School, Psychiatry Department, Istanbul, Turkey

AUTHORS
1. Ilker Ozyildirim
2. Olcay Yazici

Objectives: Social anxiety disorder (SAD) comorbidity in bipolar disorder (BD) is associated with high rates of suicidality and poorer overall outcome. In the present study, the aim was to assess the impact of SAD comorbidity on the clinical features, illness severity and response to mood stabilizers in bipolar patients.

Method: One hundred and sixty bipolar patients were assessed by means of the Structured Clinical Interview for DSM-IV axis-I (SCID-I) in order to detect all possible psychiatric comorbid diagnosis. The sample was split according to the presence of SAD comorbidity and the groups were compared.

Results: SAD comorbidity was detected in %17.5 (28/160) of the bipolar patients. SAD comorbid bipolar patients had early onset of BD and more severe episodes. There was not a difference between groups for total number of episodes, hospitalization, suicidality, being psychotic, treatment response to lithium and anticonvulsants.

Conclusion: SAD comorbidity may be associated with more severe episodes and early onset in BD. But SAD comorbidity may not be related to treatment response in bipolar patients.

It has been estimated that 25 to 30% of women will suffer a depressive disorder in their lifetime. This is 2 to 3 times greater than the lifetime prevalence for men. During perimenopausal period there is a higher risk of developing depression. We intend to analyze factors involved in the onset of depressive disorders in perimenopausal women. We performed a retrospective revision of the affective disorders among 40 to 60-year-old women in inwards between January 2003 to May 2007, studying percentage of women, gender distribution, diagnosis at release and time of stay. The total sample was compared to the group of perimenopause. Among the group of 40 to 60 year-old women with a diagnosis of affective disorder, variables that could have influence on this pathology were reviewed. From 212 women admitted during that period, 41.5% were diagnosed of affective disorders. 20.75% were 40 to 60 years old, which constitute the sample for our study. Variables observed were age, cause of psychiatric hospitalization, acute disease, medical and psychiatric background, family background, family life and average time of hospitalization. Among the group of 40 to 60 year-old women with affective disorders studied, 56% of them had previous episodes of depression. 40% of them had at least 3 medical or surgical pathologies. Deficit of folic acid or B12 vitamin was found in 20% of them, while 16% had protein deficit. 20% of them lived with on their own, although most of the other 80% had familiar or social problems.

Purpose: Knowing patients’ opinions about their feelings about depression. Materials and methods: The article presents results of studies on hospital patients suffering from intermittent depression. Authors would like to know the patients’ opinions about the changes made by mental disease in their life (family life, daily life, school, job). Thirty patients had to answer 23 questions, in a part of which answers were YES or NO but in the main patients had to write a few sentences about their impressions of their life situation and problems concerning emotions (happiness, fear, trust, love, friendship, loneliness), religion (faith, sins, suicide thoughts) and treatment. Results and conclusions: Half of the patients recognized themselves as ill people and all the aspects of their life got worst because of the mental disease.

Aims/Objectives: Bipolar Disorder has become an issue of special interest in recent years as a result of it being one of the psychiatric diseases with most complex treatment and hardest to standardize, manic episodes often requiring admittance to a hospital. Our objective is to describe the sociodemographical, health care and therapeutical aproachment in Bipolar Disorder.

Methods: We performed a descriptive study of a sample of 98 patients that had been admitted at least once at Psychiatry Unit, being diagnosed from Bipolar Disorder Type I most recent episode manic.

Results: The average age was 48.42 ±14.16 years old, each gender accounting for a 50 % of the total. 45% were single, whereas 37% did have a partner. 53% lived with relatives and 13% lived alone. Treatments: mood stabilizers 86.7% (38.8% just lithium; 37.8% just antiepileptic medication; 10.2 % both). Antipsychotic drugs: 98% (80.6% typical; 39.8% atypical and 22.4 % combined). Antidepressants: 5.1% (3.1% SSRI's, 1.0% TCAs, 1.0% NaSSAs).

Conclusions: we have found similar figures in gender and marital status to those published so far; coincidences have also been found in a reduction of lithium use, in considering antiepileptic medication a useful alternative, in the use of antipsychotic drugs in over three quarters of all patients. SSRIs being the antidepressants of choice albeit barely used, and, finally, regarding under use of ECT, in spite of representing possibly the most effective treatment in mania.

THE FEELING OF LONELINESS AND DEPRESSION

INSTITUTIONS
1. Moscow Research Institute of Psychiatry, Russian Federation

AUTHORS
1. Galina Petrova, pslab2006@yandex.ru

Objectives: The researches of the relationship and loneliness show that partly these feelings are coincided, but still they are different. Also we know that the patients with depression often exaggerate the negative aspects of their relationships and that’s why they feel themselves lone. In our research we investigated the relation between the feeling of loneliness, the level of depression and the characteristics of the interpersonal relationship.

Methods: 50 people from general population were tested (age - 19-74, 68% -women, 32% -men). We used Beck depression inventory (DBI), Fragebogen zur Sozialen Unterstützung G. Sommer & T. Fydrich (F-SOZU-K-22) and the Inventory of Loneliness (G. Jang).

Results: 68% of our responders have high level if the feeling of loneliness. There were positive correlations between the feeling of loneliness and the level of the depression. Also there were negative correlations between the level of depression, feeling of loneliness and perceived social support. The correlation between the depression and perceived social support varies from -0.3 to -0.8, between the feeling of loneliness and perceived social support from -0.4 to -0.8. The respondents feel dissatisfaction in some sides of the social interactions, firstly in the integration with the others and also in the possibility to accept emotional support.

Conclusions: The investigation of the correlations of the feeling of loneliness, depression and interpersonal relationships can be utilized to treat the depressions and to help people, feeling loneliness.

POST HOSPITAL EVALUATION EFFICACIOUSNESS SERTRALIN WITH OLD PEOPLE

INSTITUTIONS
1. Medical University, Psychiatrist Clinic, Kragujevac, Serbia and Montenegro

AUTHORS
1. Dusan V. Petrovic*, Dr., PhD. nicoleta@ptt.yu

Many research shows that anti-depression were more effective in healing depression with old people. Much better then the other groups of anti-depressions, there influence on improvement cog-nation function and effectively betterment energetic potential. Meaning of work: In this study we had a mark to do the valuation efficaciousness of anti-depression sertralin in population older then 65 years. In study there were 43 of them. Material and methods: In population then 65, in 43 of them, 19 were male and 24 were female. It was examine the efficaciousness anti depressions sertralin in healing major depression. Diagnostic was in base DSM IV, and of psychological scale for research depression and all clinic picture, it was Hamilton scale, Montgomery -Asbergers, and CGI. The result of research: They indicate the mean score on HAMD scale was 22±3. On Montgomery HAMD was 16±1, Montgomery 19±2, CGI 3, and after 8 weeks HAMD 10±1,Montgomery 13±1,and on CGI 2. Remark: In post hospital period of 8 weeks, test has been done after 4 and 8 weeks. Conclusion: Results of research show good efficaciousness sertralin in healing depression in population older then 65 years.

Misconception about mental disorders still prevailed among the general public. The stigma of psychiatric disorder is mainly reflected in knowledge about mental illness and attitudes toward people with mental illness. Public prejudice and self-stigma may provide equally large barriers to achieving and relishing life opportunities. The stigma process sets of by recognizing and labelling a difference between a person and other people. The next step involves the linking of the labelled person with the negative stereotypes that predominate in society about this group of people. The stigma has different components: 1) labelling; 2) stereotyping; 3) separating; 4) status loss and discrimination. The stigma process culminates in that the person concerned is exposed to different forms of discrimination and the negative social consequences resulting from this. There is difference between individual and structural discrimination as well as self-stigmatization. For anxiety disorders is very important third type. They employs various – most like I to be dysfunctional - strategies, to deal with the label and anticipated discrimination, e.g. secrecy or withdrawal, which (together with the negative self-conceptions and devaluing experiences) led to negative consequences on self-esteem, working ability, social functioning, and network ties. Finally, the individual becomes more vulnerable to a worse course of illness. Current attitude research mainly took an interest in schizophrenia and depression.

Background: Within a decade, the Repetitive Transcranial Magnetic Stimulation (rTMS) was being used to treat depression and schizophrenia. Antidepressant response has been reported in open and double-blind, sham-controlled studies of depression. Less is known about rTMS efficacy in the obsessive compulsive disorder.

Method: The aim of the randomized, double-blind, sham controlled study was to compare the 2 and 4 week efficacy of the 10 sessions rTMS with sham rTMS in serotonin reuptake inhibitor resistant OCD patient. Thirty seven right-handed patients were randomly assigned to either active rTMS or to sham. Active rTMS with the frequency of 1 Hz at 110% of motor threshold was administered over the left dorso-lateral prefrontal cortex. The same time schedule was used for sham administration. Thirty three patients finished the study, three patients’ dropped out at the beginning. Psychopathology was assessed by CGI, HAMA, Y-BOCS and BAI before the treatment, immediately after the experimental treatment, and 2 weeks after by an independent reviewer.

Results: Both groups improved during the study period but the treatment effect did not differ between them in any of the instruments.

Conclusion: Low frequency rTMS administered over the left dorso-lateral prefrontal cortex during 10 daily sessions did not differ from sham rTMS in facilitating the effect of serotonin reuptake inhibitors in OCD patients.

Background: The Repetitive Transcranial Magnetic Stimulation (rTMS) can modulate the cortical activity. The goal of our study was to assess whether the rTMS would facilitate effect of serotonin reuptake inhibitors in patients suffering from panic disorder.

Method: Fifteen patients suffering from panic disorder resistant to serotonin reuptake inhibitor (SRI) therapy were randomly assigned to either active or to sham rTMS. The aim of the study was to compare the 2 and 4 weeks efficacy of the 10 sessions 1 Hz rTMS with sham rTMS add on SRI therapy. We used 1 Hz, 30 minutes rTMS, 110% of motor threshold administered over the right dorso-lateral prefrontal cortex (DLPFC). The same time schedule was used for sham administration. Fifteen patients finished the study. The psychopathology was assessed using the rating scale CGI, HAMA, PDSS and BAI before the treatment, immediately after the experimental treatment by an independent reviewer.

Results: Both groups improved during the study period but the treatment effect did not differ between groups in any of the instruments.

Conclusion: The low frequency Repetitive Transcranial Magnetic Stimulation administered over the right dorso-lateral prefrontal cortex after 10 sessions did not differ from sham the repetitive Transcranial Magnetic Stimulation that was add on serotonin reuptake inhibitors in patients suffering from panic disorder.
